Telegraph in Argentine Republic.—The government telegraph plant of the Argentine Republic comprises 650 offices, 15,900 miles of pole line and 39,370 miles of wire. Private companies operate 1,892 offices, 20,725 miles of pole line and 69,017 miles of wire. On the government lines Morse apparatus is used, single and duplex; the Wheatstone system is also in operation, both single and duplex, also a quadruplex circuit. The quadruplex is the invention of Mr. Augustin Sal, Inspector-general of government telegraphs, Buenos Ayres. It works on a circuit of 217 miles of iron wire 4.5 millimeters in diameter of 4,000 ohms resistance, and will work on a similar wire 375 miles in length. Mr. Sal states that the No. 2 side works as fast and as smoothly as does the No. 1 side, there being no broken signals.

Turner Monument Fund.

At the Boston meeting of the Association of Railway Telegraph Superintendents, June 26-30, the Turner monument project will receive especial attention. It was at the last meeting of the association, in Los Angeles, Cal., in June, 1910, that the idea was put into concrete form and launched into existence. The movement was later endorsed officially by the Old Time Telegraphers' and Historical Association at its annual meeting in Chicago, September 8-10, 1910, and a joint committee composed of members from both organizations was appointed to solicit subscriptions to defray the cost of the monument, which will be about $3,000. Up to the present about $1,600 have been received toward the fund, and it is expected that the balance will speedily be provided.

The committee in charge of the monument fund consists of: E. P. Griffith, superintendent telegraph, Erie Railroad, Jersey City, N. J., chairman; Charles Selden, superintendent telegraph, Baltimore & Ohio Railroad, Baltimore, Md.; J. B. Taltavall, Telegraph and Telephone Age, New York; E. A. Chenery, superintendent telegraph, Missouri Pacific Railroad, St. Louis, Mo.; W. J. Camp, electrical engineer, Canadian Pacific Railway, Montreal, Canada; Col. W. B. Wilson, president Old Time Telegraphers' and Historical Association, Holmesburg, Philadelphia; F. J. Scherrer, secretary Old Time Telegraphers' and Historical Association, New York. All remittances should be made to Mr. J. B. Taltavall, Telegraph and Telephone Age, 253 Broadway, New York, who has been elected treasurer of the fund. All contributions are acknowledged in the columns of Telegraph and Telephone Age, and the funds deposited with the Washington Trust Company, New York, as soon as received.

In our issue of May 1 we acknowledged the receipt of $155 from Mr. C. F. Ford, of Central Valley, N. Y., from 145 employes of the Harriman Estate, at Harriman, N. Y. The following is a list of the individual contributions which made up this amount: C. F. Ford, $5.00; Richard Rose, $1.00; J. B. Ford, $1.00; G. W. Birdsall, $1.00; G. H. Wilkes, $1.00; C. E. Jones, $1.00; I. W. Maudiyo, $1.00; C. Herbert Ford, $1.00; Robert Weyant, $0.50; W. B. Wilkes, $0.50; John Potter, $1.00; F. B. Burgess, $1.00; H. C. Thorne, $1.00; J. Kock, $0.50; R. Grunott, $0.75; H. Totter, $0.75; C. Kauptot, $0.75; A. Lamprecht, $0.50; A. Rominy, $0.25; F. Detlef, $0.50; F. Hilzinger, $0.50; A. Puggiotto, $0.50; Cris Buff, $0.50; C. Magliola, $0.50; D. Bernard, $0.50; C. Robertson, $0.50; C. Drening, $0.50; A. Eleisburg, $0.50; Ray Pfister, $0.50; F. V. Custard, $1.00; H. Kamphauser, $1.00; J. E. Corley, $0.50; T. Gregory, $0.50; Wm. Thom, $1.00; Chas. Kansen, $0.50; E. Wahner, $1.00; E. B. Anderson, $1.00; Frank Conklin, $0.50; Nick Clark, $1.00; R. F. Weygant, $1.00; A. Treptri, $1.00; Jas. Potter, $1.00; Nelson Degraw, $0.50; Edw. Dunn, $1.00; H. Bullwuckle, $1.00; M. Fahlman, $1.00; A. H. Walsh, $1.00; R. Bullwuckle, Jr., $1.00; Frank Decker, $1.00; Bert Jones, $0.50; F. Schroon, $1.00; M. Mazzone, $1.00; G. Marcksino, $1.00; Vincent Viscidy, $1.00; P. Aliano, $1.00; H. Knapp, $1.00; G. Kreies, $1.00; J. S. Baird, $1.00; A. H. Travers, $1.00; Reuben Ayres, $0.50; B. King, $1.00; C. A. Solman, $1.00; F. E. Wooly, $1.00; Valentino Dubburo, $0.50, all of Central Valley, N. Y.; A. D. Cole, $0.50; a mason friend, $1.00; C. Post, $1.00; M. Weyant, $1.00; a mason friend, $0.50; Jack Redner, $1.00; Thos. Turnbull, $1.00; E. Heiniske, $2.00; B. Stein, $0.50; A. Mielert, $0.50; A. W. Henning, $0.50; H. Schmock, $0.50; H. Veith, $0.50; S. D. Gordon, $1.00; D. Turnbull, $1.00; J. Conklin, $0.50; Geo. King, $1.00; Alf. Moshes, $1.00; R. Herbert, $1.00; A. Shire, $1.00; C. Hollman, $1.00; Geo. Bowen, $1.00; Frank Ballard, $1.00; F. A. Schultz, $1.00; Thos. Baird, $1.00; W. Berry, $1.00; Geo. Cruickshank, $1.00; J. B. Otis, $2.00; W. H. Crane, $1.00; I. Ellis, $1.00; V. Troiano, $0.50; W. B. Birdsall, $2.50; J. E. Myer, $2.50; T. B. Earl, $2.00; Moses Beal, $1.00; Chas. Carpenter, $1.00; cash, $1.00; J. S. Conklin, $1.00; I. D. Smith, $1.00; W. Goodfellow, $1.00; J. A. Cornelius, $1.00; Thomas Monhan, $1.00; Charles Beams, $1.00; J. Babchak, $0.50, all of Harriman, N. Y.; B. F. Shuit, Monroe, N. Y., $1.00; E. P. Schultz, $1.00; I. T. Hunter, $1.00, Highland Mills, N. Y.; C. E. Alduci, $1.00; C. H. Howell, $1.00, Cornwall-on-Hudson, N. Y.; C. E. Weeks, $0.50; H. W. Green, $0.50, Highland Mills, N. Y.; E. P. Runyon, Vails Gate, N. Y., $1.00; H. Hunter, $0.50; Theo. Barton, $0.50, Highland Mills, N. Y.; Chas. Hinn, $1.00; C. Johnson, $1.00, Cornwall, N. Y.; A. Eversin, $1.00; S. P. Shelling, $1.00; Gus. Johnson, $1.00, all of Newburgh, N. Y.; E. D. Taylor, $0.50; A. J. Wells, $0.50, Highland Mills, N. Y.; D. W. Wenker, $1.00; Ted Viner, $0.50; A. G. Klock, $1.00; W. A. Viner, $1.00, Arden, N. Y.; Edw. Hand, Cornwall, N. Y., $1.00; C. C. Rumsey, $25.00; A. B. Schoonmaker, $1.00, Arden, N. Y.; J. F. Gaylor, New York, $1.00; F. Keishaw, Highland Mills, N. Y., $1.00; J. Kopchak, $1.00; Pasgalo Maguyo, $1.00; Walley Ventura, $1.00; Giovanni Ventura, $1.00; Chas. Ventrano, $1.00; Jimmy Di Donato, $1.00; Brionauito Commak, $0.50; John Flovian, $1.00; Carrlo Coipakfere, $0.50, all of Sloatsburg, N. Y.

Contributions received up to date are as follows: Previously acknowledged, $1,544.25. Okonite Company, New York, $50.00. Total, $1,594.25.

Mr. H. A. Tuttle, president and general manager of the North American Telegraph Company, Minneapolis, Minn., in renewing his subscription for another year writes: "I certainly shall take great pleasure in recommending Telegraph and Telephone Age to any of my friends interested in this kind of business. I greatly enjoy the paper, now, as I have for many years in the past. I wish you every success."

Digitized by Google

Study of the Quadruplex.

The duplex and quadruplex of today are, in principle, the same as they were in the beginning, the differences being largely due to refinement of details. An excellent book on the quadruplex is that of Maver and Davis', "The Quadruplex," which was published many years ago but which is still a valuable work on the subject. The chief feature of the book is its easy method of describing the principles underlying the duplex and the quadruplex, and after these have been mastered the minor differences in the present day instruments can be readily understood.

In our department headed "Questions to be Answered" we are now using "The Quadruplex" as a basis for questions, in the same manner as was done with Jones' book of diagrams.

Besides the duplex and quadruplex the Wheatstone system of telegraphy is fully described and illustrated, and a chapter on repeaters gives a very clear explanation of the principal repeaters in use in this country.

From the chapter headings an idea of the scope of the work may be obtained. Chap. 1. Development of the Quadruplex; 2. Introduction and Explanatory; 3. The Transmitter, Rheostat and Condenser; 4. Stearns Duplex; 5. Instruments of the Polar Duplex; 6. The Polar Duplex; 7. The Quadruplex; 8. The Dynamo-Electric Machine in Relation to the Quadruplex; 9. The Practical Working of the Quadruplex. The two last chapters are on Telegraph Repeaters and the Wheatstone Automatic Telegraph. Copies of this book may be obtained at $1.50 each by addressing Telegraph and Telephone Age, 253 Broadway, New York.

"Touching" the Western Union.—The Western Union Telegraph Company is now good for a "touch," is the way some of the employes refer to the company's recent loan order.

The Yaquy Delta Land and Water Company has been incorporated at Dover, Del., with an authorized capital stock of $12,000,000. It will enter Mexico with railroad and telegraph lines.

The Edison Storage Battery.—Mr. Frank L. Dyer, for many years in charge of Mr. Thomas A. Edison's patent and business interests, presented a paper on "The Edison Storage Battery—Its Production and Application," before the New York Electrical Society May 18th.

Duty on Glass Insulators.—The Board of United States General Appraisers at New York decided recently that colored glass insulators in contradistinction to insulators colored are subject to a duty of 45 per cent. ad valorem instead of 60 per cent., thus reversing the appraisal of the Collector of Customs.

Philadelphia Local Telegraph Company.—At the annual meeting of the Philadelphia Local Telegraph Company, Philadelphia, Pa., Mr. Theo. N. Vail was elected president; Mr. Belvidere Brooks, vice-president; Mr. John W. Reed, general manager, and Mr. William P. Wheatland, secretary and treasurer.

The Child Labor Law Applied to Operators.—It appears that some of the states in enforcing their laws against employing messenger boys under eighteen and twenty-one years to deliver messages after 9 p. m. have enlarged their authority to include telegraph operators. Some telegraphers slightly under eighteen years of age have been denied the right to work at night, and others under twenty-one years have been prevented from working in the evening in states where the laws prohibited such employment. A night operator in an eastern city nearly lost his position recently because it was thought that he was not eighteen years of age. An agent of the department of public instruction investigated the matter and it cost the taxpayers a little money to find out that the suspect was in reality over eighteen years of age.

An American Consul in Amazonia is the title of a new book by Major J. Orton Kerbey, the well-known old-time and military telegrapher and ex-United States Consul at Para, Brazil. It is an interesting story of Major Kerbey's experiences and observations of South American life during his stay at Para as United States Consul. He describes the country and the customs and character of the people in a wealth of detail. The book is dedicated to Mr. Andrew Carnegie of whom there is a frontispiece in sepia tint. Major Kerbey is an easy and pleasant writer, and his story of life on the equator makes an exceedingly interesting narrative. He has illustrated his book very liberally with Brazilian views and portraits. The work contains 370 pages and is sold at $2.50 per copy. Copies may be obtained through Telegraph and Telephone Age, 253 Broadway, New York.

Old Timers' and Military Telegraphers' Convention.—The Old Time Telegraphers' and Historical Association and the Society of the United States Military Telegraph Corps will hold their joint convention at Atlantic City, N. J., September 5, 6 and 7, and a large attendance is looked for. Active preparations are being made to make the meeting a success in all respects and the secretaries of both organizations are busy on the plans. The headquarters will be at the Marlborough-Blenheim, which is one of the finest hotels at that famous seaside resort. Col. W. B. Wilson, Holmesburg, Pa., is president of both associations, and Mr. F. J. Scherrer, 30 Church Street, New York, is secretary of the Old Time Telegraphers' and Historical Association. Mr. David Homer Bates, 658 Broadway, is secretary of the Society of the United States Military Telegraph Corps. Mr. G. W. Deetz, manager of the Western Union Telegraph Company, Atlantic City, N. J., is a member of the executive committee and has charge of many of the local arrangements.

Obituary.

W. F. Burton, aged 45 years, formerly operator at Nashville, Tenn., died at that place May 11.

Geo. F. Lehmer, aged 64 years, formerly manager of the Western Union Telegraph Company at Omaha, Neb., died May 17.

Wm. J. Lee, aged 40 years, operator for the Associated Press and Western Union Telegraph Company at Washington, D. C., died in that city May 20.

Frank J. Brown, aged 60 years, formerly train dispatcher for the Michigan Central Railroad, at Jackson, Mich., died at Ypsilanti, Mich., April 28.

Samuel J. Dennis, aged 69, formerly connected with the auditing department of the Western Union Telegraph Company, New York, died on May 15.

G. J. Lawrence, a retired business man of Albion, N. Y., an old-time telegrapher, and a member of the United States Military Telegraph Corps, died in that place May 10, at the age of 76 years. This is the fifteenth death in the membership of the United States Military Telegraph Corps since the Chicago reunion last year.

William Macfeely, who died in Washington, D. C., February 6 last, was one of the early telegraph operators in the national capital, having commenced the work in 1854, when he was eighteen years of age. He remained with the telegraph company about seven years, and then entered the service of the government, in which he continued up to the time of his death. For more than forty years he held a responsible position in the Treasury Department. He was never married. The interment was at his native place, Carlisle, Pa.

Annie Elizabeth Clark, wife of Dr. James J. Clark, Washington, D. C., an associate of Prof. S. F. B. Morse, died in Washington, May 23. Dr. Clark is one of the few men who were intimately associated with Prof. Morse in the work of developing his telegraphic inventions. Dr. Clark's father was a skillful and successful mechanician and clock maker in Philadelphia, and young Clark was his partner and successor. They devised the first register with solid side plates, supporting all the working parts, a plan universally followed thereafter. They also made the "harp register," the design for which was drawn by the late J. D. Reid in their shop. Dr. Clark has always retained his interest in telegraph matters and is widely known among members of the fraternity and is an occasional contributor on historical matters in these columns.

Martin W. Barr, a forty-niner of the telegraph, and a well-known newspaper man in Washington, D. C., died in that city May 11, at the age of 84 years. Mr. Barr entered the telegraph service at Wheeling, W. Va., in 1847 and later in the same year he opened the first telegraph office at Columbus, Ohio. In 1848 he was placed in charge of the Louisville, Ky., office of the Louisville and St. Louis Telegraph line, which position he held until 1855, when he resigned to enter the newspaper field. He enlisted in the Confederate army during the civil war and received the rank of major, his duties being to intercept the news of the northern army. Mr. Barr was connected with the Southern service of the Associated Press at Washington for many years and afterwards held a position as proof-reader in the Government printing office. He retired from active service several years ago. Mr. Barr was a man of gentle nature and was highly esteemed by those who knew him.

The Late Fred Catlin.

BY W. H. ALLEN, WASHINGTON, D. C.

The article in your issue of May 1 respecting the passing away of our old friend, Fred Catlin—one of the best of fellows and as fine a telegrapher as ever touched a Morse key—recalls an incident in which Mr. Catlin figured, the other participant being Mr. P. V. De Graw, now fourth assistant postmaster-general at Washington, D. C. It was in the seventies. De Graw and Charlie Moore were the Philadelphia night regulars on the New York-Philadelphia short wires, and Mr. George M. Eitemiller and Mr. Walter P. Phillips manned the two circuits at the New York end. Between 6 and 9 p. m. daily several hundred private messages and cables were exchanged on these two circuits, and the caliber of these men is sufficient proof that the circuits were worked about the fastest of any out of either office. As the boys used to say in referring to these wires, "Morse is clipped to a finish."

The incident referred to happened one night when Mr. Phillips was away and a new man, a stranger, was put on one of the wires to send to De Graw. Matters did not run smoothly and the late Tom Dolan, the night manager at New York, gave the wire especial attention. Noting several breaks by De Graw, he called upon the night chief in the Quaker City, the late J. E. Zeublin, for an explanation, remarking that the business was not being worked off with the usual facility. Zeublin listened; noticed the breaks upon the part of the receiver, De Graw; stepped over and in his usual lovable manner asked of De Graw what was the trouble. De Graw replied, "No trouble, except that I cannot read the sending."

"Let me try it," said Zeublin, who sat in without giving the relief sign. He found it impossible to decipher the peculiar sending and reported the facts to Manager Dolan, adding: "If you have any real good senders over there put one on that wire and I will guarantee that the business will be handled with dispatch." Dolan said he thought the trouble was with the receiver, "but," he added, "we shall see. I will put a man on there who will clear the wire in thirty minutes. Now it is up to your end to do your part."

"All right," replied Zeublin, "let 'em come."

A moment later Fred Catlin at New York asked of Philadelphia, "Who's there?" "De," was the reply. "Hello old boy," said Catlin, "what's the matter; this circuit is piled up and I have instructions to clear it up in half an hour. Are you ready?"

Digitized by Google

"All ready, go ahead," was the reply.

Catlin ran off twenty-eight messages as they came, long and short, in twenty-five minutes, without hearing a sound from Philadelphia and then closed his key. "De" was the only signal that came back, indicating that the messages had been received all right.

It turned out that Dolan and Zeublin had cut in and listened to the work, and both chiefs assured young De Graw that he was all right, and that the circuit should thereafter always be manned with "Morse clippers." And so it was.

Mr. De Graw's version of the incident is that it was only a question of being able to drive a rapid pen, as there could be no criticism of the Morse characters employed by Catlin, they being simply perfect. "In my judgment," said Mr. De Graw recently, in reference to this matter, "Fred Catlin, Bert Ayres, Eddie Boileau, and George Eitemiller were in those days the finest Morse senders in the world."

Decorating the Morse Statue.—The statue of Prof. S. F. B. Morse, in Central Park, New York, was, as usual, decorated on Memorial Day. Mr. M. H. Kerner, of the Western Union Telegraph Company, New York, has supervised this work for the past sixteen years and he has been faithful to his trust. Hereafter the expenses of decorating the statue will be borne by the Morse Electric Club.

Trade Notes.

The Randall Telephone Manufacturing Company, which is to exploit the telephone inventions of Mr. C. Adams-Randall, New York, has opened offices at 291 Broadway, corner Reade Street.

Mr. C. Brandes, 111 Broadway, New York, maker of high-grade receivers for wireless telegraphy and telephony, has just issued a new pamphlet, which gives a little story on long-distance wireless receivers. Mr. Brandes will mail a copy to any address on receipt of a two-cent stamp.

Removal of Gamewell Fire Alarm Telegraph Company's Office.—The Gamewell Fire Alarm Telegraph Company, New York, has moved its executive offices from 19 Barclay Street to 30 Vesey Street. The company will occupy the entire fourteenth floor of this newly erected modern fireproof building. The officers of the Gamewell Company are: W. H. Woolverton, president; Wm. Gellatly, vice-president and general manager; Charles W. Cornell, secretary, and W. W. Bowes, treasurer.

O. R. T. Convention.—At the biennial convention of the Order of Railway Telegraphers, held at Toronto, Ont., May 8-17, all of the present officers were re-elected as follows: H. B. Perham, president; J. A. Newman, first vice-president; T. M. Pierson, second vice-president; D. Campbell, third vice-president; J. J. Dermody, fourth vice-president; L. W. Quick, grand secretary and treasurer. The present board of directors was also re-elected. It was decided to hold the next convention in Baltimore, Md., in 1913. The twenty-fifth anniversary of the Order of Railroad Telegraphers will be celebrated in Cedar Rapids, Iowa, during the present month.

T. M. B. A. Assessment.—Assessment No. 524 has been levied by the Telegraphers' Mutual Benefit Association to meet the claims arising from the deaths of Wm. H. Stevens at Buffalo, N. Y., Joseph Knittle at Brooklyn, N. Y., John Fitzpatrick at Springfield, Mass., Alfred G. Trulan at Montpelier, Vt., Samuel C. Suydam at Canandaigua, N. Y., and James M. Daniel at Georgetown, Tex.

LETTERS FROM OUR AGENTS.

ATLANTA, WESTERN UNION.

The ladies' "rest room" in connection with the operating department has been furnished with a couch, a generous number of easy chairs, etc., giving it a very cozy and homelike appearance and adding much to the comfort and convenience of the employes. The men's "rest room" has been furnished with an oak dining table, comfortable lounging chairs, a writing table, bookcase, etc. This room is also used by the classes in electricity, which are making good progress and are enthusiastically attended.

Mrs. C. E. Johnson, formerly of 195 Broadway, New York, is a recent addition to the operating force.

Messrs. E. E. Cunningham, D. Terry and F. Gittus have recently been appointed assistant repeater chiefs.

At a conference of the heads of divisions of the Atlanta operating department, held in Superintendent E. E. Williams' office, the following were present: Mr. W. C. Hair, general traffic chief; Mr. W. O. Ballard, general wire chief; Mr. T. E. Argo, general repeater chief; Mr. S. H. Woodruff, general printer chief; Messrs. W. A. Reynolds, E. Waldron, J. F. Morey, wire chiefs; Messrs. W. W. Crudden, E. T. Krebbs, E. E. Cunningham, J. P. Brown, J. L. Walling, D. Terry, F. W. Gittus, repeater chiefs; Messrs. R. E. Satterwhite, J. T. Goodrum, J. D. Prather, O. T. Hughes, traffic chiefs; Mr. E. G. Clinkscales, night repeater chief; Mr. A. H. Condra, night chief operator, and Mr. H. K. Griffin, chief operator. Each of those present was requested to voice his views as to methods for better co-operation within and without his own department; also anything which seemed to result in a benefit of the service. Numerous valuable suggestions were made.

It must be very gratifying to General Superintendent H. C. Worthen to note the enthusiastic interest taken in the company's affairs by his subordinate officials. Chief Operators F. R. Vaile of Richmond, Va., W. R. Jackins of Charlotte, N. C., D.

Digitized by Google

G. Breed of Louisville, Ky., G. W. Hammill of Nashville, Tenn., and H. K. Griffin of Atlanta recently met at Atlanta in conference as to the best methods of maintaining closer co-operation and harmony between their respective offices; also for a comparison of working methods, etc. Each one expressed himself to have been benefited and believed a better service would result. The telegraphic spirit of Atlanta is a real live quantity and there are fifty men now in the Atlanta office who will be heard from later as electrical engineers.

Mr. B. P. Hancock, district traffic superintendent, has returned from a trip of inspection through Tennessee.

General Superintendent H. C. Worthen of Atlanta, Ga., and District Commercial Superintendent J. R. Terhune of Nashville, Tenn., made a business trip through Mississippi recently.

In regard to the electrical class organized among the Western Union employes at Atlanta, Ga., which was referred to in our issue of March 16, superintendent E. E. Williams, at that point, says: "We are glad to note that our employes are meeting our efforts half way, and we anticipate results that will be highly gratifying to the men themselves, and also to the company. Our employes in the South are waking up to the opportunity for advancement being offered by the liberal policy of the Western Union Company, which is constantly on the lookout for efficient men and women."

Mr. Williams states that Mr. Jos. Marshall, chief operator at Charleston, S. C., has started a class composed of his own subordinates, and is doing fine work.

SAN FRANCISCO, WESTERN UNION.

Mr. Frank Morris, formerly eastern and overland division chief, who recently resigned and went to Los Angeles as assistant chief operator, has resigned at the latter place and gone to his ranch near Seattle, Wash. Mr. Charles Rawlinson, formerly of Indianapolis and Cleveland, takes Mr. Morris' place as chief of the overlands.

Mr. C. E. Paine, formerly with the Atchison, Topeka & Santa Fe Railway at Los Angeles, takes the North and South coast wires. Mr. Paine has recently been acting as traffic chief nights. He is relieved by Mr. T. McGunness, formerly manager at Ogden, Utah.

NEW YORK, WESTERN UNION.

Mr. W. J. Van Slyke, for many years connected with the marine department in this office, died on May 11. Interment was at his old home in Stuyvesant, N. Y. Mr. Van Slyke was esteemed for his quiet and gentlemanly bearing.

Mr. Cyrus Cole, a veteran employe of this office in connection with "Clark's" department, died on May 10.

NEW YORK, POSTAL.

The New York Postal Electrical Society has a membership of forty and is doing excellent work under the guidance of the instructor, Mr. Donald McNicol of the electrical engineer's staff. After ten weeks' study thirty members took the examination, and twenty-three of them earned over 200 points out of a possible 270. A list of the examination questions shows a wide scope of instruction.

Martin's Double Lever **VIBROPLEX, $8.00** f. o. b. D. C. DeLany, 15 S. Broad St., Atlanta, Ga.

FOR SALE—A Bunnell galvanometer, complete in leather case, with resistance coils and connections for Wheatstone bridge measurements. Must be disposed of immediately to close an estate. Cost over $100.00. Will sell for $35.00. Address "Galvanometer," care Telegraph and Telephone Age, New York.

The Telegraphers' Mutual Benefit Association, 195 Broadway, New York, has for nearly half a century proclaimed the absolute necessity of life insurance and provided a safe and economical form of protection for the home and family within the means of every telegraph and telephone employe. A certificate of membership affording protection of $500 or $1,000, or both, is easily obtainable by every one in good health engaged in telegraph or telephone service, either commercial or railroad, between the ages of 18 and 45, and should be held by all employes not otherwise provided with adequate life protection.

TRANSMITTING MACHINES

I am placing on the market improved YETMAN TRANSMITTING TYPEWRITERS, and KEYBOARD TRANSMITTERS without typewriting features. Am prepared to exchange, repair or rebuild all old machines. Write for catalogues and particulars to

James Uncles, NORTH ADAMS Massachusetts

Rubber Telegraph Key Knobs.

No operator who has had to use a hard key knob continuously should fail to possess one of these flexible rubber key caps, which fits snugly over the hard rubber key knob, forming an air cushion. They render the touch smooth and the manipulation of the key much easier. Price, fifteen cents.

J. B. Taltavall, TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

Every one engaged in telegraphy and telephony should be a constant reader of TELEGRAPH AND TELEPHONE AGE. It gives the latest news in both these fields. Subscribe now. Subscription price, $2.00 per year.

The great telegraphic song hit,
"SEND ME A NIGHT LETTER, DEARIE."
Good, catchy music; beautiful title design magnificently printed in colors. Title contains night letter. Sung all over New York, 17c. by mail. All popular music sent by mail.
B. L. BRANNAN,
195 B'way, N. Y.

SOME POINTS ON ELECTRICITY.

BY WILLIS H. JONES.

ELECTRO-THERAPEUTICS.

Electro-therapeutics is a term used to designate the treatment of disease by means of electricity, and this method of treating disease has been used with varying results as far back as means of generating electricity have been known. During the early period the method employed consisted principally in stimulating the organs of the human body by means of "shocks" produced by the discharge of Leyden jars and frictional machines. With every new method devised for generating an electric current a new way of application and treatment was tried, with the result that to-day electro-therapeutics has become a very valuable adjunct to medical science when properly handled, while at the same time it is the source of much harm in the hands of laymen.

The purpose of this article is to call attention to the too common practice on the part of the general public of indiscriminately resorting to home treatment by electricity for each and every ill with which one may become temporarily afflicted.

A few words describing the effect produced in the human body by the passage of an electric current through it should make this warning well worthy of consideration.

When a current enters the body several different effects are produced, the principal ones being magnetic, electrolytic, osmotic and cataphoric. The first two play so little a part that they may be left out of the consideration.

The electrolytic, or decomposing factor, however, is the basis of electro-therapeutics. We all know that when a fluid or solution is decomposed by a current the product of such decomposition appears only at the electrodes, yet all along the route between the electrodes there is a movement of the separated ions, the positive going in one direction and negative in the opposite. Hence when a current passes through the moist human tissue there is an electrolytic effect created therein throughout the entire route, and the aim of electro-therapeutics is to cause these migrating ions to carry into the body, and thus reach the diseased parts, medicinal solutions rubbed into the skin where the current enters. Treatment of this kind is called cataphoric and is the principal method now employed.

Now this all seems like a very simple and harmless method of cure, and one that anyone might try with impunity. But let us see what chance the layman has of deriving any beneficial result, even if he escapes actual harm.

In the first place he does not know that the electrolytic effect caused in the human body engorges certain portions of the body at the expense of depleting the fluids in others. There can be no gain in one way without a corresponding loss of strength in another. Fortunately healthy tissue can withstand considerable loss without the individual experiencing any appreciable harm, but diseased parts are readily responsive. Some such parts may require stimulation, while the stimulation of the same parts in another instance might prove fatal. How is the layman to know which remedy is correct for each particular case?

Again, assuming that he does know, how can he tell the proper volume or strength of the current required for producing good results, or how long a time to continue the treatment?

Furthermore, with his limited knowledge of anatomy, what chance has he of connecting the electrodes so that the current will actually reach the diseased parts? He does not know that the greater volume of current will be diverted through his body by the shortest path, according to Ohm's law. The result is that in the majority of cases of home treatment very little current actually reaches the diseased parts, but spreads out through other portions of the body, where it may be either harmless or dangerous, according to the conditions of the other parts coming under its influence.

During the early stages of electric treatment a certain amount of ignorance was to be expected, as everything was more or less experimental, but there is no excuse for guessing about it now. Medical batteries or magnetos are very useful, but the physician should advise their use, not the layman; they may or may not be the remedy required.

Digitized by Google

ELECTRIC CAUTERY.

Electro-therapeutics also plays an important part in surgery. Owing to the ease with which an electric current heats a metallic wire to incandescence, advantage has been taken of this to construct surgical knife blades of platinum, which readily become incandescent when a large volume of current is caused to flow through them.

Such knives are obviously of a superior order, compared with the old style, as they cauterize the wound at the same time they cut out and remove diseased tissue.

Recent Telegraph and Telephone Patents.

ISSUED MAY 16.

992,165. Telephone System. To H. P. Clausen, Chicago, Ill.

ISSUED MAY 23.

992,791. Wireless Telegraphy. To J. F. McElroy, Albany, N. Y.

992,836. Party Line Ringing System. To C. S. Winslow, Chicago, Ill.

993,024. Coherer. To E. J. Burke, New York.

ISSUED MAY 30.

993,442. Telegraphy. To J. A. Esslinger, Washington, D. C.

993,975. Telephone Support. To Charles E. Flynn, Vale, Ore.

994,079. Telegraph Transmitter. To B. P. Hayes, Topeka, Kan.

Personal.

Miss Hattie M. L. Roth, for several years bookkeeper for TELEGRAPH AND TELEPHONE AGE, was married to Mr. H. J. A. Schneider, of New York, on June 1.

Mr. W. H. Hurst, president of the Stock Quotation Telegraph Company, New York, has returned from England where he has been on business since April.

Mr. Melville E. Stone, general manager of the Associated Press, New York, will address the meeting of the Michigan members of the association at Grand Rapids, on June 16.

Mr. Ralph W. Pope, an old-time telegrapher and for over 25 years secretary of the American Institute of Electrical Engineers, New York, is the subject of an interesting sketch in the Columbus, Ohio, *Dispatch* of May 28.

Mr. Robert T. Lincoln, president of the Pullman Company, Chicago, Ill., has resigned that office. He was subsequently elected chairman of the board of directors of the company. Mr. Lincoln is a director of the Chicago Telephone Company and is a son of the late President Abraham Lincoln.

Mr. John S. Ernest, a well-known operator of St. Louis, Mo., and formerly of Virginia, is proprietor of *The Sunday Telegraph* of that city, which is devoted to baseball and other sporting news. He also represents twelve out-of-town papers in baseball matters, and, besides, carries on other lines of trade.

Mr. Frank S. Gannon, whose office is at 2 Rector Street, New York, is an old-time telegrapher, and has held important official positions on various railroads in the eastern and southern states. Mr. Gannon devotes himself to technical work in examinations and appraisals of railway properties and as advisory counsel.

Mr. Emmett Howard, an old-time telegrapher, ex-confederate operator and manager of the Western Union Telegraph office at Memphis, Tenn., for over twenty-five years, has gone to Los Angeles, Cal., for the benefit of his health. Mr. Howard has been for the past seven years in the insurance business and his associates at Memphis tendered him a farewell luncheon prior to his departure for California.

Postal Telegraph-Cable Company.

EXECUTIVE OFFICES.

Mr. E. J. Nally, vice-president and general manager, has returned to his office after a brief business trip to Chicago.

Mr. H. A. Tuttle, president of the North American Telegraph Company, Minneapolis, Minn., was a recent New York visitor.

Mr. E. B. Pillsbury, general superintendent, New York, was a recent visitor at Buffalo, N. Y.

Mr. A. L. Edgecomb, district superintendent at Boston, has returned to duty after an absence of several months on account of illness.

Mr. Isaac Smith, superintendent of tariffs, New York, was married on June 1 to Miss Jennie Emilio Lewis, of Jersey City, N. J.

Mr. M. J. O'Bryan, manager of the Plattsburg, N. Y., office, is on a six-months' leave of absence on account of sickness. He is relieved by Mr. C. M. Baker.

Mr. H. H. Hall, manager of the Postal Telegraph-Cable Company at Ashtabula, Ohio, is visiting New York friends and relatives.

Mr. Richard A. Shepard, assistant manager of the Poughkeepsie, N. Y., office of the Postal Telegraph-Cable Company, has been appointed manager.

Mr. J. C. McIntyre has been appointed manager of the Rome, N. Y., office, vice E. J. Nerburn, resigned.

Messrs. E. E. Heasly and T. J. Hoge, repeater chiefs, and Mr. G. W. Dull, assistant chief operator at Pittsburg, Pa., and Mr. H. L. Vincent, quadruplex chief at Boston, were recent executive office visitors.

The Postal Telegraph-Cable Company of Connecticut has qualified to do business in Vermont with office at Burlington, in charge of Mr. F. F. Bradish. The capital stock of the company is $30,000.

Digitized by Google

The North American Telegraph Company, H. A. Tuttle, president and general manager, is erecting a new wire from Minneapolis to Chicago to better care for the increase in the company's business.

The Postal Telegraph-Cable Company is using its new copper line between Seattle and Spokane, Wash., for simultaneous duplex and telephone operation. The composite telephone system is also being installed on the company's new line between San Francisco, Cal., and Salt Lake City, Utah. The telephone is for general use.

Western Union Telegraph Company.

EXECUTIVE OFFICES.

Mr. A. G. Saylor, general superintendent of the Eastern Division, has returned from a trip to Boston and other New England points.

Mr. T. W. Carroll, assistant to the general manager, New York, Mr. C. H. Gaunt, general superintendent, and Mr. H. F. Dodge, division commercial superintendent, San Francisco, together with several other officials of the company, visited all the important points in the Pacific Coast states recently in the interest of the service.

Mr. George M. Yorke, assistant general superintendent of plant of the American Telephone and Telegraph Company, New York, has been appointed engineer of the Western Union Telegraph Company.

Mr. W. J. Dealy, general superintendent of the Commercial News Department, New York, is rapidly recovering from a surgical operation and expects to be at his desk in a few days.

Mr. W. A. Porteous, manager of the New Orleans, La., office, accompanied by Mrs. Porteous, was a recent New York visitor.

Mr. B. F. Ragsdale, chief operator of the Augusta, Ga., office, has been advanced to the position of district manager for the state of South Carolina, with headquarters at Columbia.

Mr. George F. Stadtmiller, manager of the Erie, Pa., office, has been appointed district commercial manager of the Pittsburg district, with headquarters at Jamestown, N. Y.

Mr. J. J. Kisler has been appointed manager of the office at 174 West Street, New York, vice Mr. J. Cashman transferred to the general operating department.

Mr. D. F. Cason, former manager of the Greenville, S. C., office, has assumed the managership at Winston-Salem, N. C., vice Miss K. Mitchell, transferred to Goldsboro, N. C., Mr. J. R. Jones, manager at Goldsboro, having left the service.

Miss Estelle G. Wilson has been appointed manager of the Western Union Telegraph office at Concord, N. H., vice H. H. Morrison, deceased. Miss Wilson has been chief operator of the Concord office for several years past and the promotion is therefore a well deserved recognition of her ability.

Mr. W. D. Stead, manager of the Western Union Telegraph office at Meridian, Miss., has been transferred to superintendent Maxwell's district, with headquarters at Montgomery, Ala.

Mr. A. T. Cocke, manager of the Hattiesburg, Miss., office, has been transferred to Meridian, Miss.

Mr. J. L. Perkins has been appointed acting manager of the Hattiesburg, Miss., office.

Miss A. M. Hooks has been appointed manager of the newly-opened office at Pineville, Ky.

Miss E. G. Gillispie has been appointed manager at Winona, Miss., vice J. A. Pryor, resigned.

Mr. Charles M. Holmes has been appointed manager of the Jacksonville, Fla., office, vice C. E. Davidson, transferred to a position in the superintendent's office.

Mr. F. M. Houser has been appointed chief operator at Jacksonville, Fla., vice J. E. Rowe, transferred to Nashville.

Mr. G. W. Hammell, chief operator at Nashville, Tenn., has been transferred to Augusta, Ga.

Mr. J. E. Rowe, formerly chief operator at Jacksonville, Fla., has been appointed chief operator to succeed Mr. Hammell at Nashville.

Mr. Joseph Marshall, chief operator of the Charleston, S. C., office, has been transferred to the chief operatorship at Savannah, Ga., vice Mr. F. M. Houser transferred to Jacksonville, Fla.

Mr. H. B. Wallace is acting chief operator of the Charleston, S. C., office and Mr. W. H. Hughes is night chief operator at the same place.

The annual banquet of the Western Union Telegraph Company employes of Atlanta, Ga., was held at the Capital City Club June 8. There was a large attendance, including Mr. H. C. Worthen, general superintendent, and Mr. E. E. Williams, district commercial superintendent, Atlanta, as well as other officials of the company.

Managers from various offices in Alabama held a meeting at Montgomery, May 20, for the purpose of exchanging ideas for the benefit of the service and to become better acquainted with one another. Among those present were: S. L. Burts, district commercial superintendent, Jacksonville, Fla., and managers W. A. Sheppard, Montgomery; C. R. Hughes, Mobile; T. H. Hubert, Dothan; J. H. Purnell, Opelika; G. S. Matthews, Tuscaloosa; R. L. Smith, Talladega; O. H. Sombke, Anniston; G. R. Calvert, Birmingham; C. H. Gilbert, Huntsville; L. F. Harris, Decatur; W. A. Barrett, Gadsden, and J. M. Green, chief operator, Birmingham.

An office was opened by this company on June 1 in the Heidelburg Tower Building on Forty-second Street, New York.

The summer outing of the Morse Electric Club will be held at Donnelly's Hotel, College Point, L. I., Saturday, July 8. One of the Western Union cable steamers will be available for the use of the club to convey the members to the place of meeting.

Digitized by Google

A new uniform for the company's messengers in all the large cities has been adopted. In general it is of military design, the cloth being of a deep blue color. The letters "W. U." are embroidered in red on the shoulder straps, and the trousers are blue with red seam-stripes. The design of the cap is a combination of the latest military and automobile patterns. In the warmer sections the boys are furnished with blouses made of blue flannel with the insignia "W. U." embroidered on each sleeve.

G. M. Yorke, Engineer Western Union Telegraph Company, New York.

Mr. George M. Yorke, the newly appointed engineer of the Western Union Telegraph Company, with headquarters in New York, is yet a young man, having been born in Lowell, Mass., on April 27, 1870. He is a graduate of the Massachusetts Institute of Technology, Boston, Mass., in the class of 1893, which institution has turned out some of the ablest engineers in the United States. Mr. Yorke's business career has been wholly devoted to telephony, and he has held various positions in the engineering and in other departments of the American Telephone and Telegraph Company, being assistant general superintendent of plant of that company at the time of his appointment to be head of the engineering department of the Western Union Company. He has had an extensive engineering experience and comes to his new position well equipped. It is interesting to note in this connection that Mr. Yorke is the first one to occupy this position, which is a newly created one.

Mr. Yorke is an associate member of the American Institute of Electrical Engineers and a member of the Franklin Institute, Philadelphia.

Mr. Charles Byrd Wade, whose appointment as manager of the Western Union Telegraph Company at Raleigh, N. C., was announced in these columns May 16, was born in Morehead City, N. C., October 30, 1884. He began his telegraphic career in the city of his birth in 1906, and afterwards worked at New Bern, N. C. His advancement to the management at Raleigh, N. C., is a fitting recognition of his ability.

Mr. William Robert Edmondson, whose appointment as district commercial manager at Jackson, Miss., was noted in our issue of June 1, was born in Nashville, Tenn., January 9, 1883. He entered the telegraph service with the Louisville and Nashville Terminal Company at Nashville on December 6, 1898, and in November, 1907, he entered the employ of the Western Union Telegraph Company. Mr. Edmondson is well fitted for his position, and his selection was made on merit.

Mr. George Heldorfer, manager of the Western Union Telegraph office at Burlington, Iowa, has a record of 42 years of continuous service at that point, having entered the office in 1860 as messenger. In 1872 he was promoted to a clerkship and in 1875 became night press operator. Five years later he was transferred to the day service as operator and assistant manager, and in 1891 became manager, which position he still holds.

The Cable.

Mr. George G. Ward, vice-president and general manager of the Commercial Cable Company, New York, accompanied by Mrs. Ward, sailed for Europe on May 27 on the Steamer *Cedric*.

Mr. Robert Morrell, superintendent West India and Panama Telegraph Company, has returned to St. Thomas, B. W. I., after a tour of inspection covering all the company's stations in the West Indies and South America. While in Demerara Mr. Morrell contracted malarial fever and left for Europe on June 13 to recuperate.

Taxing Commercial Cable Company in Newfoundland.—The Supreme Court of Newfoundland has given judgment in favor of the Newfoundland government in its action against the Commercial Cable Company for $16,000 yearly as landing taxes. An appeal will be taken to the privy council.

An Extensive Cable Station at Far Rockaway.

A plot 100x200 feet, situated on Grandview Avenue, near Rue de St. Felix, at Far Rockaway, L. I., N. Y., has been purchased by the Postal Telegraph-Cable Company. The company proposes to erect extensive buildings on the property, to be used as a receiving and transmitting station for its transatlantic cable service. It is expected that a large number of the company's employes will be located at Far Rockaway.

Owing to the improvements and dredging being done at Norton's Point, Coney Island, the company has had to change its landing for ocean cables from that point and has located in Far Rockaway, which is about twenty miles distant from New York and situated directly on the Atlantic Coast.

The German-South American Cable Subsidy.—It is stated that the subsidy payable by the German Government to the German-South American Telegraph Company for the right of use of the company's cable to Brazil amounts to $322,000 per annum for the section between Borkum and Teneriffe, $220,500 for that between Teneriffe and Monrovia, and $210,000 for that between Monrovia and Pernambuco, the subsidy being for a period of forty years from the opening of each section. On the other hand, the company is entitled to 25 per cent. of the cable receipts, whilst the remaining 75 per cent. goes to the government, although only up to the amount of the total annual subsidies. The Imperial subsidy is calculated so that a surplus permitting of the payment of at least a minimum dividend of 6 per cent. remains after defraying all working and management expenses, interest and redemption charges on the bonds, and making allocations to the renewal and reserve funds.

The Telephone.

Mr. M. Ruberg, of the American Telephone & Telegraph Company of Philadelphia, was a recent New York visitor.

Telephone Literature in Foreign Languages.—The New York Telephone Company is canvassing for business in the Italian, Hungarian and Yiddish quarters in New York by postal cards printed in these three languages.

Change of Title.—The title of Mr. P. K. Baker, superintendent of traffic on the Southwestern Telegraph and Telephone Company, Dallas, Tex., has been changed to general commercial superintendent.

Telephony in Korea.—The government authorities in Korea are considering a scheme for the establishment of a long-distance telephone line between Seoul and Fasan, in addition to the existing telephone services between Seoul and Makan.

Telephone Conference.—Superintendents of the Cumberland Telephone and Telegraph Company from various cities met at Memphis, Tenn., May 23, and discussed matters pertaining to the business of the company. Louisville, New Orleans, Nashville, Knoxville and Evansville were represented at the meeting.

Farmer's Telephones in England.—Among the reforms which the postmaster-general of England proposes to introduce into the postal and telegraphic services this year is the extension of the telephone to farmers on the party-line system, at the rate of $15 per annum for unlimited calls within a restricted area, with a small charge for calls beyond that area. There will be five stations on each line.

Southern Telephone Traffic Chiefs in Conference.—The traffic department of the Southern Bell Telephone and Telegraph Company met in conference in Atlanta, Ga., May 23, and discussed problems affecting the service in that territory. The conference was largely attended by traffic superintendents, chiefs, etc., from seven southern states. The address of welcome was delivered by Mr. F. E. Montague, general traffic manager.

Telephone Rates in Europe.—The rate for unlimited telephone service is $49 in Antwerp and Brussels, $78 in Paris, $58 in Lyons, $20 to $44 in Germany, according to size of exchange; $39 to $58 in Italy, $25 to $28 in St. Petersburg, $37 to $41 in Moscow, $83 in London, and $23 to $81 in Austria, according to statistics recently collected by the British government on European telephone lines. Measured service is also supplied in many places.

Telephony in Cuba.—There are now over 6,000 telephones in use in Cuba and the business is rapidly increasing. The Cuban Telephone Company, which is financed with English and American capital, is now installing long distance lines on the island. Mr. W. H. Talbott is president of the company, which uses an automatic system. The company gives unlimited service, the rate depending upon the class of telephone required. An office telephone costs $84 per year and a residence instrument $60. The company is now installing 1,200 miles of pole line throughout the island, which, it is expected, will be completed in about two years. The poles are of various hard woods found in the island.

Cutting Down Toll-Call Delays.—The New England Telephone and Telegraph Company has introduced a new method of handling short-haul toll calls. Toll calls to points within fifteen miles of any exchange are now being handled by what is known as the "two-number no-delay method." This obviates the necessity of referring the call to the toll operator and the somewhat slow process of having her ask a lot of questions. Instead of calling for some particular person therefore, and being subjected to cross-examination by the toll recording operator, the caller must ask his local operator for the number he desires and then hold the receiver to his ear until the person at the other end responds. Wherever this new plan has been tried it has given great satisfaction, as connections are made in less than one-tenth the time of the old toll routine.

Telephone Decision by Interstate Commerce Commission.—The Interstate Commerce Commission at Washington on May 13 decided the first telephone case brought to it since Congress placed telephone companies as common carriers under the commission's jurisdiction. Mr. Wm. D. Shoemaker, of Drummond, Md., brought suit against the Chesapeake and Potomac Telephone Company because the charge demanded for his residence telephone was materially higher than paid for the same service by his neighbors who were old subscribers and had contracted with the company when it operated the now abandoned exchange at Drummond. The complainant maintained that the rate was unlawful and discriminatory, but the court held that contracts between old subscribers and the defendant, even though valid when made, cannot be accepted as now justifying different charges as between different subscribers similarly situated, such undue discrimination being forbidden by the act.

Reduction of Telephone Rates Ordered.

The New York Public Service Commission, second district, has ordered the New York Telephone Company to make the following reductions in telephone charges in New York City:

1. From the Borough of Manhattan below 110th Street to the Borough of Brooklyn, except Coney Island and Bath Beach, and from Manhattan below 110th Street to central station districts Astoria and Newtown on Long Island, from 10 cents to 5 cents.

2. From Manhattan below 110th Street to central station districts Flushing, Richmond Hill, and Jamaica on Long Island, from 15 cents to 10 cents.

Digitized by Google

Obituary.

Mr. E. C. Denham, age 45 years, assistant traffic chief of the Western Union Telegraph Company at Omaha, Neb., died on May 17.

Thomas Langdon, aged 68 years, a well-known old-time and military telegrapher, died at Minneapolis, Minn., May 14.

Col. Joe Hansen, an old-time and military telegrapher, and for many years president and superintendent of the St. Joseph Union Depot Company at St. Joseph, Mo., died at Hot Springs, Ark., May 24. Col. Hansen was a prominent citizen of St. Joseph.

Robert L. Sneed, aged 52 years, a well-known operator at Richmond, Va., died at Gordonsville, Va., on June 4. Deceased was one of the best known and most popular operators in the state and was admired and loved for his genial disposition and happy nature. At the time of his death he had been for several years the Associated Press operator for the Richmond *News-Leader*.

Thad. M. Schnell, aged 76 years, a well-known old time and military telegrapher, died at Des Moines, Iowa, May 30. He was born at Clearfield, Pa., in 1835, and learned telegraphy in 1851. With three brothers he entered the military telegraph service at the breaking out of the civil war and was stationed with the Army of the Potomac at various points. Mr. Schnell was employed in the Postal office at Des Moines for many years and recently wrote us that he was going to the hospital, but expected to be out in a few days. Three of the four brothers who were in the military service have died within the past few months.

Death of A. H. Inglee.

Albert H. Inglee, an old-time telegrapher, who was well known to many of the craft in all parts of the country, died in Ocala, Fla., on May 27. He was a native of Pembroke, Ont., and his first telegraphic service was in Montreal. Coming to the United States in 1878, his earliest engagement was with the Western Union Telegraph Company at Rochester, N. Y. Subsequent appointments found him located in New York, Washington, Cincinnati and Providence, from which latter place he returned to New York in the spring of 1890. Beside the Western Union, he had served the French Cable Company, the New York Associated Press, the United Press, the New England Press and the Associated Press. The state of his health led to the resignation of his position in New York early in 1910, and in March of that year he went to Florida in an endeavor to regain his strength. Finding that farming, in which he at first planned to engage, made too serious drafts upon his strength, he took a position as operator for the Western Union at Ocala. His death, which was sudden, was due to heart failure and nervous exhaustion

Memorial Services to General Fowler.—The annual memorial services in honor of the Fourteenth Regiment of Brooklyn, N. Y., well known during the Civil War as the "Fighting Fourteenth," and of General E. B. Fowler, were held at General Fowler's statue in Fort Greene Park, Brooklyn, Sunday, June 4. There was a large attendance. General Fowler was the father-in-law of Mr. W. H. Baker, vice-president of the American District Telegraph Company of New Jersey, New York, and was auditor of the Commercial Cable Company at the time of his death.

The Turner Monument Fund.

It is expected that ways and means will be devised by the Association of Railway Telegraph Superintendents at its Boston convention, June 26-30, to carry the Turner Monument project to completion. More than one-half of the necessary amount to defray the cost of the monument has been subscribed and the balance will no doubt be forthcoming.

In the work of keeping up the interest in the project and for the success which has attended the efforts so far, Mr. E. P. Griffith, chairman of the fund, deserves much credit. He has spent considerable time and thought on the matter, and has worked hard to make a success of the undertaking. He will have an interesting report to make to the Association at the Boston Convention on the work of the fund committee. This committee consists of E. P. Griffith, superintendent telegraph, Erie Railroad, Jersey City, N. J., chairman; Charles Selden, superintendent telegraph, Baltimore & Ohio Railroad, Baltimore, Md.; J. B. Taltavall, Telegraph and Telephone Age, New York; E. A. Chenery, superintendent telegraph, Missouri Pacific Railroad, St. Louis, Mo.; W. J. Camp, electrical engineer, Canadian Pacific Railway, Montreal, Canada; Col. W. B. Wilson, president Old Time Telegraphers' and Historical Association, Holmesburg, Philadelphia; F. J. Scherrer, secretary Old Time Telegraphers' and Historical Association, New York. All remittances should be made to Mr. J. B. Taltavall, Telegraph and Telephone Age, 253 Broadway, New York, who has been elected treasurer of the fund. All contributions are acknowledged in the columns of Telegraph and Telephone Age, and the funds deposited with the Washington Trust Company, New York, as soon as received.

Contributions received up to date are as follows: Previously acknowledged, $1,594.25; John W. Platten, New York, $10.00; C. F. Massey Company, Chicago, Ill., $2.00; Geo. M. Hughes, Monroe, N. Y., $1.00. Total, $1,607,25. Mr. Andrew Carnegie has promised a liberal contribution to the fund to be handed to the treasurer when the actual work of construction begins.

Municipal Electricians' Convention.

Mr. C. R. George, Houston, Tex., secretary of the International Association of Municipal Electricians, is busy with the arrangements for the convention of the association which will be held in St. Paul, Minn., September 12-15. He is securing some excellent papers to be read before the association, and there is every promise that the convention will be a most profitable and interesting one.

The Boston-Washington Underground Telephone Cable.*

BY B. GHERARDI, ENGINEER OF PLANT, AMERICAN TELEPHONE AND TELEGRAPH COMPANY, NEW YORK.

The project of having a complete underground conduit connection from Boston to Washington, and having therein a cable which would insure the service between these points against failure from storm damage, is one of President Vail's great ideas which is about to become a reality.

It is proposed to place in the conduit an underground cable, some of the circuits of which will be so efficient from a transmission standpoint that it will be possible to give telephone service between Washington and Boston over these underground conductors. This will be by all odds the longest telephone cable in the world.

This cable itself, and the conduits to provide for it, will represent a very large expenditure of money, and it is an indication of the broad policy which Mr. Vail is applying to the direction of the telephone business of this country that he is prepared to take such steps to insure the telephone service between Boston, New York, Philadelphia, Baltimore, Washington and the other points on the route of this cable against failure from storm damage.

The interesting feature of this cable, from an engineering standpoint, is that it is so constructed that practically all of the circuits in it may be phantomed and so that these phantom circuits as well as the side circuits, of which they are made up, can be loaded.

The loading problem on these cable circuits does not differ substantially from the problem of loading aerial phantom circuits which has already been described (see June 1 issue.) The difficult work in connection with the design and construction of the cable was to have the circuits sufficiently well balanced so that they could be loaded and phantomed without bringing in objectionable crosstalk.

The make-up of this cable is shown in the accompanying illustration. In the middle of the cable there are fourteen pairs of No. 10 B. & S. gauge conductors. Outside of these there are thirty-six pairs of No. 13 gauge conductors. In the spaces between the No. 13 gauge conductors and the No. 10 gauge conductors, six pairs of No. 13 gauge conductors have been put in because there was space for them. At the outside of the cable eighteen pairs of No. 16 gauge conductors have been placed because there was room for them. All of the No. 10 gauge pairs and the No. 13 gauge pairs, except the six put in between the tens are arranged so that they can be phantomed. That is to say, they are arranged in what we call a "quad formation." Each of these quads is built up by taking two twisted pairs and twisting them together, giving due attention to the length of twist employed on the pairs, and in twisting the pairs together. By this construction an arrangement is obtained which can be phantomed, providing certain necessary balances of capacity exist.

In connection with splicing up this cable, care must be exercised, not only to see that the wires are correctly jointed together, but at certain points tests are made to determine the capacity unbalance of the circuits in two directions, and at these splices to so associate the wires and pairs as to have these unbalances in opposite directions, that is, so that they will tend to neutralize each other.

These precautions are necessary because the transmission efficiency of the cable is so great that crosstalk taking place at a considerable distance from either of the stations at the ends of the cable would be much more audible than in circuits of lower transmission efficiency.

The loading coils are spaced at intervals of about 1.4 miles, the side circuit coils and phantom coils being placed at the same point. This spacing is determined by the capacity of the conductors, the side circuits having a mutual capacity of about .070 mf. per mile and the phantom having a mutual capacity of about .1 mf. per mile.

The transmission efficiency of these circuits is interesting, and in this connection I may say that

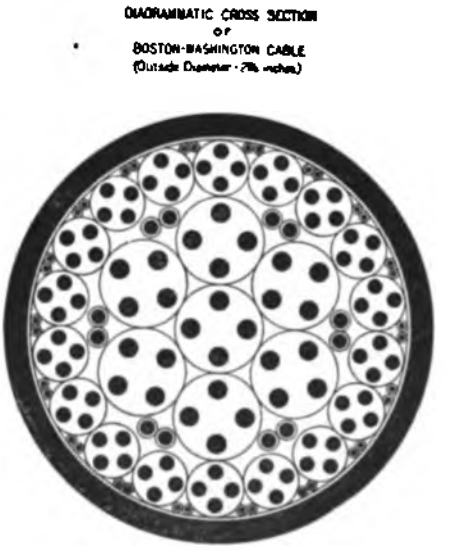

DIAGRAM SHOWING ARRANGEMENT OF CONDUCTORS IN BOSTON-WASHINGTON UNDERGROUND CABLE.

while a sufficient amount of this cable has not as yet been manufactured to permit of actual transmission tests on it, so great is our confidence in formulæ for computing these efficiencies which have been developed as a result of our studies and experiments that we are satisfied that the results predicted will be obtained, and the manufacture of about 150 miles of this cable at a cost, including loading of about $1,000,000, has been recommended with complete confidence in regard to the results.

The distance from New York to Washington is 235 miles. The most efficient circuits in this cable will be the No. 10 phantoms. These will have a transmission efficiency equivalent to only thirteen miles of standard cable. That is, they are nearly

* Extracts from paper read before the New York Telephone Society, April 18.

Digitized by Google

twenty times as good as standard cable and decidedly better than unloaded aerial No. 12's. The physical No. 10 circuits will have a transmission efficiency between New York and Washington of sixteen miles of standard cable. The phantomed thirteens twenty-one and a half miles of standard cable and the physical thirteens twenty-eight and a half miles of standard cable. These last circuits would not give good service from all subscribers in Manhattan to all subscribers in Washington. They will, however, be very useful from New York to Philadelphia, Wilmington and even Baltimore, and for other combinations such as Philadelphia and Washington. Between Boston and Washington the only circuits that can be counted on for commercial service will be the phantomed No. 10's. These will give a transmission efficiency between test boards of twenty-six miles. This will be sufficient to insure the service in case the open wire lines are down, although it is not expected that they will have to be used in this way, because it is not likely that there will be so many breaks in the lines that the cable would have to be used at any time all the way from Boston to Washington. All open wire lines are not likely to be down at the same time both north and south of New York City. The cable intersects the open wire lines at numerous points between these two places so that patches can be made at short intervals.

QUESTIONS TO BE ANSWERED.

[The success which has attended our plan of publishing in each issue a list of questions covering the subjects considered in Jones' Diagrams, has encouraged us to maintain the work through other books. Students of telegraphy throughout the country are finding these questions of great assistance in their studies of the general principles underlying the operation of the apparatus with which they come in daily contact. Many consider this the best plan which has yet been devised for a systematic study of the technical side of the telegraph. Having completely covered Mr. Jones' book we are now covering "The Quadruplex," by Maver and Davis, and will bring out, in a like manner, all the facts that every telegrapher should know about duplex and quadruplex telegraphy as found in this book.]

CHAPTER III.

What is the function of the transmitter used in the Stearns duplex?

How many wires are wound around the magnet cores of the relays used in duplexes and quadruplexes?

How are they wound, and why are they so wound?

If the two wires around a relay core are of equal length and resistance, what is the magnetic effect upon the relay when an electric current is applied at the home station?

What is the effect upon the relay when a battery is applied at the distant end?

What is the object of the multiplex systems of telegraphy?

How is one wire used to do the work of two by means of a duplex and of four with a quadruplex?

What is the rheostat used for?

Can a rheostat be adjusted to balance the resistance of a wire?

Is it necessary that a wire should have a given resistance in order to work it duplex or quadruplex?

Why does one wire of larger diameter than another carry more current?

What is the effect upon the current of using wires of larger resistance?

In order to balance the resistance of a line-wire by the use of a rheostat must the size and length of the wire in the rheostat be the same as that of the line-wire?

What kind of wire is used in the construction of the rheostat?

Why is fine german silver wire employed for rheostat coils?

Study the method, from Fig. 15, of connecting the german silver coils of the rheostat with the brass discs on the top of the box.

How are the german silver coils wound?

Why are they so wound?

State the law bearing upon this point of construction?

If we have a wire of say 3,000 ohms resistance, how can we balance it on the rheostat?

What is the effect of wet weather upon the line resistance?

How is the resistance in the rheostat altered to meet such changes in the line resistance?

Why is it necessary to preserve a balance between the line wire and the rheostat?

How is the resistance of the rheostat coils indicated?

In the construction of condensers what electrical law is involved?

If we electrify a conductor with electricity of one polarity, what is the effect upon surrounding objects?

What is the name of such action?

Are all substances equally susceptible to inductive influence?

Can inductive effect be prevented by screening?

What medium possesses the lowest inductive capacity?

What substance has the highest inductive capacity?

How is the practical condenser constructed?

How are the sheets of tinfoil connected and how are they separated from one another?

Referring to Fig. 17, what is the effect of charging one set of the plates by contact with the line wire?

How is the capacity of a condenser varied? Study the construction of a condenser, as illustrated in Fig. 18.

Telegraphy in Siberia.—A bill has been submitted to the Russian Duma providing for improved telegraphic communication between western Siberia and western Europe and contemplating the erection of four wireless telegraph stations on the shores of the Kara and White Seas.

ADDRESS ALL COMMUNICATIONS TO
J. B. TALTAVALL, - Editor and Publisher
253 BROADWAY, NEW YORK.
T. R. TALTAVALL, Associate Editor.

CABLE ADDRESS: "Telegage," New York.
Telephone: 6657 Barclay

CHANGES OF ADDRESS.—In ordering a change of address the old as well as the new address must be given.
REMITTANCES to Telegraph and Telephone Age should be made invariably by draft on New York, postal or express money-order, and never by cash loosely enclosed in an envelope. By the latter method money is liable to be lost, and if so remitted is at the risk of the sender.

June 16, 1911.

The Book Department of Telegraph and Telephone Age has always been a prominent and carefully conducted feature of this journal. The desire has been and is to furnish our readers and buyers everywhere the readiest means possible of securing such technical books as they may require. Aiding buyers in their selection with advance information, which at all times is cheerfully furnished; promptness in sending books, filling all orders on the same day of their receipt, has brought to this department a generous clientage. Catalogues fully covering the range of books treating on the telegraph, wireless telegraphy, the telephone, as well as those on the general subject of electricity, together with the principal cable codes, will be sent to any one asking for the same.

Railway Telephone and Telegraph.

It is never safe to assume that what cannot be done today cannot be done tomorrow; our knowledge of today is not so ripe as that of tomorrow. This truism was never more exemplified than in the adoption of the telephone to train dispatching. It is only a very few years ago that railway officials looked upon the proposal to substitute the telephone for the telegraph in railway operation as a risky, if not dangerous experiment. Their fears were not grounded upon facts, however. The practicability of such use of the telephone had not at that time been demonstrated and they argued from their experience with it at that day which was very limited indeed. The fact is few people knew how to use the telephone even in those days and had no idea of its possibilities. It was known that the instrument would not carry certain sounds and that other sounds were so much alike that the telephone could not be relied upon as a means for directing the movements of trains. Since then, however, experience has taught us to use it properly and get the best results out of it. The fault was not with the instrument, but was due to the lack of knowledge on the part of the users of it.

Now things are all changed. The possibilities of the telephone are better understood and experimentation and experience have proved its flexibility and adaptability to many uses. The result of these investigations is shown in the wide and extending employment of the telephone in train dispatching, and it is not rash to predict that it will eventually supersede the telegraph entirely in this class of work.

The railway telegraph service has generally been placed at a disadvantage in its relation to railway management. All railway officials admit that it is an actual necessity in modern railway operation, yet they have as a rule regarded it as an unproductive service in a money sense. It was never intended to make money directly for the companies, but it does indirectly make money for them by helping to save it and by the conveniences it affords the managers in the transaction of business. The time element comes in here. The telegraph, first of all, saves time, and time, above all else, is equivalent to money to a railroad. Every use of the telegraph for legitimate railroad business means, in one way or another, an increase in the company's revenues. It may not be apparent to the ordinary observer, but an analysis of each transaction of this character will generally lead to this conclusion.

We have spoken here of the telegraph particularly because it was toward the telegraph that the attitude referred to was assumed. The telephone coming as it did, many years later, has generally been looked upon with more favor. But whatever feeling in regard to the telegraph ever existed has all disappeared, and every railroad manager now regards it as essential to the transaction of railway business as any other part of the company's operating equipment.

Is the Change of Title of Railway Telegraph Superintendent Imminent?

Is the superintendent of a railway telegraph system an official reality if there is no telegraph to superintend? The telephone has entirely superseded the telegraph on some roads, and will do so on many others; therefore, the title of superintendent of telegraph certainly is and will be a misnomer. To describe the duties of these officials their titles will have to be revised and brought up to date. "Superintendent of telephone," or an equivalent seems to be the only logical solution of the problem.

General Electric-Westinghouse Pool Dissolved.—It is stated that the General Electric Company and the Westinghouse Electric and Manufacturing Company have canceled their fifteen-year patent pool agreement.

Governor Wilson on Corporations.

In a recent address on "Corporations," before the University of California, Governor Wilson of New Jersey said in part: "We are no longer afraid of our corporations as we used to be, because we are beginning to understand just what they are, and, to some extent, at any rate, just how they can be controlled and made to serve the purposes of our life without governing and controlling us. There was a time when our feeling about them was almost one of panic. We had undoubtedly ourselves created them. There was no disputing the fact that they were our creatures, made by laws which we ourselves had enacted, and had supposed we understood; but we stood amazed at the work of our own hands, and not only amazed, but awed and frightened. It is not a little amusing, as we look back upon our one-time state of mind in this matter, because, having created the corporations, we can certainly alter them if we please, and control them in any way that we choose. They are not actual persons. We made them—God did not—and we can alter the work of our own hands as we will."

In referring to public service corporations, Governor Wilson said: "Public service corporations, such as railroads, street railways, gas companies and companies which supply electric light and power, are in a still larger sense public instrumentalities. Besides having the artificial advantages and powers conferred upon the ordinary corporation doing what we call private business they are in partnership with the government in the laying of rails, the erection of poles and wires and the laying of conduits as the means of transmitting their service. They have had delegated to them the government's right of eminent domain, the right to make partial use of public highways, to condemn rights of way across pieces of private property.

"Moreover, they are in a very interesting sense natural monopolies. They generally use the pieces of land and the roads and highways which are most convenient to their purposes, and most direct for effecting the communication which they wish to effect; and it is perfectly obvious that if other companies are allowed to compete with them, there is a very wasteful duplication in outlay and equipment. So that competition generally results in an eventual combination of the competing companies and the necessity to charge a price on what they supply that will pay the interest on twice as great an investment as was really necessary for the service."

"The real difficulty in the management of our corporations in recent years," he said, "has been the wrong point of view of those who were in control of them. They did not recognize that they were public trustees. They acted as if they were conducting their own private business. Let them change their point of view, and there is no problem to solve. There is no legislation necessary if they will only regard themselves as trustees of the common interest, bound by considerations not private, but public, in the conduct of their business.

"I think that the spirit of the age is slowly changing," Governor Wilson said in conclusion. "The time of contest and vituperation and mutual abuse and misunderstanding is passing away. It is beginning to be recognized that those who are leading the reform movement of the age are leading it in all sincerity and genuine public spirit."

Highway Crossing Bell Signals in Canada.

Following are the specifications for electric bell signals at highway railway crossings as issued by the Board of Railway Commissioners of Canada:

POST.—The bell must be placed upon a post of some suitable structural material. If the post is made of wood, it must be of sound timber not less than 8 by 8 ins. and 18 ft. long, and shall be firmly set in the ground to a depth of 4 ft. If it is made of iron or steel, it shall be not less than 4 ins. in diameter, shall extend 14 ft. above the ground, and shall be firmly bolted to a concrete or other foundation constructed below the frost line. If other suitable structural material is used it must be of the length mentioned above, and of sufficient strength to carry the weight placed upon it.

BELL.—The bell shall be either of the locomotive type, the gong type, or the twin-gong type, and it must in each case emit a clear, loud volume of sound under all weather conditions. If the locomotive type is used the bell shall be of standard size (about 18 ins. in diameter); if the gong type is used, the gong shall be at least 12 ins. in diameter; and, if the twin-gong type is used, the gongs shall be at least 10 ins. in diameter.

SIGN.—A sign shall be placed upon the same post as the bell, with the word "danger" upon it in letters of not less than 6 ins. in length, to be illuminated either by direct or reflected light so as to be plainly visible after sunset. There may be added to the post, if so desired, the railway crossing sign provided for by sec. 243 of the Railway Act.

OPERATION.—The bell and the illumination of the sign shall be controlled and operated electrically and automatically by the approach of trains, in such manner that only approaching trains shall operate the signal, and the signal must remain in operation until the rear end of each approaching train has passed the crossing. The bell and lamps used for illumination may be operated from any suitable source of electric current that is continually available, or from batteries. If batteries are used they must be either chemical batteries of the caustic potash type, having a capacity of not less than 300 to 400 ampere hours, or storage batteries of the same capacity.

Mr. Carnegie Promoter of Peace.—The *Christian Advocate* of May 25 publishes an editorial on Mr. Andrew Carnegie in connection with the unveiling of the bronze tablet on April 28 at Pittsburg in memory of the forty-three volunteers from Alleghany County, Pa., who served in the United States Military Telegraph Corps during the Civil War. It refers to Mr. Carnegie as a philanthropist and an enthusiastic promoter of peace.

The Boston Meeting of the Association of Railway Telegraph Superintendents.

The act of one man fifty years ago set in operation forces which find expression in the Association of Railway Telegraph Superintendents. When Charles Minot, superintendent of the Erie Railroad, in the fall of 1851 sent the first telegraph train order, he nor any of his contemporaries realized the importance of this bold step nor had they the faintest idea as to what it would develop. Mr. Minot himself was confident of the result of his experiment, but his associates looked upon it with many misgivings. The greater mind, however, dominated and Mr. Minot carried the day and opened the way for the development of what is now one of the most important departments of railway operation—the control of the movements of trains by telegraph or telephone.

I. T. DYER,
Of Los Angeles, President.

J. B. SHELDON,
Of Omaha; First Vice-president.

To trace the development of train dispatching by telegraph since the first telegraph train order was sent, would be a difficult task; it is sufficient for our purpose to look at the results. Railroad managers are ready to adopt anything that will yield results. The telephone has taken its place in railway operation, and it has proved to be such an advance that it is rapidly displacing the telegraph. This brings up the question of the official title of the men who manage the telegraph-telephone department of the railroads. There is at least one large railroad that has substituted the telephone for the telegraph over its entire system. Is the head of the department superintendent of telegraph or superintendent of telephone? The members of the association will probably be confronted sooner or later with this question and although it need not be a difficult one to settle, it might be given thought in the meantime.

P. W. DREW,
Of Chicago; Secretary-Treasurer.

C. SELDEN,
Of Baltimore; Chairman Eastern Division.

The operation of railways by telegraph or telephone has called for the use of many modern electrical inventions, such as electric generators, electric motors, storage batteries, etc., but these after

Digitized by Google

all are mere machines. The real achievements originate in the human brain. Without the application of thought the machines could not act, indeed they would not exist. So after all, it is not the machine that deserves our admiration, but the brains that conceived it.

The Association of Railway Telegraph Superintendents has grown to be one of the most important

E. A. CHENERY,
Of St. Louis; Chairman Western Division.

arms of the railway service, and will become more so as time goes on, since by the use of the telegraph or telephone the consumption of time is reduced almost to the vanishing point.

The Association's annual meetings are very profitable to the members and the railroads they represent, for they afford the opportunity for each

W. C. WALSTRUM,
of Roanoke, Va.; Chairman Topics Committee.

one to learn what the others are doing in the line of progress. To be widely informed the railway telegraph superintendent must necessarily move about in his own bailiwick and observe things, and do the same, as far as possible, with reference to other lines. But to keep in touch with the work of others undoubtedly would require too much time and labor, hence the necessity of an organization which will bring all superintendents together at a prearranged time and place for the exchange of ideas and experiences for mutual good. It is therefore the duty of every member to add to

G. A. CELLAR,
Of Pittsburg; Chairman Committee on High-Tension Wire Crossings.

the fund of general knowledge as far as he can, and thus get the best out of these periodical gatherings.

The Association of Railway Telegraph Superintendents is accomplishing excellent work and aiding very materially in the upbuilding of the rail-

W. F. WILLIAMS,
Of Portsmouth, Va.; Chairman Committee on Miscellaneous Matters.

road service of this country. The association has made its impression on the railway world and has acquired a standing among professional bodies that the members may be proud of.

The Hotel Brunswick, which will be the headquarters of the Association of Railway Telegraph Superintendents during the Boston convention, is one of the most popular hotels in that city. It is located on Boylston Street and is within two blocks

HOTEL BRUNSWICK,
Boston, Mass., Convention Headquarters.

of the New York, New Haven and Hartford and the Boston and Albany Railroad stations. It is directly opposite the Massachusetts Institute of Technology and Copley Square, and is convenient to the principal points of interest in the city. No less than fifteen different electric car lines pass the

E. P. GRIFFITH,
Of New York; Chairman Committee on Form for Delivery of Messages on Trains, etc., and Chairman of the Turner Monument Committee.

door of the hotel, enabling the guests to reach any part of the city and suburbs. The Brunswick is conducted on the American and European plans, and is modern in all respects.

HISTORY OF THE ASSOCIATION.

It may be of interest to many to trace in brief the history of this organization from its inception at Chicago, November 20, 1882. At this first meeting the officers elected were: W. K. Morley, president; William Kline, vice-president, and C. S. Jones, secretary and treasurer.

W. W. RYDER,
Of Chicago; Chairman Committee on Resolutions.

At the second meeting also held in Chicago, June 13 and 14, 1883, the interest in the new organization was shown by the fact that there were thirty railroads represented. Mr. Morley was again elected president; Charles Selden, vice-president, and P. W. Drew, secretary and treasurer. Mr. Drew has filled this position with credit to himself and the association ever since that time being re-elected at each recurring meeting of the association.

At the third meeting held September 17, 1884, in Philadelphia, Charles Selden was elevated to the presidency, and E. C. Bradley was elected vice-president. The fourth meeting at Cleveland, Ohio, June 17 and 18, 1885, chose C. W. Hammond to succeed Mr. Selden, and elected as vice-president, George L. Lang.

The dates of the fifth meeting, which was held in St. Paul, Minn., were June 16, 17 and 18, 1886. At this meeting thirty-four railroads were represented, and the social feature of these conventions came into prominence, the guests being entertained by an excursion to Duluth and the Apostle Islands by rail and boat. A. R. Swift was elected president, and George L. Lang was re-elected vice-president.

The East claimed the sixth convention, which was held at Boston, July 13 and 14, 1887. It was at this meeting that the practice of showing exhibits of telegraphic and other electrical devices was first introduced. George L. Lang was here elevated to the presidency, and G. C. Kinsman was elected vice-president.

Digitized by Google

New York was the scene of the seventh meeting which met July 11, 1888. Edison's phonoplex system was shown in operation at this time and Mr. Kinsman was made president, C. A. Darlton succeeding him as vice-president.

Washington, D. C., entertained the eighth annual convention, which met October 16 and 17, 1889. Benjamin Harrison, who was then president, received the members of the convention in the White House. C. A. Darlton being elected to the presidency, George T. Williams was elected vice-president to succeed him.

The ninth annual gathering assembled at Niagara Falls, June 18 and 19, 1890. This convention was notable for the large number of papers read and the exhibition of the long distance telephone by which conversation was held with parties in Albany and New York. George T. Williams was elected to the presidency and George M. Dugan was elected vice-president.

At the tenth annual convention held at Cincinnati, Ohio, June 17 and 18, 1891, the number of railroads represented had increased to thirty-seven. This meeting elected C. S. Jones as president and L. H. Korty vice-president.

The eleventh in the series of conventions assembled at Denver, June 15 and 16, 1892. This meeting was largely attended, and was made notable by a paper by Thomas A. Edison. L. H. Korty being advanced to the presidency, U. J. Fry was elected to succeed him as vice-president.

The twelfth on the list convened at Milwaukee, June 20 and 21, 1893. The World's Fair at Chicago being then in progress, most of the members included a visit to this great exposition in their convention trip. U. J. Fry was elected president and O. C. Greene vice-president.

On June 13 and 14, 1894, the thirteenth annual convention met at Detroit. Following the usual custom, at this convention O. C. Greene was made president, and E. R. Adams was elected vice-president.

At the fourteenth annual convention held in Montreal, June 12, 1895, M. B. Leonard was elected president, and J. W. Fortune vice-president.

Old Point Comfort, Va., was the scene of the fifteenth convention which met June 17 and 18, 1896. Among other papers presented at this meeting was one by W. W. Ryder upon "The Telephone in Railway Practice." G. M. Dugan was elected president and J. W. Lattig, vice-president.

For the second time Niagara Falls was chosen as the place of gathering, the sixteenth annual convention meeting there June 16, 1897. J. W. Lattig being made president, W. W. Ryder was elected vice-president.

The most notable feature of the seventeenth annual convention which met June 15, 1898, at Omaha, Neb., was the report of a special committee upon low resistance relay experiments. W. W. Ryder was elected president and L. B. Foley, vice-president.

For a meeting place for the eighteenth annual convention the superintenderts turned toward the South, gathering at Wilmington, N. C., May 17 and 18, 1899. L. B. Foley being elected to the presidency, W. F. Williams succeeded him as vice-president.

Detroit was then for the second time chosen as the convention city, the nineteenth annual convention meeting there June 20, 21 and 22, 1900. W. F. Williams was naturally elected to the presidency, and C. F. Annett was elected vice-president.

Buffalo was the scene of the twentieth annual convention which met in that city, June 19, 20 and 21, 1901. C. F. Annett being made president, F. P. Valentine was elected vice-president. This being the year of the Pan-American Exposition, an unusually large number were in attendance at this meeting.

For the third time Chicago became the scene of the convention, the twenty-first annual meeting being held there June 18, 19 and 20, 1902. Among the important subjects which came up for discussion at this convention were the questions of typewritten train orders and the use of the telephone in connection with railroad operation. J. H. Jacoby was elected president and W. J. Holton, vice-president.

The far South claimed the twenty-second annual convention, which met in New Orleans, May 13, 14 and 15, 1903. The use of the telephone in connection with railway work again took a large part in the discussion. Mr. F. F. Fowle, of the engineering department of the American Telephone and Telegraph Company, presenting a lengthy illustrated paper upon "The Transposition of Telephone Lines to Prevent Cross Talk and Induction." At this time C. S. Rhoads was honored with the presidency and C. P. Adams became vice-president.

Indianapolis was the scene of the twenty-third convention in the series, which met in that city June 15 and 16, 1904. After the adjournment a side trip was made to the St. Louis Exposition. Henry C. Hope was elected president at this time and E. E. Torrey, vice-president.

The twenty-fourth annual convention met at Chattanooga, Tenn., May 17 and 18, 1905. The increasing use of high-tension transmission made very timely the paper of W. J. Camp upon "High Tension Wires on Railway Right of Way," which he presented at this meeting. E. E. Torrey was advanced to the presidency, and E. A. Chenery was elected vice-president.

The superintendents again turned their faces toward Denver, the twenty-fifth annual convention meeting there June 20 and 21, 1906. The question of high-tension wires again came up and occupied a large place in the discussion. E. A. Chenery was elected to the presidency and E. P. Griffith was elected vice-president.

Atlantic City, N. J., the popular waterside resort, entertained the twenty-sixth annual convention, which met June 19, 20 and 21, 1907. An unusually large number of interesting papers were read at this meeting, and some most interesting discussions developed. E. P. Griffith was advanced to the presidency and W. J. Camp succeeded him as vice-president.

Digitized by Google

The twenty-seventh annual convention met in Montreal June 24, 25 and 26, 1908. W. J. Camp was elected president and G. W. Dailey vice-president. Upon Mr. Dailey's promotion from the position of telegraph superintendent of the Chicago and Northwestern to the superintendency of the Wisconsin division of that road, J. B. Fisher was elected by the executive committee as vice-president.

The 1909 convention was held at Detroit June 23, 24 and 25, with about seventy-five active members present. J. L. Davis of Chicago was selected

S. A. D. FORRISTALL,
Of Boston; Chairman Entertainment Committee.

to head the organization for the ensuing year and Los Angeles was selected as the place of meeting for the 1910 convention.

The twenty-ninth annual convention met at Los Angeles, Cal., June 20-24, 1910, and notwithstanding the great distance for most of the members to travel, there was a large and enthusiastic attendance. Isaac T. Dyer of Los Angeles, Cal., was elected president. At this meeting the movement to erect a monument at Turner, N. Y., to commemorate the sending of the first telegraph train order (in 1851) was officially sanctioned and a committee appointed to carry the proposition into effect.

Growth of Telephone Train Dispatching.

In every issue for some time past we have recorded the introduction or extension of the telephone train dispatching system on one or more railroads in this country and in Canada, attesting to the superiority of the telephone over the telegraph for this class of service. The experimental stage in this application of the telephone has long since passed and the practice has become standardized.

We publish in this issue a table showing the status of the telephone in railway train dispatching operation in the United States and Canada, and the most interesting thing about it is the great increase shown over last year's statistics of the number of miles of road controlled by the telephone dispatching system. Some railroads did not report but these are few compared with the total number, so the results are reasonably accurate. The statistics show that at the time the table was compiled, June 1, there were 40,160 miles of track controlled by railway telephone dispatching, while in the year previous the number of miles was 24,831, showing an increase in one year of 15,329 miles, or slightly over 60 per cent.

The record is indeed a remarkable one and shows the keen interest taken by railroad managers in new things of merit. It is reasonable to assume that every mile of the railroads in this country now using the telegraph will eventually be equipped with the telephone system in a very few years, now that its advantages have been demonstrated beyond question.

ANSWERS TO QUESTIONS.

[In this department questions on matters of a practical character, and of general interest, will be answered. Questions intended for this department must be signed by the writer's full name—not for publication, but for identity. No attention will be paid to anonymous communications.]

45. Q. Can you inform me what is the standard wave length adopted by the United States Navy for ship wireless telegraph installation? W. T. I.

A. Four hundred and twenty-five meters.

46. Q. Will you please explain the process of charging storage batteries and how to take care of them in order to get the best service out of them? F.

A. The information desired would require more space than we can give up to it in this column. We refer our correspondent to any standard work on storage batteries for complete information. "Storage Batteries, Their Theory, Construction and Use," by A. E. Watson, is an excellent book on the subject. It is written in very clear and simple language and covers the subject very thoroughly. This book can be obtained of Telegraph and Telephone Age at $1.50 per copy.

Telephone Train Dispatching on Pittsburg and Lake Erie Railroad.—The Pittsburg and Lake Erie Railroad will equip two circuits with fifteen telephone selectors and the necessary telephones and auxiliary apparatus. One circuit, equipped for eight stations, will be put in between McKeesport and Brownsville, Pa., a distance of forty miles. The other, equipped for seven stations, will be installed between McKeesport and Connellsville, Pa., a distance of forty-three miles, Western Electric apparatus being used. The dispatcher for both circuits will be located at McKeesport. Mr. L. A. Lee, Pittsburg, Pa., is superintendent of telegraph.

Artistic Office Front at Seattle.

The accompanying illustration shows an exterior view of the Western Union main office at Seattle, Wash., and was made from a photograph taken at midnight recently. The feature is the magnificent marquee awning, which, when lighted at night, gives a very handsome and artistic effect. The rays reflecting upon the plate glass window, make the surroundings as bright as by day. The marquee is nine feet wide by sixteen feet long, by twenty inches deep and is constructed of heavy angle steel and galvanized sheet iron.

The roof is heavy fireproof glass laid on steel beams. The background of the sign is of double-strength, dark blue flash-glass sand blasted on one side and inlaid with ten-inch letters of white opalescent glass and is illuminated with fifty twenty-five-watt tungsten lamps on the inside. The white letters and blue background make a very brilliant and contrasty day sign of the Western Union standard sign colors.

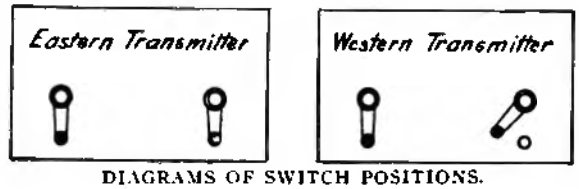
At night the rich glow from the marquee lights gives the exterior and front office a cheerful and inviting appearance. Experts in marquee construction state that this is the most effective and artistically illuminated marquee in the Northwest.

ARTISTIC FRONT OF WESTERN UNION TELEGRAPH OFFICE, SEATTLE, WASH.

Testing Repeater Points.

BY J. B. DILLON, DALLAS, TEX.

On page 319 of the May 1 issue of TELEGRAPH AND TELEPHONE AGE, Mr. J. B. Slocum, night chief operator of the Postal Telegraph-Cable Company at Buffalo, N. Y., shows an arrangement to test the main line points of a Weiny-Phillips repeater. The accompanying diagram shows how the same test may be applied to the Atkinson and Milliken repeaters. The illustration shows the connections when the Western side is being operated. If the Eastern side is the one in operation then of course the positions of the switches must be reversed.



DIAGRAMS OF SWITCH POSITIONS.

In this connection it might not be amiss to state that while this quick test shows whether the main line points are breaking, it does not indicate how the signals are passing. To ascertain this fact we must cut in at the main switch-

Digitized by Google

board, for the reason that in wet weather it is necessary to increase the spring tension on repeater relays. In consequence of this the tests would not permit of the opposite relay responding in tone to the opposite points because of this high adjustment. The main switchboard relay can be adjusted to meet the conditions without disarranging the repeater relay adjustment.

Hence I would not recommend the test in any but dry weather when both relays are working on a normal adjustment.

Railroad Telephony.

Mr. Gregory Brown read a paper on "Some Recent Developments in Railroad Telephony" at the Pacific Coast meeting in Los Angeles, Cal., of the American Institute of Electrical Engineers.

Mr. Brown reviewed the progress of train dispatching by telegraph which has been in vogue about sixty years, and has on the whole given quite excellent results. A few years ago the passage of the nine-hour telegraphers' law made it imperative for the railroads to reconsider the matter of dispatching in all its branches. It was at this time that the first extensive attempts to use the telephone for this service were made and less than four years ago the first telephone dispatching line using modern equipment was installed in New York. The telegraph has performed three main classes of service for the railroads. First, train dispatching; second, message service; third, block-wire service. While the first of these is most important, the attempt to use the telephone for railroad purposes involves the need of its meeting the other classes of service also.

In the dispatching work three requirements are apparent. One, ability to signal any one of fifty or more stations on a 250-mile line and ability to signal the dispatcher from any one of these stations; two, arrangements whereby any number of stations can simultaneously listen in; third, means for quickly testing and patching any portion of the circuit which gets into trouble. These requirements the telephone has met completely. Moreover, its great flexibility has made it possible so that officials who are not telegraph operators, but who are interested in the movement of railroad traffic, can listen on the wire and keep in touch with traffic conditions; it has also permitted the signaling of stations without interrupting conversation; it also gives automatic notification to the dispatcher that the station which he is calling is actually receiving the signal.

Mr. Brown described at some length the three types of selectors which are used for calling any particular station. These are: instruments responding only to a number and duration of long and short current impulses, or long and short intervals between impulses; instruments arranged to be installed simultaneously and to operate independently but in synchronism with each other by means of local energy at the station; instruments of the step-by-step type which are stepped around in synchronism by a succession of impulses from the dispatcher's office, the number of these impulses determining the station called. The Gill selector is an instrument of the first or code-impulse type. The Wray-Cummings selector is one of the second type and the new Western Electric selector is one of the third type.

The telephone has completely provided the message service that is necessary in railroad work. The message wires are also used for sending out time to the stations and towers, the method having been developed to do this with entire reliability. Block service has also been provided for communication between two adjacent block towers. Telephones are also used extensively at railroad sidings and enable train crews to get in touch immediately with the dispatcher. Portable telephones have come into use on trains, some railroads providing a portable set for each train with a line pole so that connection can be made with the line in case of accident or delay.

How Mr. Sprague Left Mr. Edison's Employment.

Mr. Frank J. Sprague, the well-known electrical engineer and inventor, of New York, has been presented by the American Institute of Electrical Engineers with the Edison medal for meritorious achievement in electrical engineering. Mr. Thomas A. Edison was a special guest.

In accepting the medal Mr. Sprague reviewed his work in electrical engineering, and referred to his association with Mr. Edison, having left the navy to enter the employ of Mr. Edison as assistant. He recalled the surprise, when in 1883 he reported for duty to Mr. Edison, with which the news was received that Mr. E. H. Johnson had promised him the munificent salary of $2,500, the manner of Mr. Edison betokening a doubt as to his earning capacity.

After a period of activity in connection with the earlier central stations, a request that he should leave the construction department in order to undertake some calculations in relation to the transmission of power, which would have led to an interruption in lines of work in which his interest was increasing, caused him to enter a protest with Mr. Edison, to which the following reply was received: "Sprague: As the construction department is about to be given up, I think the better plan would be for you to resign. Edison." Mr. Sprague said that he did resign and that this is the real reason why he is the recipient of the Edison medal. "No man," he said, "who thinks that he has within himself the capacity for a reasonable share of independent development, and who wishes to carve out his own career, can ever remain the agent of any one, and surely not the subordinate of a man of such intense activities and of so dominating a personality as that of the great inventor who has left such an imprint upon his age and whom all delight to honor."

Easy Tests for Trouble on Railway Telephone Lines.*

BY J. A. KICK,
SUPERINTENDENT OF INSTALLATION, NEW YORK CENTRAL LINES WEST OF BUFFALO, CHICAGO.

The all-important circuit in railway service is the dispatcher's circuit. It commands first attention in all maintenance work.

Telephone dispatching equipment is divided into two classes, "Transmission" and "Signaling," either or both of which may be partially or totally interrupted, depending upon the nature and location of troubles. Failures in one class of equipment may or may not cause partial or total failure in the other.

A ground on one side of a metallic signaling system will not interrupt the signaling, but may produce sufficient noise to drown the transmission. To locate such ground troubles, ring to call in the test stations, and by opening the line switch locate the trouble between two test stations. Then ring in the intermediate stations and have each momentarily open the cut-out switch (a switch which clears the line of all office equipment). If the opening of the switch does not clear the trouble, have the station put a "short" across the line for a listening test.

If the opening of any cut-out switch removes the trouble have the attendant clean the arrester, or remove the carbons, and then close the switch for test.

Should the ground be between stations the listening test will quickly show between what points to look.

Linemen with test sets can call in between stations and give the wire chief a "short" for a listening test, report clearing trouble, get clearances with further instructions, and in general get and give much assistance.

It is well to keep in mind the fact that a "short" near the trouble, even though the "short" be on the far side from the wire chief, will so nearly balance the line as to be deceptive. The longer the line between the wire chief and the point of test the more careful the wire chief must be to avoid being deceived by tests at points near the trouble.

To illustrate: A ground on one side of a telephone circuit causes noise, because induced current is afforded a path to ground direct from one wire of the pair, and indirectly from the other through the bridges. That is, an unbalanced static condition is produced.

If the equipment can be stripped from the line, and a "short" placed on the circuit at some point beyond the ground trouble, a bridge measurement will very effectively locate the trouble. But it is not always possible to accomplish this, and for practical purposes a location between two stations will be satisfactory.

An open wire will totally interrupt the selective signaling to stations beyond the open, and may so change the current values on the line between the main office and the open as to cause a failure of these selectors.

In cases where an "open" of one line wire does not interrupt the signaling between the main office and the "open," a general idea of the location can be quickly secured by ringing each station and observing the last station on the line that can receive a ring.

Each test station can be asked to open the line switch. When one between the main office and the trouble is opened it will cause the circuit to be balanced, and as a consequence quiet to the main office.

After locating the trouble between two test stations, a listening test can be made by having the intermediate stations put a momentary "short" across the circuit, the results being practically the same as in locating ground troubles.

Where the line is stripped of equipment, an approximate location of the "open" can be made by switching a grounded test set from one line wire to the other, and closely observing the volume of sound produced by the static discharge from the faulty line wire against that of the good wire. That is, their static capacity will be about in proportion to their lengths. This test is similar in effect to the test made on Morse circuits, with which all wire chiefs are familiar.

SPECIAL METHODS OF LOCATING CROSSES.

In locating crosses on a dispatcher's circuit, more care must be taken, as a low resistance cross may blow fuses, fuse relay points or do other damage where attempts are made to signal without first having secured some idea of the probable location and nature of the trouble. It is much safer to make a preliminary talking and listening test with one or two stations.

High resistance crosses will cut down transmission, and may partially interrupt the signals, although some such crosses are so high in resistance as to be only noticeable in the transmission.

A selective signaling circuit with a large number of stations may be noisy to one terminal and quiet to the other, or may be noisy to the middle stations and quiet to both terminals. This effect is chargeable, in part, to the numerous signal bridges across the line.

It is advisable to frequently inquire of some scattered stations to ascertain if any section has developed an unbalanced condition, causing any noise which is not discernible to the main office.

Considerable trouble is experienced from loose connections and high resistance joints in the main circuit. Much trouble has come also from the use of old telegraph wires in which were poor sleeve and hand joints.

In some unimportant circuits wires of two gauges are used, and in others one wire of iron and one of copper. Where this is compensated by cutting in the transpositions little trouble is experienced, but where wires that are not similar are maintained throughout an unbalanced and noisy circuit is the result.

In testing for slight noises on any circuit it must be kept in mind that the noise may become almost imperceptible by cutting off a greater part of the

* From *Telephony*.

Digitized by Google

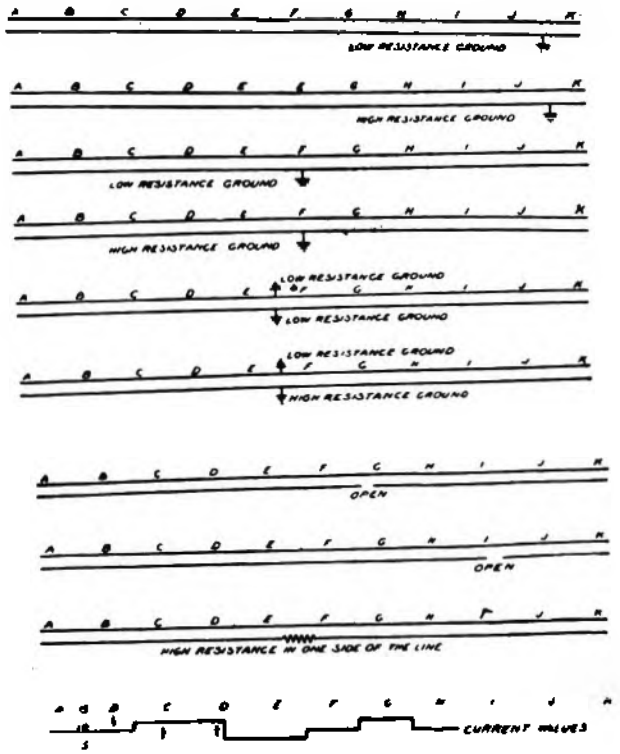
capacity. That is, a high resistance joint, loose connection or high resistance ground may produce a light noise, which will almost altogether disappear when the greater part of the line is taken off by "shorting" or opening the line.

As an instance, a line is reported noisy to the exchange operator, and on cutting off the line a listening test on both the line and drop will show clear. But when the drop is cut through to any long line a noisy circuit is the result.

The trouble is on the drop side, but as there is not sufficient static capacity in this circuit, no noise is perceptible until a line is attached.

In testing for any difficult line trouble it is very good practice, if convenient, to have some one at the distant terminal "listen in" and check the tests.

A lineman looking for a cross between two stations, being unable to get any help from the master station, resorted to a scheme of having the first station each way from the trouble "listen in" while he grounded one side of the circuit at some point between the stations.



FIGS. 1-10.—DIAGRAMS OF VARIOUS KINDS OF CIRCUIT TROUBLES, ETC.

On the first test the circuit was noisy to "A" and likewise on the second test, but decreased in volume, while on the third the circuit was quiet to "A" and slightly noisy to "B," indicating that the trouble was between the second and third testing points.

The following diagrams are to represent a metallic dispatching telephone circuit 100 miles in length and, as indicated, in an unbalanced condition.

For reference the stations are lettered and the line considered as ten miles between stations.

Conditions with respect to transmission and signaling for each circuit are indicated under (1) and (2) corresponding to the following conditions of the line:

(1) Line normal with all signal bridges regular.

(2) All equipment removed.

Fig. 1. (1) Very slight if any noise to A. Very noisy to K.

(2) Considerable noise to A. A roar at points near the trouble and especially at K.

No interruptions to signals.

Fig. 2. (1) Slight noise to stations near the trouble.

(2) Slightly noisy to all stations and likely serious to J and K.

No interruptions to signals.

Fig. 3. (1) Noisy to all stations and especially those nearest at each side of the trouble.

(2) A roar to all stations.

No interruptions to signals.

Fig. 4. (1) Slight noise at A and K, increasing toward trouble.

(2) Unless the ground is very high the circuit will be very noisy, increasing toward the trouble.

No interruptions to signals.

Fig. 5. (1) Quiet to all stations.

(2) Very slight, if any, noise.

Interruption to both signals and transmission (equivalent to a short-circuit).

Fig. 6. (1) Noisy to all stations, increasing toward the trouble.

(2) Very noisy to all stations.

Unless the ground is very high in resistance the transmission will be materially reduced and the signals to stations near and beyond the trouble interrupted.

Fig. 7. (1) Slight noise at A, increasing toward I. Very noisy near the trouble and at J and K.

(2) Very noisy to all stations.

Signals and transmission interrupted at the break.

Fig. 8. (1) and (2) Very noisy to all stations.

Signal interrupted at F, and if selectors have not a very wide range of current possibly all fail. Transmission practically total interruption.

Fig. 9. (1) Noise proportional to the amount of added resistance in the fault. 100 ohms-circuit quite noisy to the adjacent stations, but not excessive to A and K. 1,000 ohms-circuit very noisy to all points.

(2) 100 ohms or more likely total interruption.

With 100 ohms in the fault there would likely be no interruption to signals, but with 1,000 ohms there would likely be such a voltage drop between E and F as to so change the current values to stations beyond E that the signals would fail.

Selective signal system failures due to line troubles having been explained in the preceding diagrams, we will now consider equipment troubles.

A large percentage of the failures, which are not due to change of line conditions, are chargeable to battery troubles and not to the equipment.

A selective signaling system with a current range of from 5 to 15 milliamperes may be installed with sufficient battery to produce 10 milliamperes in all bridges, and with an individual adjustment ranging from the maximum to the minimum. That is, some

Digitized by Google

selectors are adjusted up to 10 milliamperes, others down to 10 milliamperes, with a result that any added current freezes up those adjusted up to 10 milliamperes, while a reduction in current fails to pull up those adjusted down to 10 milliamperes.

Investigation of selector failures will develop the fact that not more than one case out of a hundred is due to actual defects in the mechanical parts or electrical features, except when chargeable to improper adjustment, changing current conditions, or both.

Current changing conditions are sometimes due to wire or equipment troubles, but more often to the battery itself.

A total failure on a clear line means main office trouble, and can be located by observing a series of signaling operations which will indicate whether the failure is due to the local circuit of the master selector or is in the main battery circuit, where local tests will easily develop its source.

The failure of one way station selector may mean faults developing in the individual selector or its combination at the main office, but in most cases it will be found to be a changed current condition on the line or in the local of the selector.

Share of Work Done by Terminal Batteries.

BY M. S. CLINE, LYNCHBURG, VA.

Referring to question No. 40 under the heading "Questions and Answers" in TELEGRAPH AND TELEPHONE AGE for May 1, it is not clear to me that the answer given is entirely correct; that is, where the resistance and voltage are fixed. I assume that the batteries referred to are terminal batteries in which case it is obvious that instead of the deterioration of the battery at one terminal shortening the life of the battery at the other terminal or even exhausting it at all, it will have the opposite effect.

For example, let A and B represent the two terminals each with a battery of 100 volts working to a line of 2,000 ohms resistance, including the internal resistance of the battery which is immaterial for the purpose of illustration and therefore may be disregarded. This gives a total voltage of 200, and $\frac{200}{2,000} = \frac{1}{10}$ ampere, or 20 watts, ten watts from each battery. Then assuming that the battery at B has dropped to 50 volts the total voltage is then 150 and $\frac{150}{2,000} =$ .075 ampere, or 11.25 watts, showing 7.5 watts for the battery at A, thereby reducing its work one-fourth.

Were the battery at A increased to 150 volts to compensate for the loss of 50 volts at B, it is true that more cells would be required at A, yet no more work would be required of it than in the first instance, which is 10 watts. This is clearly sustained by Ohm's law governing current and work.

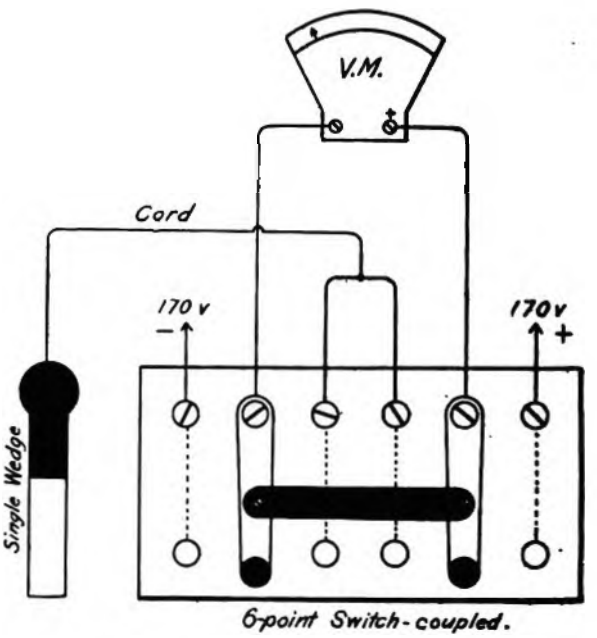
In a fifty-volt loss at B the current supplied to the line is reduced 25% and so remains until the battery at B can be built up or that at A is increased. In practice this condition generally obtains; that is, the defective battery really prolongs the life of the good battery where the latter is unvarying during such period of weakness and does not exhaust the good battery as the question and answer indicate.

Insulation Testing Apparatus.

BY R. W. A. HORNER, LYNCHBURG, VA.

The accompanying diagram shows the connections of a combination of simple apparatus for quick testing of line insulation. It consists of a voltmeter, a six-point switch and a single-conductor switch cord.

All that is needed to do is to insert the wedge in the spring jacks of the main switchboard with the brass side to the line underneath any wedges that may already be in the jacks. This connects the line directly to one polarity of the testing battery through the voltmeter, and with a throw



ARRANGEMENT OF SWITCHES FOR INSULATION TEST.

of the switch to the opposite side gives the reading of the other polarity, all of which is done without removing any plugs or wedges from the switchboard, thus keeping the existing connections intact.

This device is due to Mr. M. S. Cline, repeater chief in this office, and was suggested to him by the principle involved in the new Western Union volt-mil-ammeter testing apparatus, and it has proved a good method for quickly testing a number of wires. Its simplicity and the ease with which it can be mounted on the switchboard is obvious and it is offered to those who might care to use it until the standard testing apparatus can be installed.

The Military Telegrapher in the Civil War.

PART LVIII.

An interesting story of the siege of Vicksburg and of the operations around Fort Donaldson, from a telegraphic standpoint, is told by Mr. James Q. Mason in recounting his military telegraph experiences during the civil war. Military telegraphers had peculiarly trying duties in the service, and were as much exposed to danger as the soldiers fighting on the line, because their work was largely of a pioneer character. The building and operation of telegraph lines in a country overrun with enemies required men of extraordinary courage and strength of character, and the records show, without any question in a single instance, that the military telegraph corps was composed wholly of such men.

Mr. Mason's contribution toward the record of the achievements of these brave men is reproduced in part as follows:

"I enlisted," he says, "in the Chicago Mercantile Battery August 7, 1862, as a high private, a privilege which was freely accorded to all able-bodied persons in those perilous times. I was ordered to Memphis, Tenn., November 1, after three months' camp life in Chicago. On arriving at Memphis I participated in the Tellahatchee march. General Grant was supposed to be marching from Holly Springs for Vicksburg and we were to form a junction with him somewhere in Mississippi. We, however, with General Morgan L. Smith were ordered back to Memphis, at which place we arrived after an absence of three weeks. We then proceeded down the river to Vicksburg and up the Yazoo River. After landing, a few hours' march brought us into position in the rear of Vicksburg. The commanding and musketry fire were very deafening and sharp. The shells went screeching over our heads in a manner that suggested grave thoughts and filled a fellow full to the brim with homesickness. I don't believe there was a man in our company that felt real well. Our battery was stationed on the extreme right, where it was said the enemy would undertake to break through and escape when driven from the fort (this was Sherman's attack on Vicksburg), but they were not driven from their position. After two or three days' hard fighting by our centre and left our army quietly withdrew in the stilly night, being firmly convinced, no doubt, of the truth of the old adage that 'He who fights and runs away, will live to fight another day.'

"From Vicksburg my company was ordered up White River to participate in the attack on Arkansas Post. In this our army was entirely successful, capturing about 13,000 prisoners. I had been very much under the weather for some time previous to this battle, and within a day or so after the fight I was compelled to take to bed with typhoid fever.

"This was the hardest service I experienced in my connection with the army. Five long weary months in the hospital, two at Jackson Hospital, Memphis, Tenn., and three in Fifth Street Hospital, St. Louis. I believe it was in June, 1863, that I was detailed from Fifth Street Hospital and ordered to report to Captain Samuel Bruch at Louisville, Ky., for duty. My memory of Captain Bruch is always fresh and green. He was a splendid man and a good and kind officer. I reported as ordered and Captain Bruch sent me to Captain J. C. Van Duzer at Nashville, Tenn. There is no need of eulogizing Captain Van Duzer. Every one who knew him liked him for his unquestioned ability and hearty, pleasant manner.

"Arriving at Nashville, Captain Van Duzer ordered me to Fort Donaldson. After eight months' service here at detailed wages of $13.00 per month, I was furloughed indefinitely by the War Department and thereafter Captain Van Duzer paid me operators' wages, ordering me to Nashville. After a month or two on the Huntsville, Ala., wire I was detailed to the Louisville circuit, which was an extremely lively string, with Zeph Morris at the Louisville end. After several months' pleasant, though hard, labor on that wire I was ordered to Cairo, Ill., as assistant manager of the joint military and civil offices. At this point I remained until the close of the war, the last four or five months of which I was manager and government cipher clerk, being routed out at night frequently by generals passing through who desired their messages ciphered. During all this time and until some time after the war closed Cairo was the jumping-off place, telegraphically speaking, and the business there, both military and civil, was very heavy. There were only four wires and the telegraph receipts were $3,000 or $4,000 per month. Military business for points south was all enveloped and sealed by the Cairo manager and sent down the river by steamboat captains, or, rather, in the captains' charge. All steamboat captains were obliged to report to the Cairo manager and receive a military telegraph clearance before they could proceed in any direction from Cairo. I was mustered out of the service August 8, 1865."

After the war Mr. Mason returned to active telegraph service, entering the employ of the Illinois and Mississippi Telegraph Company at Chicago. He afterwards became connected with the Western Union Telegraph Company and later with the Wabash Railroad as division operator, chief dispatcher and train master. Subsequently he entered the service of the Northern Pacific Railroad Company at Tacoma, Wash., as assistant superintendent of telegraph. Mr. Mason is now in the Western Union service in the Northwest.

When Mr. Carnegie Was a Telegraph Operator.—Leslie's Weekly of May 25 publishes an article by Mr. D. H. Bates of New York entitled "When Mr. Carnegie Was a Telegraph Operator." The story is given in connection with the description of the unveiling of the bronze tablet in Pittsburg in memory of the volunteers from Alleghany County, Pa., who served in the United States Military Telegraph Corps during the Civil War.

Railway Test Boards.

Many railroads have installed and are adding from time to time telephone circuits along their rights-of-way, these being generally for message work, in addition to the train wires already in service. When a plurality of circuits of this type extend along a railroad, some means of testing the lines and locating trouble upon them is essential.

The test board shown in Fig. 2 consists of a number of jacks arranged in two parallel rows, with a grounding jack at the bottom. The lines are brought into these jacks and are carried through the board and out to the line again from the jacks on the other side. The wiring diagram, Fig. 1, illustrates how this is done. On telephone train dispatching circuits, jacks 1 and 3 and 2 and 4 are generally used for the train wire, while jacks 9 and 11 and 10 and 12 are employed for the message circuit. The selector and telephone sets are bridged across the train wire in one case through a key, and across the message wire in the other case through a key on the other side of the board. This apparatus is tapped off the inside contacts of the jacks so that when a plug is inserted in the jack,

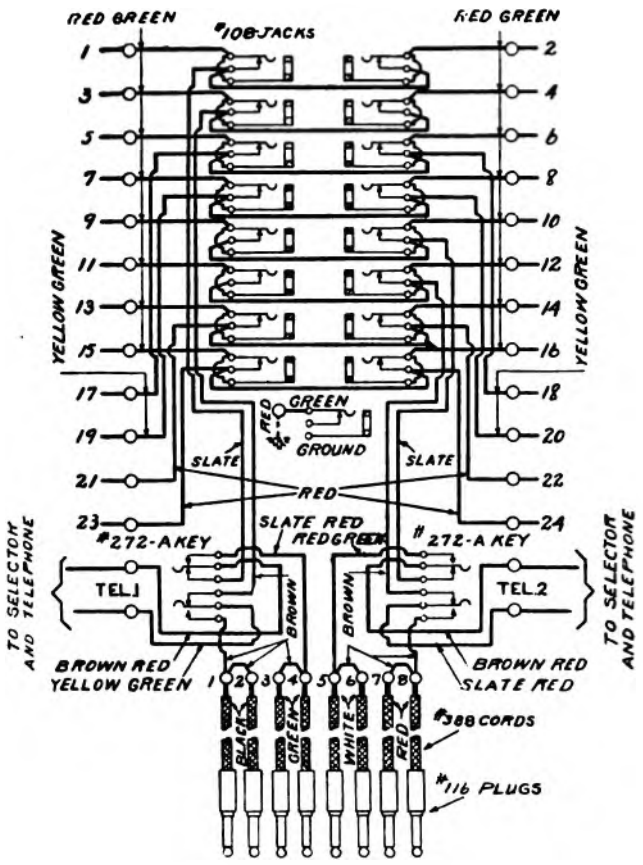

FIG. 1.—WIRING DIAGRAM OF TEST BOARD.

the selector and telephone apparatus is cut off and thrown across the cord circuits by means of the keys.

Inserting one cord of a given color in a jack and the other cord of the same color in the ground jack, grounds that wire. A pair of wires may be short-circuited by inserting cords of the same color in the two jacks to which those wires are connected. A wire may be opened by inserting a plug

FIG. 2.—GENERAL VIEW OF TEST BOARD.

in the jack, care being taken to see that the plug of corresponding color is not used elsewhere.

By means of this apparatus which is manufactured by the Western Electric Company, the greatest flexibility is given to the telephone lines in railway service, and it becomes possible to make all the simple tests ordinarily required on lines of this character.

"Gill Selectors for Telegraph Service" is the subject of a neatly gotten up pamphlet issued by the United States Electric Company, 284 Pearl Street, New York. The many uses to which these selectors may be put in telegraph service are set forth, and some excellent views of the apparatus are shown. The development of this selector is gone into historically, and its application and operation are stated very clearly, the diagrams of typical circuits being of a high order of the engraver's art. The selector is a very important part of the telegraph and telephone equipment of the up-to-date railroad.

In these days of rapid progress and development every operator should familiarize himself with the technical side of his work. Mr. Jones' book, "Pocket Edition of Diagrams and complete information for Telegraph Engineers," should be studied by all telegraphers. It is clearly written, in plain understandable English, and fully illustrated. When this book is mastered it fits the student for better positions in the service. The price is $1.50. Address Telegraph and Telephone Age, 253 Broadway, New York.

The Telegraph Intensifier Company has been organized at Denver, Col., with a capital stock of $50,000. The incorporators are: W. A. Deuel, C. C. Anthony, and C. A. Parker.

How Faults on Telegraph Lines are Located.

(Concluded from page 355, May 16 issue.)

TO LOCATE A GROUND.

Select a good wire, which should, if possible, be on the same pole line as the defective wire; have this good wire looped back to the defective wire at the first convenient station beyond the fault. Connect the testing set to these wires at the home station by inserting the wedges *L*-1 and *L*-2 in the line spring jacks at the switchboard. With the exception of the special case to be mentioned later, *L*-1 should connect with the good wire and *L*-2 with the defective wire.

At the testing set, insert the connecting plug in the jack marked "Loop," which makes the connections as per Fig. 8. Adjust the rheostat *R* reading of the rheostat *R* as the "Varley" resistance. This figure represents the difference between the resistance of the defective wire from *L*-2 to *P*, and the resistance from *L*-1 to *P* around through the distant station, the latter comprising the total resistance of the good wire from *L*-1 to the distant station plus the resistance of the defective wire from the distant station to *P*. We therefore proceed to subtract the "Varley" from the "Loop" resistance and divide the remainder by 2; this gives us the resistance of the defective wire from *L*-2 at the testing station to *P*, the point at which the fault is located.

Having obtained this value, it is only necessary to convert the "ohms" (which in the case of a wire, may be considered an electrical measure

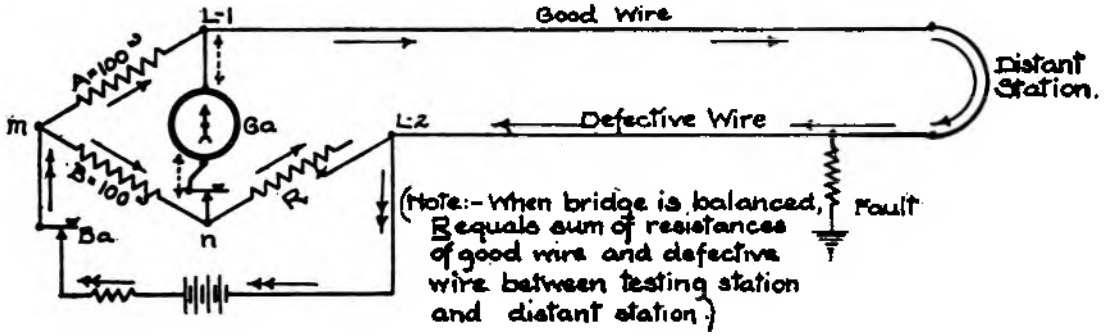

FIG. 8.—DIAGRAM OF CONNECTIONS FOR LOCATING GROUNDS.

until the galvanometer indicates a balance and record the reading of the rheostat as the "Loop" resistance. The presence of the ground has no effect in this case as the rest of the circuit is insulated and therefore none of the testing current flows through the ground.

Now transfer the plug to either of the jacks

of distance) into "miles" or "feet" in order that the lineman may know where to look for the trouble. This may be done in several ways. If the defective wire is of the same gauge throughout its length and has but a few hundred feet of cable in its make-up, we can simply divide the resistance in ohms from the testing station to

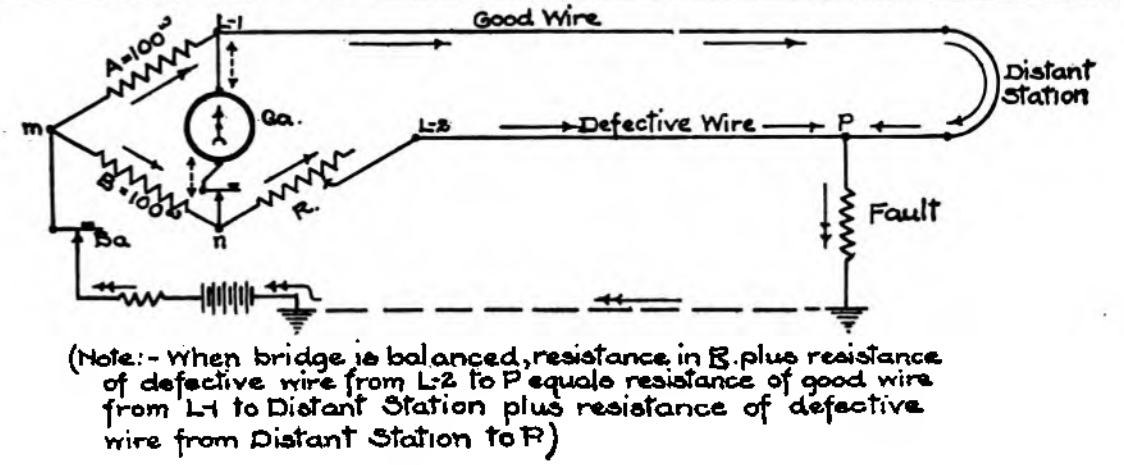

FIG. 9.—DIAGRAM OF CONNECTIONS FOR LOCATING GROUNDS.

marked "VG+" and "VG—"; if the fault has a positive ground potential the "VG—" jack should be used and vice versa. The connections will then be as per Fig. 9.

We now proceed to balance the bridge, and when this has been accomplished, record the

the fault by the number of ohms resistance per mile of the wire, and obtain a fairly accurate result, particularly if the trouble is but a few miles from the office. A safer plan, however, is to measure the resistance of the defective wire from the testing station to the farthest testing point

Digitized by Google

to which it is O. K., and base our distance calculations on the resistance from that point to the fault.

The wire chief should frequently measure the individual resistances of the wires under his care, keeping a card or book record of these resistances between the various stations and under varying temperature conditions, etc. Such measurements can be taken at times when idle wires are available and are not only valuable for use in locating grounds or crosses, but often lead to the detection of poor joints, etc.

In general, it should be remembered that when trouble is found at a point other than the one shown by the location tests, either our calculations or the data on which they are based are almost certain to have been the cause of the error. In such cases the figures should be carefully checked, and every effort made to discover the incorrect values used, in order to avoid future difficulties of the same kind.

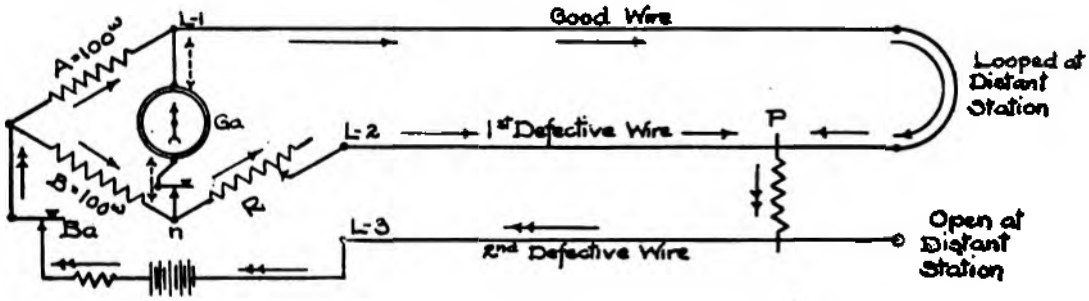

FIG. 10.—DIAGRAM OF CONNECTIONS FOR LOCATING CROSSES.

TO LOCATE A CROSS.

FIRST METHOD. — Where only one of the crossed wires is accessible to the testing station, the other wire or wires with which the accessible wire is in contact are grounded at any convenient point, thus converting the fault on the accessible wire into a ground. The trouble is then located as per the preceding instructions "To locate a ground."

SECOND METHOD.—Greater accuracy in locating crosses, particularly in wet weather, will be obtained by the following plan, known as the "Metallic Varley" test. This method should therefore be used in preference to the first method described, whenever two of the wires crossed together are accessible to the testing station. One of the crossed wires is looped back to a good wire, preferably on the same pole line, at the first convenient point beyond the trouble, and the loop thus formed is connected to the testing set at the testing station by means of the wedges *L*-1 and *L*-2. The other crossed wire is left open at the distant end, and at the testing station is connected to the testing set by the wedge *L*-3. If other wires are also crossed with the two mentioned, they are left open at both ends. At the testing set, the connecting plug is inserted in the "Loop" jack of the jack box, which leaves the wire connected to *L*-3 open and connects *L*-1, *L*-2 and the bridge in a manner similar to the arrangement shown in Fig. 8. The "Loop" resistance is then measured and recorded as per preceding instructions, after which the connecting plug is transferred to the "MV" jack. This makes the conditions as shown in Fig. 10. A comparison of the two figures will show that the connections of Fig. 10 differ from those of Fig. 9 only in providing a metallic return circuit from the fault at the point *P* to the battery *Ba*, instead of forcing the current to return from the fault at *P* through the earth to the battery *Ba*. This plan has the decided advantage of almost eliminating errors due to leakage.

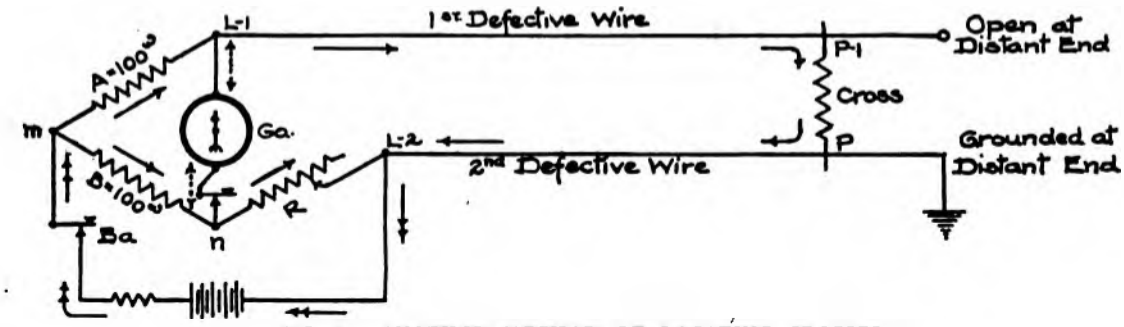

FIG. 11.—ANOTHER METHOD OF LOCATING CROSSES.

THIRD METHOD.—In some cases of crossed wires, it is impossible to apply either the first or second methods mentioned as there may be no available good wires between the testing station and the distant office. A good location can then be made by the following method, provided the

Digitized by Google

resistance of the fault, that is, the resistance at the point or points of contact between the crossed wires, remains constant.

At the testing station, the two crossed wires are connected to the testing set by means of the wedges *L*-1 and *L*-2. The wire connected to *L*-1, which should be the one having the higher resistance if there is any difference between the two, is opened at the distant end; the wire connected to *L*-2 is grounded at the distant end. At the testing set, the connecting plug is inserted in the "Loop" jack, making the connections as per Fig. 11. The ground at the distant end being the

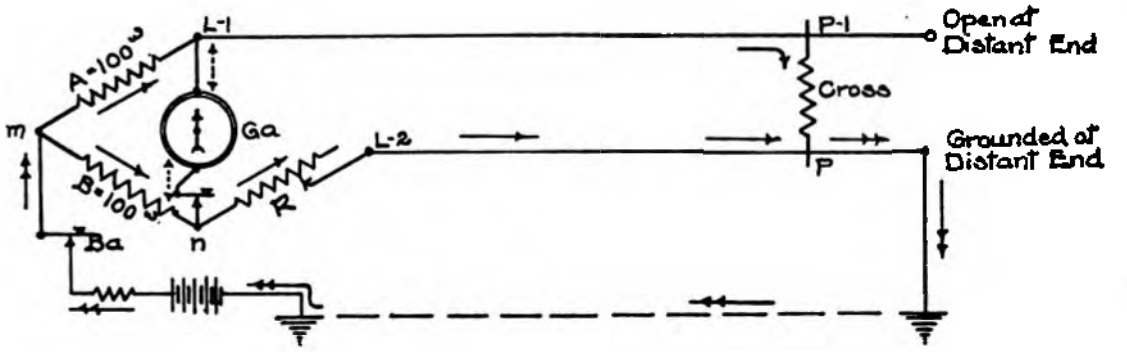

FIG. 12.—ANOTHER METHOD OF LOCATING CROSSES.

only one on the circuit, it has no effect on this measurement. A balance is obtained when the rheostat *R* is equal to the resistance between *L*-1 and *L*-2, which includes the wire between *L*-1 and the point *P*-1, the wire between *L*-2 and the point *P*, and the resistance of the cross itself at the points *P*-*P*-1. If a good balance is obtained without difficulty, that is, if the galvanometer needle shows no change for a few seconds after it has been brought to zero, it is fair to assume that the resistance of the fault is constant, and the reading of the rheostat *R* may be recorded as the "Loop" measurement. The connecting plug is then transferred to the "VG+" or "VG—" jack, using the "VG+" jack if the distant ground has negative potential and vice versa. The connections are now as per Fig. 12. It will be seen that for a balance under these conditions the resistance of the rheostat *R* must be such that when added to the resistance of the wire between *L*-2 and the point *P*, the sum will equal the resistance between *L*-1 and *P*, which includes the resistance of the wire from *L*-2 to the point *P*-1 and the resistance of the cross itself at *P*-*P*-1. In other words, the rheostat *R* represents the difference between the resistance from *L*-1 to the point *P* via *P*-1 and the resistance from *L*-2 to the point *P*. This reading of the rheostat may be recorded as the "Varley" measurement. It should be noted that the resistance of the wire beyond the cross, that is, between the point *P* and the distant end, does not enter into the measurement at all; this piece of wire, together with the ground connections, form the return circuit to the battery.

Calling the resistance from *L*-1 to *P* via *P*-1 the larger quantity, and the resistance from *L*-2 to *P* the smaller quantity, we have found that the sum of these quantities is the figure obtained in the "Loop" measurement, and the difference between these quantities is the "Varley" measurement.

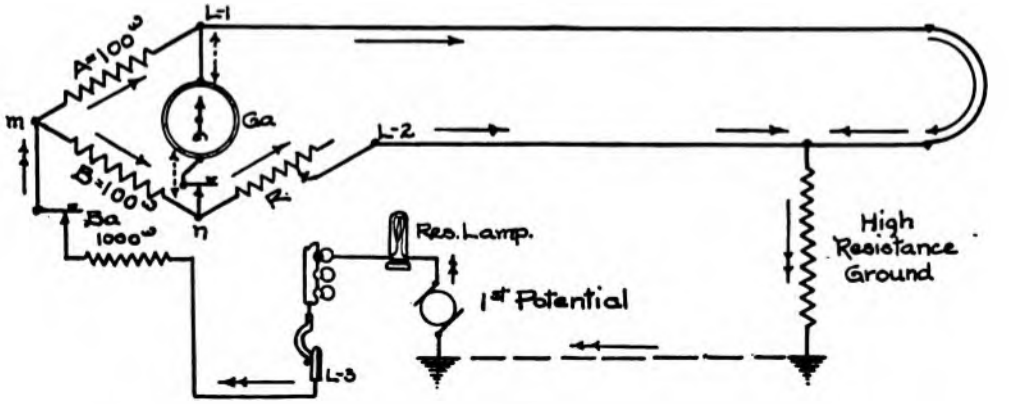

FIG. 13.—FIRST POTENTIAL SWITCHBOARD BATTERY TO BRIDGE.

HIGH RESISTANCE FAULTS.—Occasionally it will be found impossible to locate a fault by the foregoing methods, on account of the fault having an abnormally high resistance. Under such conditions the ordinary battery power used with the bridge causes such small deflections of the galvanometer needle that an apparent balance

Digitized by Google

may be obtained with the rheostat set at any point within wide limits; that is, the needle does not respond to variations of an ohm or two in the rheostat, as it should for an accurate balance. It is then necessary to use a higher voltage testing battery, which may be done as follows: The connecting plug at the jack box is inserted in the jack marked "HV" instead of in jacks "VG+" "VG—" or "MV." This disconnects the regular bridge testing battery, but instead connects the point *m* of the bridge, through the battery key *Ba* and a resistance of 1,000 ohms, to the *L*-3 wedge at the switchboard. This is shown in Fig. 13 where, for the purpose of locating a high resistance ground, the *L*-3 wedge at the switchboard is connected to a switchboard battery tap of the first potential. The conditions for balance in this case are of course identical with those shown in Fig. 9 and the explanation accompanying it. Fig. 13 shows a first potential switchboard battery applied to the bridge; it is allowable, in extreme cases, to use a second potential tap for this purpose, but no higher voltage than that should ever be used. For locating a high resistance cross by the second or "Metallic Varley" method a higher voltage than that of the regular bridge battery may be applied.

Unsteady Galvanometer Needle.—As stated in the sections on locating grounds and crosses, the good wire used to complete the loop in all location tests, should be on the same pole line as the defective wire under tests, if possible. If, for any reason, this plan is not followed, it will be found difficult to secure a good balance, owing to the currents set up in the loop by induction from neighboring circuits and other sources; when the two wires forming the loop are on the same pole line, these disturbances are almost entirely neutralized by the compensating effect of one wire on the other. When a loop has to be formed of wires located on different pole lines, therefore, the needle of the galvanometer will be unsteady, that is, it will "drift" from side to side, or swing over to one side for a few seconds, etc. Securing a balance under these conditions requires some skill, but can be rendered much easier by shunting the galvanometer.

Swings.—When a fault is intermittent, it is often advantageous to loop a Morse relay in the battery branch of the bridge, with the relay points arranged to close the circuit of a sounder or vibrating bell so located as to be readily heard by the one handling the testing set. The *Ba* key is then held down steadily, but the *Ga* key is tapped only while the sounder or bell is operated by the closing of the relay, which indicates that the swinging fault is in contact with the wire under test. The relay used for this service will be wired to a wedge at the switchboard, which can be inserted in the spring-jack in series with the *L*-3 wedge when the connecting plug at the jack box is in the "MV" or "HV" jacks.

Broken Wires.—The loop tests described herein cannot be directly applied to a broken wire, i. e., a broken wire cannot be looped back to a good wire at the distant end, and a reliable location of the fault obtained. In most cases, however, the broken wire becomes crossed with another wire which is intact, and a location of the trouble can be made on the latter. When two wires break and their ends become crossed together without touching any other wires, it is often possible to apply the third method of locating a cross because one or both of the broken wires usually make a contact with the ground which will serve in place of the ground applied at the distant station.

New Method of Overcoming Inductive Disturbances.

Mr. Frank Fisher, of New York, was granted a patent on May 23 (No. 993046) for a "System of transmitting signals electrically through conductors." The device includes a means for relieving the receiving coil from inductive disturbances of any and every origin, the line coil being placed in an insensible zone.

One of the objects of the invention is to provide a system of transmission, using local earth, wherein the receiving instrument will not be affected by disturbances due to variations in the earth's potential, or from parallel lines carrying heavy voltage. It is especially applicable in multiplex telegraphy, whether aerial lines or submarine cables, and obviates the use of the return metallic circuit generally used in connection with the telephone, irrespective of the delicacy of the magnetic field.

An important feature is its application in connection with the Wheatstone bridge, wherein the resistance on opposite sides of the receiver may be permanently balanced, so as to avoid the necessity for frequent balancing the resistance affected by the difference of potential due to atmospheric or terrestrial alternations, or disturbances arising from the motion and action of electric trolley cars.

Another important feature is its merit as an effective lightning arrester.

Mr. Fisher is a consulting electrical engineer in New York, and was born in Birmingham, England, February 12, 1847. He began his telegraphic career in his native city in 1862 and has held positions of importance in the cable service in various parts of the world. He was at one time superintendent of the French Cable Company and vice-consul of France at Sydney, C. B. He represented that company in establishing its New York office on an independent basis and afterwards joined the cable-repairing steamer *Pouyer Quertier* as electrical engineer. He was one of the electrical engineers in charge of the shore ends during the laying of the French West Indian cables.

Any book on electrical subjects can be obtained through Telegraph and Telephone Age, 253 Broadway, New York.

A Telegraph Superintendent's Problems

in these days of Telephone Train Dispatching, are telephonic as well as telegraphic.

Our organization, aside from its commercial basis, exists to serve you in both these fields. It brought out the Gill Selector, the pioneer and best-known device for selective calling, and the only selector successful from an operative and maintenance standpoint.

The members of our engineering staff are acknowledged leaders. Our energies are devoted entirely to electrical apparatus for railway service.

We know that telephone apparatus made for ordinary commercial use **will not be found satisfactory** in railway service. We are creating constantly new apparatus of special design and rugged character to meet the severest service requirements.

Call in on us at Parlor G at the Boston convention. Our exhibit there will include our new Selective Train order Semaphore system, based on the absolute control of signals by the dispatcher.

Oregon & Washington R. R. & Navigation Co.—Superintendent of Telegraphs has authority to construct 118 miles of telephone train dispatching circuit between Portland and The Dalles. Also 185 miles of telephone line from Portland to Seattle for ordinary railroad work as well as train dispatching.

Central Railroad of New Jersey is now installing a telephone system on 40 miles of New York & Long Branch Railroad.

Chesapeake & Ohio Ry. Co. will have completed by June 20, 274 miles additional between Old Point Comfort and Clifton Forge, Va., via Gordonsville and Charlottesville. For the budget next year there has been included in its estimate, an additional telephone train dispatching circuit of 124 miles between Ashland, Ky., and Lexington, Ky.

Oregon Short Line will be double-tracked probably within the next four or five years. This, with the block signals may render telephone installation for train dispatching purposes unnecessary. In any event there will be very little telephone installation until this work is done.

Pittsburg and Lake Erie R. R. will probably install telephone train dispatching service next year.

Seaboard Air Line Railway is now stringing 668 miles of additional telephone train dispatching circuit.

San Pedro, Los Angeles & Salt Lake R. R. Co. contemplates installing telephone train dispatching system in the near future.

Richmond, Fredericksburg & Potomac R. R. has a simplex blocking circuit covering the entire line.

Pere Marquette R. R. Co. has in contemplation and in course of construction 425 miles of telephone train dispatching circuit in addition to that already installed. The entire system will be equipped in the near future.

Chicago, Great Western is now installing telephone train dispatching system on 75 miles of double track and 172 miles of single track.

Chicago, Milwaukee & Puget Sound Ry. is now constructing 728 miles of telephone train dispatching circuit.

Chicago, Terre Haute & Southeastern Ry. is installing a circuit of 155 miles which went into operation June 1.

Denver, Northwestern & Pacific Ry. Co. is using the telephone conjointly with the telegraph for train dispatching.

Great Northern Ry. is now installing telephone train dispatching on 253 miles of single and 33 miles of double track.

Missouri, Kansas & Texas Ry. has ordered the materials for installing 700 miles of telephone train dispatching circuit this year.

Norfolk & Western R. R. has 100 miles of telephone train dispatching circuit now in course of construction.

El Paso & Southwestern System is using the composite telephone, known as the telegraphone, with excellent results. The use of this apparatus is responsible for the company's not having installed the train dispatching telephone, which no doubt will eventually be done as the advantage of the telephone is very apparent, and the operating department officials are very favorable to its adoption.

* Single and Double Track.

† 1910 figures.

‡ Oregon-Washington Railroad and Navigation Company, 1808 miles; Southern Pacific Lines in Oregon, 652 miles.

The Railroad.

Telephone Dispatching on Pennsylvania Branch Line.—The Pennsylvania Railroad Company will equip its Bellwood division with a telephone train dispatching system.

Continental Telegraph Company Purchased.—The Chicago, Milwaukee and Puget Sound Railway Company has acquired the rights and property of the Continental Telegraph Company in North and South Dakota, Montana, Idaho and Washington.

Hours-of-Service Law Upheld.—The United States Supreme Court on May 29 rendered a decision upholding the constitutionality of the "Hours-of-service law for railroad employes" in the test suit instituted by the Baltimore and Ohio Railroad Company.

Supreme Court Decision Against Tobacco Trust.—The United States Supreme Court on May 29 rendered its decision in the case of the Tobacco "trust" ordering the dissolution of the trust which is held to be a combination in restraint of inter-state trade. The trust was given the opportunity to reorganize under the immediate supervision of the Circuit Court of the second New York district.

Western Union in Kansas.—The litigation over the right of the Western Union Telegraph Company to do business in Kansas has been settled on the basis of a recently enacted law in that state. The new law requires foreign corporations to pay a charter fee on the actual amount of capital used in the state. Six years ago an effort was made to prevent the company from doing business in Kansas because it had not a charter, the company having refused to pay a charter fee on its entire capital stock. The Supreme Court reversed this law.

Current Practice in Rules for Telephone Train Dispatching.

BY JOHN W. BARNEY OF NEW YORK.

A number of the railways of this country and Canada which have adopted telephone train dispatching have also issued rules and instructions governing the use of the new equipment. These vary from a few general statements in a half-dozen paragraphs, mimeographed, to be sent to employes, on one road, to the handsome, linen-bound pocket book of instructions issued by the Louisville & Nashville Railroad Company. On the Baltimore & Ohio Railroad these rules are incorporated into a 49-page book, covering block signal and interlocking as well as telephone rules. The Canadian Pacific Railway, the Delaware, Lackawanna & Western, the New York, New Haven & Hartford, the Lehigh Valley and the Lake Shore & Michigan Southern rules are admirably concise. Some of the roads, including the Great Northern, the Southern Railway, the Union Pacific Railroad and the Queen & Crescent incorporate in their telephone train dispatching instructions directions for patching circuits, while on other roads like the Erie, the Atlantic Coast Line and others, instructions in regard to patching are given orally by the inspector on duty, who is governed entirely by the circumstances in the individual cases. On the other hand there are a few roads which report no specific rules for telephone train dispatching, as it is found that the telegraph train dispatching rules will serve, the telephone being understood to be meant in cases where the telegraph is referred to.

In such survey and study of these rules as the writer has had occasion to make, three points stand out as insisted upon with practical unanimity as essential in rules governing this service. They are: the restriction of the train-order circuit, with more or less rigidity, to messages concerning train movements only; the elimination, and in some instances the prohibition of the use of the word "Hello" in answering telephone calls, and the necessity of repeating or spelling out certain parts of train-order messages to insure accuracy.

The train dispatcher, under the most of these rules is in absolute control of the train circuit and may assume control of the message circuit when circumstances require. The dispatcher's permission for the use of the train-order wire by officials other than his operators is required on the Atlantic Coast Line, the Louisville & Nashville, the Grand Trunk, the Central Vermont and the Evansville and Terre Haute. The Bessemer & Lake Erie excepts from the dispatcher's permission the superintendent, the assistant superintendent, trainmasters, train supervisors, the chief train dispatcher, the road foreman of engines and line foremen. The Georgia Railroad excepts the superintendent, trainmaster, traveling conductor and traveling engineer. The New Iberia & Northern allows employes to use the telephone circuit on permission from the agent or other person in charge of the telephone, and the Queen & Crescent rules state that the train dispatcher's circuit is to be used exclusively for handling train orders "excepting as may be directed by proper authority."

Following general directions requiring the dispatcher to write orders as he gives them and to underscore words as repeated back for verification, the requirements looking to the insuring of accuracy in recording these oral communications agree upon the principle of verifying by spelling out or by repetition words upon which there is a possibility of error in comprehending, while they differ considerably in the means by which the desired safeguards are to be obtained.

Some of these differences have evidently grown out of the isolated individual formulation of rules and are not significant as tending to establish principles. The requirements of repetition by spelling or otherwise cover, generally, order, train and engine numbers, and station names, and in some cases are extended to cover track numbers and names of conductors. The larger number of roads using telephone train dispatching require that names and figures shall first be pronounced and then spelled out, while about a quarter as many roads call for the spelling first and the pronouncing later. Two roads call for the pronouncing and repetition of names and numbers without requiring the spelling out, two others call for spelling without providing for the sequence of operations or the manner of spelling, and one line requires only the repetition of figures but does not provide for spelling out, nor indicate the manner in which they are to be repeated. One road appears to be supercautious in reversing its requirements for the two classes of figures. Thus time figures are required to be first spelled and the numerals then pronounced, while train and engine numbers must first be pronounced and the figures then duplicated.

In the treatment of the cipher, practice varies, a number of roads calling for the spelling out "n-a-u-g-h-t" or "n-o-u-g-h-t," while a smaller number use "o," in one instance the rule calling for the use of the syllable "Oh."

In multiples of ten some of the principal roads spell out as one word, thus: "f-o-r-t-y," while others require "f-o-u-r-O" or "f-o-u-r n-a-u-g-h-t." One road, however, directs that ten shall be spelled out as "o-n-e O."

In double numbers the rules show variations. The number 12 may be sent as "t-w-e-l-v-e" or as "o-n-e t-w-o" under differing rules and in such numbers both the examples following are authorized and required by different rules: "52. f-i-v-e t-w-o," "92, n-i-n-e-t-y t-w-o."

In larger numbers 100 may be spelled: "o-n-e n-a-u-g-h-t n-a-u-g-h-t" or "o-n-e d-o-u-b-l-e O." One thousand may be spelled, according to one set of rules: "o-n-e t-r-i-p-l-e O."

In mixed hundreds, in figures like 305, for example, "naught" or "O" are good practice, according to different rules. One road authorizes the spelling of mixed numbers of three places as: "o-n-e e-i-g-h-t-y s-e-v-e-n," while the larger number of roads require, in such cases, the spelling of each figure separately.

In numbers of four places opinion seems to be divided, according to the rules at hand. The fol-

Digitized by Google

lowing examples of authorized practice are taken from the several instructions, the hyphen denoting those words required to be spelled a letter at a time:

2550. t-w-o f-i-v-e f-i-v-e n-a-u-g-h-t.

Fi-f-t-y n-i-n-e n-i-n-e-t-y e-i-g-h-t, Five, nine, nine, eight.

O-n-e t-h-r-e-e o-n-e f-i-v-e. Thirteen fifteen.

2835. 2-8-3-5. Twenty-eight, thirty-five.

In time numerals the general practice seems to be to follow colloquial usage in spelling out hours and minutes, time being given in minutes past the hour, as: "1 o-n-e hour 45 f-o-r-t-y f-i-v-e minutes;" "6.15, s-i-x f-i-f-t-e-e-n."

Many of the rules insist upon the exercise of the utmost care to obviate liability of misunderstanding or error. Two companies, the Southern and the Northern Pacific, have endeavored to guard against phonetic pitfalls due to the similar sounds of P, B, T, D, etc. The Southern rules suggest that the alphabet be scaled in such cases, as: P., N, O, *P*; B., A, *B*; while the Northern Pacific rules direct the spelling out of the letter for identification, thus: T., tea; B., bee; C., see, etc.

Although a number of the rules require the use of a conversational tone of voice in transmitting orders and reports and impose care in the use of the telephone, and a prescribed position with respect to the mouthpiece of the transmitter, the important subject of the use of the instrument is treated in none of the rules more fully than in the booklet of the Louisville & Nashville Railroad Company. One of the commonest faults in the use of the telephone is the failure to speak properly into the transmitter. The need of instruction is so general as to warrant the mention here made, which is drawn mainly from the Louisville & Nashville rules.

It is not necessary to talk in a loud or sharp tone of voice into the telephone transmitter, as the only result will be to confuse the voice vibrations and render the utterance unintelligible to the receiver. For the best results the mouth of the speaker should be within about one-half inch of the mouthpiece of the transmitter and the speaking should be in a tone somewhat lower than in ordinary conversation. Words should be pronounced slowly and distinctly, a monotone being recommended, with no emphasis or inflection. It is desirable that all syllables should be pronounced without slurring, while the "r's" may be slightly rolled, as we hear from central station operators in the larger cities. While speaking the mouth must not be averted from the instrument, as the vibrations will then fail to enter the transmission orifice and be lost. The position of the transmitter mouthpiece should be inclined slightly upward from the horizontal. Under no circumstances should the diaphragm of the transmitter be hit or touched.

The receiver should set snugly against the ear, not only to prevent the entrance of external noises, but because the increase by even the fractional part of an inch of the distance of the diaphragm from the ear may be equivalent to the loss in transmission efficiency represented by a hundred or more miles of wire. If, when the foregoing requirements are observed, the message cannot be heard plainly, the fault is on the line or in the receiver, though seldom in the latter. If the receiver is at fault, the rubber cap should be removed and the magnet terminals examined and cleaned of dust or dirt. Care must be exercised in handling the diaphragm to avoid denting or bending it in the slightest degree. It should be handled as little as possible. In cases where it is surmised that the magnetic strength of the armature has failed it may be tested by taking the metal diaphragm and placing its edge across the magnet poles. If it is supported while the receiver is held in an upright position, the magnetic action is good; but if not, the receiver should be removed immediately and a good one substituted.

Receiver and transmitter cords should never be twisted or allowed to remain in that condition, if so caused by accident. The small wires inside the cord will become broken and make the telephone noisy and unsatisfactory. A defective cord may be detected by holding the receiver to the ear and shaking the cord. If it is broken or not making perfect contact, it causes a grating noise in the receiver. No weights or pulleys should be attached to the cords under any circumstances, and no moisture should be allowed on or near them.

Frequent inspection of binding posts is necessary. A loose connection, while it may not cut out the service altogether, will lower transmission and make the telephone unsatisfactory. The telephone must not be allowed to come in contact with telegraph keys or other telephone instruments. Metal articles should never be placed on or near the telephone instruments; such articles are likely to short circuit the apparatus and cause trouble.

The rules do not alter the force of the "O. K." or "Complete" of the telegraph service, but they agree substantially upon "Right" or "All right" as acknowledgment of an order, and on brevity of statement in answering calls, both on the part of the dispatchers and operators. They are at practical unity in forbidding any changes by operators in the wiring or equipment of the telephone train dispatching service and in requiring the prompt reporting of all trouble on the circuit to the dispatcher.

How to Remove Crystallized Copper and Blue Stone from Battery Jars.

Mr. G. B. Still, operator for the Southern Railway at Lima, Va., has found an easy way to remove crystallized copper and blue stone from the bottom of battery jars without breaking the jars. He recommends placing the jar in the sunshine upside down on a board for thirty-six to forty-eight hours. The crystals will separate and fall from the bottom of the jar. If the mass is tightly set, the whole will slowly slide down to the mouth of the jar and by slightly shaking the mass will fall out. This information comes to us through Mr. H. C. Worthen, general superintendent of the Western Union Telegraph Company at Atlanta, Ga., who no doubt considers it of value to those interested.

Radio-Telegraphy.

Long Distance Wireless.—A wireless message was transmitted from Glace Bay, N. S., to Dakar, Western Africa, on May 26, by way of the Eiffel Tower in Paris.

To Regulate Wireless.—The wireless telegraph companies are urging the passage of the bill now before Congress looking to federal regulation of wireless telegraphy in order to eliminate the present evils.

Wireless in South Africa.—The new wireless telegraph station erected by order of the Union Government of South Africa was opened on May 10. The station is situated at Slangkop, south of Cape Town.

Wireless Transmission from Flying Machine.—A former telegrapher named Parmalee, now an aviator, took a wireless outfit with him on one of his flights at Columbus, Ohio, recently and transmitted messages to the judge's stand.

Wireless Plant for the University of Michigan.—A wireless telegraph plant is being installed at the Michigan University, Ann Arbor, Mich. The plant is to be used for instruction purposes and will be operated in connection with the station at Ypsilanti.

Wireless Officials Convicted.—A verdict of guilty of misuse of the United States mails in a scheme to defraud was returned by the jury on May 29 against Col. C. C. Wilson, president of the United Wireless Telegraph Company, New York; W. A. Diboll, treasurer; F. X. Butler, counsel; G. W. Parker, western sales agent, and W. W. Tompkins of the eastern office. Wilson was sentenced to three years in the penitentiary, Parker and Butler to two years each and Tompkins and Diboll one year each. An appeal was taken on a writ of error. Mr. S. S. Bogart, vice-president of the company, was sentenced to pay a fine of $2,500.

How to Obtain Wireless Operator's Certificates.

In our issue of May 16 we printed the Wireless Ship Act which will go into effect July 1, and which provides that wireless operators on ships shall be required to pass an examination as to proficiency. Operators intending to qualify for such positions would be advancing their own interests by studying some reliable work on wireless telegraphy. An excellent book on this subject is Bishop's "Wireless Operators' Pocket Book of Information and Diagrams." The price of this book is $1.00 per copy and it may be obtained of Telegraph and Telephone Age, 253 Broadway, New York.

Wireless Stations of the World.—According to statistics published by the International Bureau of the World's Telegraph Union, there were 1,217 stations for wireless telegraphy at the beginning of 1911, as compared with 755 at the opening of the preceding year; 219 of the former were coastal stations, and 998 were stations on board ship. The United Kingdom is credited with the possession of the largest number, as represented by 450 stations; Germany ranks second with 224, and France third with 167 stations, all other countries combined only having 376, or less than the United Kingdom alone. The international agreement in regard to wireless telegraphy which was concluded in 1906, at Berlin, by twenty-seven countries, has been ratified by 20 of them. The countries which have not ratified the agreement are Argentina, Chile, Greece, Italy, Persia, Uruguay and the United States. Since the conclusion of the agreement accessions have been made by the inclusion of the Australian Federation, New Zealand, the South African Union, British India, and the remaining British Colonies and Protectorates with the exception of Newfoundland. A supplementary agreement has been made to the original treaty, but the former has not been accepted by Great Britain, Japan, Portugal, the French Colonies, Germany and the Dutch Indies.

Examination of Wireless Operators.

As showing the proficiency of the average wireless telegraph operator it is interesting to note that nearly everyone who has been called upon to take the government test at the Brooklyn Navy Yard has satisfactorily passed a rigid examination. Chief gunner W. H. F. Schluter, U. S. N., assistant to the officer in charge of the electrical class at the Navy Yard, is conducting the examinations. He is thoroughly competent, having been on duty with the class for about two years. The time required for the examination is from four to five hours. This would go to show that in a very short time a most efficient class of operators will be employed in the wireless service. Telegraphers who have not a good record for proficiency will under no circumstances be given a government license. The license is good for two years and is divided into three grades, i. e.: good, very good, and excellent. At the end of each two-year period the license must be renewed. It is hoped that the new national wireless law, which will go into effect July 1, will definitely determine the status of the wireless representative on board of vessels.

It is stated that 250 or 300 experimenters, or amateur operators, have applied to take the government examination, but the officials do not favor accepting their applications unless they bear a certificate from one of the wireless companies showing that they are actually in the employ of a company or seeking employment. This is no doubt done to protect the employes in the wireless service.

The examinations are held in the rooms of the Electrical Club at the Navy Yard on Tuesdays and Thursdays at 10 a. m. All the operator needs to take the examination is to present a letter from the company employing him or with which he seeks employment. The examination is open to all operators employed by or seeking employment by any wireless or steamship company, and this means shore as well as ship operators.

Locking Feature for Improved Buffalo Grip.

The Western Electric Company has recently placed on the market a new "Improved Buffalo Grip" with a special locking feature. In Fig. 1

FIG. 1.—BUFFALO GRIP WITH JAW HELD OPEN BY NEW LOCKING DEVICE.

the new grip is shown with the jaw held open by the locking device. A turn of the handle locks the jaw in any position and enables the lineman to easily and quickly insert the wire in the grip. When

FIG. 2.—GRIP CLOSED.

the handle is pushed down, as shown in Fig 2, the wire is held in a tight grip.

The "Improved Buffalo Grip" is made in various sizes for both bare and insulated wire, and can be supplied both with and without pulleys.

The Pueblo Southeastern Telegraph and Telephone Company has been incorporated at Denver, Col., with a capital stock of $50,000. The incorporators are W. D. Garwood, B. H. Talmadge and John H. Voorhees. This company is connected with the Pueblo Rockyford Land and Irrigation Company in the furtherance of its project of irrigation in the territory about Pueblo. A new town, named Wilson, has been established by the Irrigation Company, 16 miles from Pueblo, and is connected with Pueblo by the lines of the Pueblo Southeastern Telegraph and Telephone Company. At the present time there is a pole line of three wires throughout the Irrigation Company's property covering reservoirs, dams, etc. There is also a telephone line about 75 miles in length. A railroad is being built by the same interests between Pueblo and Wilson. The telephone lines are connected with the office of the Colorado Telephone Company.

Railway Telephony.

Apparatus to fill every requirement of railway telephone service is listed in bulletin No. 1080, "Railroad Telephone and Selective Apparatus," just issued by the Western Electric Company. The selector and selector set for local and common battery signaling are described in detail, and the advantages of the company's standard telephone and selective equipment are clearly stated. The bulletin contains fifty-six pages and lists, together with full information as to types and prices, a great variety of apparatus.

Selective Signaling.—"Absolute Safety by Selective Signaling" is the title of Bulletin No. 702 issued by the United States Electric Company, New York. It contains a history of signaling and goes into the modern practice at considerable detail. The Bulletin is well illustrated with artistically finished half tones of semaphore boxes and apparatus, circuit diagrams, etc., and is well worth the time of careful reading by any one interested.

Insulators. — The Brookfield Glass Company, New York, has just issued an attractive catalogue of its varied line of screw glass insulators and knobs for all purposes. It is illustrated with full size views of insulators, each illustration being accompanied by dimensions and other trade information. Glass knobs are also treated in the same manner. Mr. B. M. Downs, vice-president of this company, is well known to the telegraph fraternity.

Telephone Dispatching on Columbia and Puget Sound R. R.—The Columbia and Puget Sound Railroad has ordered from the Western Electric Company at Seattle, Wash., selectors and associated telephone apparatus for a circuit about thirty miles in length. The dispatcher for this line will be located at Seattle. Five way station telephone equipments will be installed. The line will be constructed of No. 10 gauge hard drawn copper wire.

Electrical Material for the Panama Canal.—The Isthmian Canal Commission is inviting proposals to furnish electrical material for use in the canal work for the year ending June 30, 1912. The material includes fittings, batteries, wire, cable, cross-arm pins, insulating material, etc. Those desiring to submit bids should address F. C. Boggs, captain, Corps of Engineers, U. S. A., General Purchasing Officer, Washington, D. C., naming circular No. 632.

War Experiences of a Telegrapher Shown in Pictures.—Mr. R. B. Griffin of Napa, Cal., an old-time telegrapher and member of the United States Military Telegraph Corps during the war, has published a story in book form in which he gives an account of his military telegraph experiences. A love story is interwoven in the narrative. The story is being illustrated for moving picture shows.

Dinner of the Commercial Managers Association of Greater New York.

The last of the Spring series of dinners of the Commercial Managers Association of New York of the Western Union Telegraph Company in Greater New York was held at the St. Denis Hotel, on Wednesday evening, June 7, and was a brilliant and successful function. The entire commercial forces of the company were present, including the lady managers in the city offices and the presence of the ladies aided materially in the great success of the occasion.

Mr. P. J. Casey, president of the association, acted as toastmaster.

Mr. Belvidere Brooks, general manager of the company, was the guest of honor, and seated at the guest table with him were Mr. E. M. Mulford, division commercial superintendent; Mr. W. N. Fashbaugh, traffic engineer; Mr. S. M. Williams, manager of the Commercial News Department; Mr. A. C. Kaufman, commercial agent of the Eastern Division; Mr. W. A. Sawyer, district commercial superintendent, First District; Mr. John A. Hill, division traffic superintendent; Messrs. D. Skelton and Thos. E. Fleming, of the American District Telegraph Company; Mr. M. W. Hamblin, special agent of the Metropolitan District; Mr. Wm. A. Porteous, manager at New Orleans, accompanied by Mrs. Porteous; Mr. B. H. Reynolds, superintendent of the Central and South American Cable Company; Mr. P. J. Casey, president of the organization, and Mr. J. F. Nathan, commercial superintendent.

The novel social feature of the evening was the successful carrying out of the duty imposed on every district commercial manager that all local managers and commercial forces in their territory should meet and become acquainted with the managers and forces in adjoining territories. The success of this plan was fully demonstrated in the hearty good fellowship which prevailed and remarkable for the fact that it seemed to overcome any trace of restraint or embarrassment, thus assuring to all present a most enjoyable evening. This duty devolved upon the district commercial managers, Messrs. John Simmonds, J. J. Riley, C. B. McCann, Frank Spree, M. J. Hayden, John Veitch, M. E. Pierce, P. Kinman, J. W. McMahon and J. T. Carberry. Mr. A. G. Saylor, general superintendent, was chairman of the reception committee, and was ably assisted by Misses M. E. Saunders, N. C. Loughlin, H. A. Samsony, A. Burns, A. Reed, H. B. Hoff, A. Lupka and M. Morrissey; Messrs. Frank Spree, M. J. Hayden, P. Kinman, C. B. McCann and J. T. Carberry, all of whom contributed greatly to the pleasure of the occasion.

At the conclusion of the dinner a recess was taken and a reception tendered Messrs. Brooks and Mulford. Both officials were introduced to every lady and gentleman present.

Mr. J. F. Nathan was the first speaker of the evening and his remarks upon "Co-operation in the Telegraph Service" were delivered in a manner befitting the speaker and the company he represents.

Mr. E. M. Mulford followed Mr. Nathan, his subject being "The Commercial Organization of the Eastern Division." Mr. Mulford spoke at length on the work accomplished and that under way and his remarks were enthusiastically received.

Mr. Belvidere Brooks, the next speaker, carefully reviewed the work being accomplished by the company and in his characteristic and genial way indicated the feeling of the corporation toward its employes, assuring them of his hearty personal interest in their welfare and his firm belief that it was the company's purpose to faithfully carry out the promises made. Mr. Brooks' happy manner and thought impressed all present most forcibly and his remarks were received with great enthusiasm.

Mr. S. M. Williams followed, and his address, "The Ladies and Their Essential Relation to the Telegraph," won all present. His clippings from the "Society Column" were unique and most original.

Mr. A. C. Kaufman spoke on the subject, "Concerted Effort Applied to the Telegraph," and spoke in his usual forcible and emphatic manner, assuring those present that it was the intention of the company to help them in every possible manner to overcome the obstacles which might confront them and that he would make it a part of his duty to give his personal aid to any and all who might ask it.

Mr. W. N. Fashbaugh was the next speaker. He pointed out that the traffic department stood ready at all times to assist the commercial department in accomplishing the aims they had in view.

Mr. W. A. Sawyer, when called upon, stated that he had come prepared to make a speech and that his only regret was the fact that he was so far down on the line that his speech had been all shot to pieces by the speakers who had preceded him. Consequently they had left nothing for him to say. He told how meetings of a similar character were being carried on all through the field; the relationship of these meetings to those of the New York Association, and the successful results that were being accomplished thereby.

Mr. W. A. Porteous, manager of the New Orleans office, expressed his pleasure at being present and with true Southern courtesy addressed his remarks principally to the ladies.

Mr. Thomas E. Fleming, of the Messenger Service Department of the company, was called upon for a few remarks, and acquitted himself in his usual resourceful fashion. His facetious replies to numerous quips levelled at him provoked much merriment.

Digitized by Google

Messrs. D. Skelton and B. H. Reynolds spoke briefly on matters connected with the service.

The meeting closed with an ode dedicated to the general manager and written for the occasion by "Jimmy" Felsenheld, attached to the commercial superintendent's office. It was well sung by Joseph Matier.

Following is a list of those present:

W. J. Ackerley, A. K. Ainlay, W. F. Alcock, A. Anson, Miss A. Antonius.

L. S. Badgley, S. Bollaban, Fred. Bollman, Miss Barry, C. A. Bauer, L. D. Beall, J. W. Behre, Miss Benson, B. F. Benson, Miss Bergman, J. A. Berry, J. A. Boland, J. S. Bradbury, Miss Brennan, C. J. Bresnan, M. J. Brooks, B. Brooks, R. Brown, Miss Browman, Miss E. Burke, Miss Burns, A. J. Burton, G. W. Blanchard.

J. Cahill, J. T. Carberry, Miss Casey, P. J. Casey, L. Cohen, Miss Corbett, F. E. Coyle, J. J. Cummings, Mrs. Curtis.

R. I. Dawson, A. Disney, Miss Donohue, Miss K. T. Donohue, D. Drew.

H. S. Earle, J. J. Earle, J. W. Egan.

W. N. Fashbaugh, N. Feder, Jas. D. Felsenheld, L. Fideldey, A. N. Fisher, J. Fleming, T. E. Fleming, T. F. Flynn, W. S. Fowler, D. Fuch.

R. F. Geissler, Miss Gerber, F. D. Giles, J. J. Gilroy, Jos. Goldstein, K. Goldman, Miss Gottschalk, M. M. Greene, P. E. Grogan, E. Guthrie.

S. Hackett, M. W. Hamblin, M. J. Hayden, C. A. Harvey, Miss Hayes, Miss Hecker, H. Herrmann, Miss Hills, E. G. Hohenstein, Miss H. B. Hoff, T. F. Hull, Miss Hyland.

N. W. Jacobs.

Miss Kaiser, Miss M. A. Kane, Miss N. Kailey, A. C. Kaufman, L. Kenny, A. L. Kaufman, Miss Kearney, Miss Kimball, Miss E. Kircher, P. Kinman, Mrs. S. K. Kirchbaum, J. Kistler, Miss E. Koch, F. J. Lantry, J. Lauermer, J. J. Lee, W. Levy, B. Liebowitz, A. Lister, Miss Loughlin, Miss Lougran, Miss Lupka, H. Lupka, D. Lynch, Miss Lyons, Miss Lyddy.

J. Matier, R. F. Martin, M. H. Megie, Miss Morrissey, E. M. Mulford, J. H. Murphy, R. F. Murphy, W. A. McAllister, C. B. McCann, Miss McEvily, J. P. McGovern, J. P. McGowan, J. J. McGrath, J. W. McMahon, Miss McNally, J. McNeil.

J. F. Nathan, E. B. Nieman, F. J. Nilan, R. J. Nimmons.

Miss O'Dea, Miss O'Donnell, Geo. Otten.

T. T. Parr, M. E. Pierce, Miss Pollak.

R. Raphael, Miss Reed, Sam'l Reiss, B. H. Reynolds, L. Ribler, M. J. Rivkind, J. J. Riley, Geo. Roehm, M. Russnow.

Miss H. Samsoney, Miss Samsoney, Miss Sands, Miss Saunders, W. A. Sawyer, Miss Scully, C. F. Seelman, W. H. Sembler, J. J. Shelley, Chas. E. Shelley, W. A. Schudt, A. D. Shaw, J. E. Shields, S. Silberstein, A. Simon, J. Simmonds, D. Skelton, V. M. Sozzi, Frank Spree, Miss Smith, Harvey Smith, Miss Stiles, Miss Stork, Miss Sullivan, P. J. Sullivan.

P. J. Tierney, F. Tevenan.

Miss Van Vleit, J. Veitch, M. P. Vrabel.

Miss Wagner, Miss Wall, L. A. Westrope, Miss White, O. L. Whitoneck, H. F. White, Miss Wilde, Miss Williams, S. M. Williams, J. N. Wintross, Miss Wocktell.

Miss Yorker.

O. Zilly, Miss Zimman.

Arrangements for Old Timers' Convention.

At a meeting held in Philadelphia on May 27 of members of the Old Time Telegraphers and Historical Association and of the Society of the United States Military Corps, the necessary arrangements were made and committees appointed to carry out the details of the joint convention of the two associations which will take place at Atlantic City on September 5, 6 and 7. Among those present were: Col. William Bender Wilson, president of both associations; Mr. F. J. Scherrer, secretary of the Old Timers'; Mr. Charles E. Bagley, vice-president of the Old Timers, and Messrs. J. W. Reed, J. A. McNichol, John Wintrup, G. W. Deetz, F. E. Maize and J. B. Taltavall.

Following is the programme agreed upon, subject of course to change:

Tuesday, September 5, morning, 10 o'clock.—Joint meeting in the convention hall of the Marlborough-Blenheim, called to order by the retiring president of the Old Time Telegraphers and Historical Association, Mr. W. J. Lloyd of Chicago; installation of the new president, Col. W. B. Wilson of Philadelphia; address of welcome and response; business meeting United States Military Telegraph Corps; business meeting Old Time Telegraphers and Historical Association; afternoon, roller chair parade; evening, concert and entertainment on Steel Pier.

Wednesday, September 6, morning.—Ocean sailing; afternoon, trolley party to Ocean City; evening, concert and theatre entertainment on Million Dollar Pier.

Thursday, September 7, morning—Ocean bathing; afternoon, go as you please; evening, banquet at the Hotel Shelburne.

The reception committee of the United States Military Telegraph Corps is composed as follows: Messrs. Jesse W. Crouse, chairman; Richard Graham, John Wintrup, Isaiah D. Maize, of Philadelphia; Henry H. Atwater, William L. Ives, George M. Huntington, Marion H. Kerner, Frank A. Stumm, Charles W. Pearson, Alfred Winder, Thomas T. Eckert, Jr., David H. Bates, Jr., Verdie J. Knittle, Albert Eckert Chandler, of New York, and Thomas Wallace Wilson, of Atlantic City, N. J.

Adapting Chinese Characters to the Telegraph.—The difficulties of adapting the Chinese language to the telegraph has always been a perplexity, but a solution to the problem seems to have been found by a Danish professor who has codified the 7,000 commonest Chinese characters representing them by numerals. Thus the Chinese word for "cash" is represented by the figures 6030.

Exhibitors and Representatives at the Boston Convention of Railway Telegraph Superintendents.

The various manufacturing and other companies interested in railway telegraphy and telephony will be represented at the Boston convention of the Association of Railway Telegraph Superintendents, June 26-30.

J. H. Bunnell & Co., New York, will be represented by Mr. J. J. Ghegan, president.

The Sandwich Electric Company, Sandwich, Ill., will be represented by Mr. H. O. Rugh and competent assistants.

Mr. W. E. Athearn, engineer of equipment of the Western Union Telegraph Company, will be at the convention to represent that company's interests.

The American Telephone and Telegraph Company, New York, will be represented by Messrs. B. A. Kaiser and G. W. Peck, of New York; Mr. Albert Douglass, of Chicago, and Mr. Henry Homer, of Philadelphia.

The American Typewriter Telegraph Company, New York, will give a practical demonstration of the Cardwell printing telegraph system on a wire from Boston to Providence and return. The company will be represented by Dr. G. A. Cardwell, the inventor of the apparatus and president of the company, and Mr. Willard M. Miner, electrical engineer.

The United States Electric Company, New York, will have its convention headquarters in parlor G on the main corridor of the Hotel Brunswick, and will have an exhibit of the Gill selector and other railway telephone dispatching appliances. Its train order and other signaling, based on absolute control by the dispatcher, will be demonstrated. The company will be represented by Mr. Charles Sigison, treasurer, and Mr. W. E. Harkness, assistant general manager, New York, and Mr. W. H. Cook, sales engineer, Chicago.

The Western Electric Company will have a complete display of railway telephone and selector equipment in parlor "E" of the Hotel Brunswick.

Here will be shown a working exhibit of selector equipment, as well as practically every kind of telephone apparatus used in the railway world. A feature of the exhibit will be the long life or endurance test which the Western Electric Company has been making on its No. 50 A selector. This selector has been put through over one and one-quarter million operations. This is equivalent to twenty-nine years of service, allowing ten calls per hour, twenty-four hours a day. The new semaphore which has recently been developed by the company will be in operation. This device combines a signal and telephone system and is sure to effect great operating economies in the handling of traffic. There will also be on exhibition transmitters and receivers, transmitter arms of various types, including the new Western Electric arm, desk stands, hand sets, jacks, plugs, keys, lightning arresters, protectors, condensers, retardation coils, line poles, blocking sets, test panels, battery boxes and line material. The new Western Electric group selector will be shown for the first time. The company will be represented by Messrs. G. K. Heyer, O. D. Street, E. A. Hawkins, J. L. McQuarrie, O. E. Stephens, R. F. Spamer, of the New York house; Mr. E. V. Adams, of the Chicago house, and Messrs. E. L. Hawkins, W. F. Abley and H. B. Gilmore, of the Boston house.

LETTERS FROM OUR AGENTS.

NEW YORK, POSTAL.

Mr. J. B. Havice has been appointed assistant chief operator days.

Mr. E. T. Ewing, day wire chief, has been transferred to a similar position on the night force, Mr. T. H. Tierney from the night force taking his place at the Eastern board.

NEW YORK, WESTERN UNION.

Mr. Martin Durivan, of this office, has resumed his position as chief operator at Long Branch, N. J.

Charles J. Lawson, aged 63 years, of this department, died suddenly on June 7. He was in the seventies night chief operator in the St. Louis office. He held many important positions in the telegraph service at other points and was attached to this office for the past thirty years, occupying the positions of operator, division chief, wire chief, etc.

Jacob Kline, who was employed as an operator in this office some years ago, died in Rochester, N. Y., June 6.

Milton Stephenson, formerly employed in this department, died at his home in Brooklyn, N. Y., on June 7. He will be remembered as a young man full of ambition and his manner endeared him to a host of friends. His father was the late R. G. Stephenson, who was general traffic chief in this office.

DALLAS, WESTERN UNION.

The Dallas office has grown rapidly in late years. We now occupy a large part of two floors in one of the principal buildings of Dallas and a large force of men is kept busy night and day handling the business.

Mr. W. B. Kendall, manager of the office, is a gentleman and highly efficient. His assistant is Mr. K. Stiles, who came from Chicago. The force is made up as follows: W. S. Strawbridge, chief operator; Roy Delay, night chief operator; H. P. Boni, wire chief; John B. Dillon, assistant wire chief; Al Lally, night wire chief; D. V. Snyder, repeater chief; J. J. McCormick, formerly of Chicago, repeater chief; David G. Lockwood, night repeater chief, succeeding Ora Downing, recently returned to Chicago; Gus Mansenerius, Aaron Roos, J. L. Laney, R. H. Loyd and B. H. Moody, traffic chiefs, and a large force of operators working under amicable relations with officials who are interested in the work and in the men employed to do the work.

Digitized by Google

Mr. Laney is one of the oldest members of the force in point of service. His entire business career has been spent in the employ of the Western Union Company.

LOS ANGELES, WESTERN UNION.

Mr. T. W. Carroll, assistant to the general manager, New York, was a recent visitor at Los Angeles.

Two more stories have been added to the Western Union office building on Spring Street below Sixth. On the fifth floor a telephone switchboard has been installed to accommodate this branch of the business, pneumatic tubes running thence to the operating room.

PHILADELPHIA, POSTAL.

Messrs. C. P. Bruch, third vice-president, E. B. Pillsbury, general superintendent, and M. M. Davis, electrical engineer, of New York, and H. A. Tuttle, president of the North American Telegraph Company, Minneapolis, Minn., were recent visitors at this office.

Mr. L. L. Howell, supervisor of traffic, was here for several days looking over the traffic situation.

Mr. J. M. Eder spent several days in Atlantic City overhauling the quads there for use during the summer rush.

A new Keystone Telephone Exchange has been installed which will greatly increase our already rapid telephone delivery of messages.

The continued warm weather has caused the business to take a jump, especially in the Delaware, Maryland and Virginia produce district.

RICHMOND, VA., WESTERN UNION.

On June 2 eleven members of the Western Union operating department at Richmond, Va., met and organized the "Western Union Electrical Club of Richmond." Officers were elected and a systematic course of study was planned. The particular object of the club is to advance the educational attainments of its members from a technical standpoint, but other phases of the telegraph, such as traffic conditions, etc., will be discussed. At the second meeting fifteen members were present and it is expected that the membership will continue to grow. The meetings are held every Tuesday night. A great deal of interest has been manifested, the men showing by their attendance that they are willing and glad to have an opportunity to more thoroughly and fully study this phase of the telegraph business.

The great telegraphic song hit,
"SEND ME A NIGHT LETTER, DEARIE."
Good, catchy music; beautiful title design magnificently printed in colors. Title contains night letter. Sung all over New York, 17c. by mail. All popular music sent by mail.
B. L. BRANNAN,
195 B'way, N. Y.

TUCSON, WESTERN UNION.

Reconstruction of the Western Union circuits in and out of Tucson, Ariz., has been completed. All poles, wires and connections are now in first-class condition. The recent insurrecto activities along the Mexican border have more or less delayed business to Mexico.

The local office was recently inspected by assistant to the general manager, T. W. Carroll, of New York, and District Commercial Superintendent Hugh McPhee and District Plant Superintendent L. Messner of Los Angeles, who were well pleased with the up-to-date conditions and service found here. These officials visited the ancient San Xavier Mission near Tucson while in the city.

Martin's Double Lever **VIBROPLEX,** $8.00 f. o. b. D. C. DeLany, 15 S. Broad St., Atlanta, Ga.

FOR SALE—A Bunnell galvanometer, complete in leather case, with resistance coils and connections for Wheatstone bridge measurements. Must be disposed of immediately to close an estate. Cost over $100.00. Will sell for $35.00. Address "Galvanometer," care Telegraph and Telephone Age, New York.

The Telegraphers' Mutual Benefit Association, 195 Broadway, New York, enables telegraph and telephone employes to provide for their families life insurance in reasonable amounts, at a cost so low as to be within the reach of all. It has already paid beneficiaries of deceased members $1,500,000, at an average annual cost per $1,000 of about four cents a day, and has also accumulated $327,000 Reserve Fund securely invested, to provide against excessive cost in the future. Membership is easily acquired and cannot be invalidated during life for any cause except failure to pay the necessary mortuary calls.

TRANSMITTING MACHINES

I am placing on the market improved YETMAN TRANSMITTING TYPEWRITERS, and KEYBOARD TRANSMITTERS without typewriting features. Am prepared to exchange, repair or rebuild all old machines. Write for catalogues and particulars to

James Uncles, NORTH ADAMS Massachusetts

Rubber Telegraph Key Knobs.

No operator who has had to use a hard key knob continuously should fail to possess one of these flexible rubber key caps, which fits snugly over the hard rubber key knob, forming an air cushion. They render the touch smooth and the manipulation of the key much easier. Price, fifteen cents.

SOME POINTS ON ELECTRICITY.

BY WILLIS H. JONES.

THE FIRST DYNAMO.

Probably the best way to obtain a thorough knowledge of the construction and the principles involved in the operation of any finished industrial device is to go back and follow the inventor throughout his first experiments.

By this method one not only gets the true idea of the conception, purpose, and basic principles which govern the construction of the modern machine, but the facts are so impressed on the mind by the things that happened or did not happen when such experiments were made that they are never forgotten.

For example, let us take a dynamo. The student is told that a dynamo generates electricity by the rotation of a coil of wire in a magnetic field in such a manner that the wires of the coil cut the magnetic lines of force and the faster they cut the lines per second or the greater number cut per revolution, the greater is the E. M. F. developed. Of course, the student admits the facts, as he can readily see that such is the case. Yet after all it is only an assertion so far as he is concerned. He does not quite understand why, and for that reason must turn to his textboook and reread the definition several times before he can remember it. In other words, the logic of it has not been impressed on his mind.

If now he will go back and follow Faraday during his experimental days, note how he happened to think of developing electricity by mechanical means, and particularly note the failures he made before finally solving the problem, he will see the reason for every particular point of design or construction of a modern machine. Nor will he ever have to refer to the textbook again for the definition. Each feature of the machine will remind the student of "first principles."

Now let us go back to about the year 1830. At that time Oersted had made what was then considered one of the greatest discoveries in electricity, viz.: that magnetism could be created by

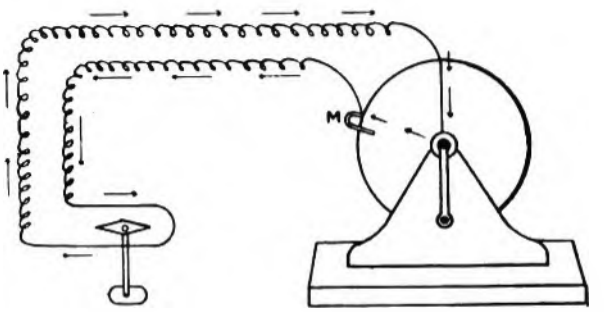

DIAGRAM OF THE FIRST DYNAMO.

an electric current. It was not long after this discovery that one or two scientists had thought it just possible that the tables might be turned, and a current created by magnetism. But no one had succeeded in bringing about that result. Faraday in 1831 after many tedious experiments finally succeeded and the crude machine he constructed, which is roughly shown in the accompanying illustration, constituted the first dynamo that was ever built. Before describing it let us follow Faraday's first experiments.

He knew to begin with that magnetism and an electric current were inseparable companions; therefore he concluded that if he placed a second wire in the magnetic field surrounding the first wire which carried a current, he should be able to detect a secondary current in wire No. 2. In this conclusion he was correct, but he had a hard time in proving it. Every now and then he would get a spasmodic deflection of the galvanometer needle placed in wire No. 2, but it immediately dropped to zero and thus constantly baffled his efforts. He now had proof that current did actually develop in the secondary circuit, but as yet did not know how or why. Finally after many ex-

Digitized by Google

periments he noticed that these deflections never occurred except just at the moment he made the connections or disconnected them. The trouble was he at first did not look at the needle until he had made all the connections, when of course it was too late.

As soon as he learned that the current in wire No. 2 flowed only at the instant of "make" and again at "break," he was as puzzled about the action as ever.

After pondering over the phenomenon a long time he remembered that a current of electricity in a wire requires a certain fraction of time to rise to its full volume, and also to fall to zero, and hence concluded that the magnetism may have developed and receded in step with it. From this he got the idea that the alterations in the strength of the magnetic field, which naturally occurred only at the moment of "make" and "break," were the real cause of the secondary current, and that it also explained why no current flowed in the secondary after the current in wire No. 1 was fully established.

To verify these conclusions he then took an ordinary permanent steel magnet, in no way connected with an electric current, and placed his coil, or wire No. 2 containing the galvanometer, near the polepieces, or in other words in the magnet's own field. It required only a few minutes to learn, what we all now know to be a fact, that current will flow in the coil as long as the coil is kept moving either to or from the polepieces of the magnet, but will not flow if you stop. Everything was now plain sailing. He saw that the current was due to continued alterations occurring in the number of magnetic lines of force flowing through the coil because he knew that the density of the lines in the magnetic field was different at any two points between which the coil might be moved. He also noted that it required mechanical energy to move the coil back and forward, although in this case he used his hand. Thus he obtained the first idea of constructing a machine that would convert mechanical energy into electrical energy and at the same time proved to the world that magnetism could also be made to produce an electric current.

A glance at the illustration will show the manner in which the "baby dynamo," as it was called, was constructed and operated.

Between the polepieces of a strong steel magnet he rotated a large copper disc by means of a crank after the manner of an ordinary grindstone. Two brushes were attached to this disc, one pressed on the axis and the other on the circumference, while a galvanometer was connected in circuit, the terminals of which were connected with the two brushes as shown.

When the disc was rotated rapidly it cut through the lines of force and the resulting E. M. F. developed at that point caused a current of electricity to travel across the circumference to the other brush where it was carried off to the galvanometer via the wire connected to the companion brush.

Of course this machine developed a very feeble current, but it contained all the principles employed in modern machines, viz.: the magnetic field, the rotating armature, the two brushes, and means of rotating the armature.

Modern machines furnish a stronger magnetic field, because they are electro-magnets energized by electric currents. The armatures create more E. M. F. because coils of low resistance replace the copper disc and can be rotated faster and in a much stronger field.

The student should study the "baby dynamo" carefully and then compare each part thereof with the corresponding parts in the modern machine. Note the difference in the construction and ask "why."

Recent Telegraph and Telephone Patents.

ISSUED JUNE 6.

994,302. Telephone System. To H. P. Clausen, Chicago, Ill.

994,361. Method of Propagating Telephonic Currents. To C. G. Ashley, Chicago, Ill.

994,371. Individual Selective Lock-Out Device for Party-Line Telephone Systems. To W. M. Bruce, Jr., Springfield, Ohio.

994,426. Receiver for Wireless Telegraphy. To R. H. Rendahl, Berlin, Germany.

994,500. Selective System for Party-Line Telephones. To. W. M. Bruce, Jr., Springfield, Ohio.

ISSUED JUNE 13.

994,719. Telephone System. To H. P. Clausen, Chicago, Ill.

995,339. Space Telegraphy. To L. De Forest, New York.

Personal.

Mrs. L. J. Brant, wife of the late John Brant, secretary of the Old Time Telegraphers' and Historical Association, New York, will spend the summer months with friends in New York State.

Miss Camille Carvin Sheppard, daughter of Mr. W. A. Sheppard, manager of the Western Union office at Montgomery, Ala., was married to Mr. Oscar Brannen Ogletree on June 28.

Mr. Will Y. Ellett superintendent of fire alarm telegraph, Elmira, N. Y., was a recent New York visitor and took occasion to call on many of his New York friends while in the city.

Mr. A. Phillip, an official of the Poulsen Wireless Telegraph and Telephone Company, Copenhagen, Denmark, was in San Francisco recently in connection with the extension of his company's service.

Mr. P. W. Drew, superintendent of telegraph of the Minneapolis, St. Paul & Sault Ste. Marie Railway, Chicago, and secretary of the Association of Railway Telegraph Superintendents, was a recent New York visitor. He was accompanied by Mrs. Drew.

Digitized by Google

Miss Julia Sullivan, a telegraph operator at Great Barrington, Mass., attended the coronation of King George and Queen Mary of England on June 22, as a guest of one of her Massachusetts friends.

George Maynard, son of Mr. G. C. Maynard, of Washington, D. C., a well-known forty-niner of the telegraph, was awarded the prize for excellence in spelling at the recent commencement excercises of Cheshire School, Cheshire, Conn. He was also awarded honorable mention for general scholarship.

Mr. Fred. Allen, formerly an operator for the Postal Telegraph-Cable Company at Washington, D. C., and late of the Waldorf-Astoria Hotel, New York, has accepted the position of assistant manager of the Hotel Marie Antoinette, New York. Mr. Allen is a son of Mr. W. H. Allen, former manager of the Postal office at Washington, D. C., and now private secretary to Fourth Assistant Postmaster-General P. V. DeGraw.

Mr. Frank C. Mason, formerly superintendent of police telegraph, Brooklyn, N. Y., entertained a class from the Arcanum Club at his country home, Glen Alex Farm, Washington Mills, N. Y., recently. A lunch was served and games were indulged in. Mr. F. E. Howell, manager of the Western Union Telegraph office at Utica, N. Y., won the first prize for broad jumping and Messrs. McIntyre and Wells, former operators, participated in the quoits contest. The prizes were donated by Mr. Mason.

Postal Telegraph-Cable Company.

EXECUTIVE OFFICES.

Mr. Theo. L. Cuyler, Jr., assistant treasurer of this company, is enjoying a well-earned vacation in Connecticut.

Mr. C. H. Walters, assistant cashier of the New York office has been appointed division cashier, and Mr. W. V. Stahl has been promoted from the auditor's office to succeed Mr. Walters as assistant cashier.

Mr. C. E. Bagley, district superintendent, Philadelphia, Pa., was a recent executive office visitor.

Mr. H. Scrivens, district superintendent, Pittsburg, Pa., is spending a vacation at Chautauqua, N. Y. During his absence Mr. Leona Lemon, division superintendent, New York is looking after affairs in Mr. Scrivens' district.

Mr. A. B. Parrish, division cashier, New York, has been transferred to the general manager's office.

Mr. Charles M. Wilgus has been appointed manager of the Galveston, Tex., office of the Postal Telegraph Company of Texas, vice Fred. A. Rollfing.

Mr. Frank S. Gould, manager of the Postal office at Grand Rapids, Mich., has been advanced to the managership of the Detroit office of the same company, vice B. F. Ramsdell, transferred to Chicago.

Mr. J. F. Heard, electrical inspector of this company, Atlanta, Ga., and Mr. F. N. Andrews of the Birmingham, Ala., office were recent New York business visitors. Both gentlemen called on numerous friends while in this city. Mr. Andrews is an old New Yorker, having been employed in this city in the eighties. He has been a resident of Birmingham for the past eighteen years.

The Mackay Telegraph and Cable Company opened its Dallas, Tex., office June 22.

The Postal Telegraph Cable Company has leased considerable additional space on the eleventh floor of its building in Chicago, to better meet the needs of the increasing business.

Mr. Frank S. Gould, manager of the Detroit, Mich., office of the Postal Telegraph-Cable Company, was born in Philadelphia, Jefferson Co., N. Y., October 3, 1870, and entered the telegraph service at Grand Rapids, Mich., June 1, 1887. For several years afterwards he worked as operator on various railroads in the Northwest. His commercial service began with the Western Union Company at Lacrosse, Wis., afterwards going to Fargo, N. D. Later he went to Duluth for the North American Telegraph Company and afterwards with the United Press and the Associated Press. On April 1, 1900, he became manager of the Grand Rapids, Mich., office of the Postal Telegraph-Cable Company, which position he held at the time of his appointment to the managership of the Detroit office.

Western Union Telegraph Company.

EXECUTIVE OFFICES.

Mr. E. J. Hall, chairman of the executive committee of this company, is spending the summer in cruising around the waters about New York in his schooner yacht *Latona*.

Mr. Belvidere Brooks, general manager, attended the commencement exercises at Williams College, Williamstown, Mass., from which his son Bruce has just graduated.

Mr. Wm. H. Baker, vice-president of the American District Telegraph Company of New Jersey, is enjoying a short vacation for the benefit of his health.

Mr. T. W. Carroll, assistant to the general manager, has returned from his inspection trip to the Pacific Coast after an absence of six weeks.

Mr. A. G. Saylor, general superintendent, New York, has returned from a trip to Philadelphia and Washington.

Mr. E. M. Mulford, division commercial superintendent, New York, spent a few days recently in Pittsburg on company business.

Mr. George M. Yorke, engineer of the company has established his office in the room adjoining that of Mr. W. N. Fashbaugh, traffic engineer, on the fourth floor.

Digitized by Google

Mr. Charles B. Dunham manager of the Canso, N. S., office of the Western Union Telegraph Company, has been transferred to the Bay Roberts, N. F., station of the same company. In August this year Mr. Dunham will have been in the employ of the company for half a century. He entered the service of the old American Telegraph Company at St. John, N. B., as messenger in August, 1861, and became an operator in 1863. He was appointed manager of the Canso cable station in March, 1882, and has been there ever since until his transfer to Bay Roberts.

Mr. T. C. Harlan, has been appointed manager of the Western Union Telegraph office, at Lake Geneva, Wis.

Mr. Chas. M. Holmes, who has just been appointed manager of the Western Union Telegraph Company at Jacksonville, Fla., was born in Monroe, Wis., in 1860. He first entered the telegraph service as a messenger at Atlanta, Ga., in 1871, having studied telegraphy during school vacation. He graduated from school at the age of fourteen years and went to Wisconsin where he entered the railroad service. In 1883 he went to Kansas City, Mo., and afterward entered the employ of the Postal Telegraph-Cable Company which was then building its lines through that part of the country. Two years later he became connected with the Atchison, Topeka and Santa Fe Railroad, becoming finally the head of a department in the auditor's office at Los Angeles, Cal. Later he was train dispatcher of the Southern Pacific Railroad and in 1900 entered the Western Union service, becoming manager at Bakersfield and Sacramento, Cal., and Bisbee, Ariz., successively. He was afterwards employed in the Salt Lake City office and from there was transferred to Jacksonville, Fla., in January this year. He was appointed district commercial manager for Florida and Alabama and on May 15, received the appointment of manager at Jacksonville. During his busy career Mr. Holmes has found time to study law and is a graduate of a law college, holding the degree of B. L. He is a member of the Old Time Telegraphers' Association.

Mr. A. B. Robinson, night chief operator of the Western Union office at Wilmington, N. C., has been promoted to the managership of the Charlottesville, Va., office of the same company.

Morse Electric Club Outing.—The summer outing of the Morse Electric Club will be held at Donnelly's Boulevard Hotel, College Point, L. I., N. Y., Saturday, July 8. The Western Union Telegraph Company has placed its steamer at the disposal of the club for the purpose of conveying the members and guests to and from the hotel grounds. There will be an attractive and enjoyable entertainment programme. Athletic events and a game of baseball will be features of the occasion. Tickets can be obtained of Mr. R. J. Murphy, treasurer, 195 Broadway, New York, at $1.50 each.

Conference of Pittsburg District Commercial Managers and Managers.

A conference of district commercial managers and managers of the third district, Eastern Division, Western Union Telegraph Company, was held at the Fort Pitt Hotel, Pittsburg, Pa., June 22. At the meeting papers were read as follows: "Co-operation," by G. F. Stadtmiller, district commercial manager; "The Company's Relations to the Public," by E. R. Collins, district commercial manager; "Courtesy," by G. S. Walters, district commercial manager; "The Value of Organized Messenger Service," by Earl Burton, district supervisor of messenger service; "What Efficient Traffic Means to the Commercial Department," by N. E. Church, commercial superintendent; "Systematic Solicitation," by S. C. Moran, solicitor; "Explanation of Form 219-A," by C. E. Furick, cashier. The two sessions were presided over by Mr. A. C. Terry, district commercial superintendent, Pittsburg.

There were thirty-five district commercial managers and managers present. Mr. E. M. Mulford, division commercial superintendent, Mr. J. A. Hill, division superintendent of traffic, and Mr. A. C. Kaufman, commercial agent, all of New York, were also in attendance. Much interest was manifested in the papers read and they were attentively listened to.

In the evening a dinner was served at the Fort Pitt Hotel at which there were thirty-three seated at the tables. After the dinner appropriate remarks were made by Messrs. E. M. Mulford, J. A. Hill, A. C. Kaufman and A. C. Terry, who presided.

An interesting feature of the afternoon session was the effort made by Solicitor S. C. Moran, of the Pittsburg office, to induce Mr. Terry, who assumed the rôle of principal in an important firm of commission merchants, and his chief clerk, (Mr. Kaufman), to give their telegraph business to the Western Union Telegraph Company. The dialogue between these three continued for nearly an hour to the interest and amusement of the managers present.

District Commercial Superintendent Terry has decided to hold tri-annual conferences at which all district commercial managers and managers will be in attendance. He will also confer with the five district commercial managers at Pittsburg monthly.

Those present were: Mr. E. M. Mulford, division commercial superintendent; Mr. J. A. Hill, division superintendent of traffic; Mr. A. C. Kaufman, commercial agent, New York.

District commercial managers: V. E. Church, E. R. Collens, Pittsburg; G. S. Walters, Clarkesburg, W. Va.; G. F. Stadtmiller, Jamestown, N. Y.; H. King, Charlestown, W. Va.

Managers: H. Young, Wheeling, W. Va.; I. N. Sharpnack, Parkersburg, W. Va.; C. H. Reed, Huntington, W. Va.; J. W. Barbee, Charlestown, W. Va.; U. W. Boggess, Clarkesburg, W. Va.;

Digitized by Google

M. N. Haller, Elkins, W. Va.; W. T. McWhorter, Fairmont, W. Va.; S. W. Kirk, Johnstown, Pa.; J. L. Snyder, Cumberland, Md.; H. Trent, Bluefield, W. Va.; J. F. Callahan, New Castle, Pa.; J. C. McGrew, Erie, Pa.; M. F. Horne, New Kensington, Pa.; L. J. Ward, Pittsburg, Pa.; T. J. Jones, Pittsburg, Pa.; G. F. Harris, Ridgway, Pa.; F. W. Clark, Sharon, Pa.; E. E. Buel, Bradford, Pa.; Jos. W. Barbee, Butler, Pa.; A. A. Jeunet, Franklin, Pa.

Solicitors: S. C. Moran, Pittsburg; Geo. Blair, Pittsburg; J. A. Javens, Pittsburg.

Municipal Electricians.

Mr. William B. Martin, assistant superintendent of the Albany, N. Y., fire alarm bureau, has been promoted to be superintendent.

Automatic Fire Alarm.—Mr. H. Becker, of Newport, Ky., has been granted a patent on an automatic fire alarm.

Thermostat Patents.—Mr. M. J. Briggs, of Philadelphia, Pa., has been granted two patents (Nos. 992,541 and 992,542) on a thermostat.

Break-Glass Fire Alarm.—A patent has been issued to C. Auth, New York, on a break-glass fire alarm.

Fire Alarm Extensions at Richmond.—New fire alarm boxes and police telegraph signal equipment have been installed in Richmond, Va., under the supervision of Superintendent Wm. H. Thompson.

Fire and Burglar Alarms.—Patents have been issued to H. G. Perkins and G. H. Elliott, of Topeka, Kan., on a fire alarm; to J. M. Johnson, of Belleville, Kan., on a burglar and fire alarm system, and to J. W. Mobray, of Gleichen, Alberta, Can., on a thermal electric fire alarm.

Fire Alarm System in Kansas City.—The 173 police call boxes in Kansas City, Mo., have been fitted with fire alarm devices and it is now possible for a policeman or pedestrian upon the discovery of a fire to send in an alarm without hunting up a telephone. One hundred more street poles will be fitted out with police and fire alarm boxes. Ultimately it is intended to install red electric globes on each pole, to be flashed when the police stations wish to communicate with the policeman on the beat.

Canadian Notes.

Mr. A. E. Starr has been appointed acting manager of the Victoria, B. C., office of the Canadian Pacific Railway Company's Telegraphs, vice Mr. William Christie granted an extended leave of absence. Mr. Christie is one of the best known of old timers and before his entering the Canadian Pacific service some twenty years ago was well known in telegraph circles in the United States. He entered the service of the Dominion Telegraph Company in 1880 and soon became an operator. He was in Texas for the benefit of his health between 1882 and 1884 and in December of the latter year he returned to Victoria, becoming manager of the office in 1891.

Racing News Stopped in Montreal.—The Montreal police authorities recently cut the wires between the Bluebonnet race track and the city, thus preventing the sending of the results of the races to newspapers. It is alleged that the pool rooms were getting the benefit of the newspaper information.

The Railroad.

Train Dispatchers Convention.—The twenty-fourth annual convention of the Train Dispatchers Association of North America was held in Baltimore, Md., June 20. There was a large attendance of members from the United States, Canada and Mexico.

Telephone Train Dispatching in Oregon.—The Oregon-Washington Railroad and Navigation Company has ordered of the Western Electric Company telephone train dispatching equipment for a circuit from Portland, Ore., to The Dalles, Ore., a distance of ninety miles. This circuit will be equipped with seventeen stations.

Telephone Train Dispatching on the Pennsylvania.—The telephone system of train dispatching is used on 2,530 miles of track, both single and double, on the Pennsylvania Railroad. At present the company has under construction 293 miles. The total mileage of the road is 5,558. Mr. J. C. Johnson, Philadelphia, Pa., is superintendent of telegraph. This information was received too late to be included in the statistical table published in our issue of June 16.

Meeting of Railway Signal Association.—The Railway Signal Association met at the Astor Hotel, New York, June 13 and 14. A letter was read by secretary C. C. Rosenberg regarding the fund for the proposed monument at Turner, N. Y., to commemorate the first telegraphic train order. The various committees of the association made reports, and trips of inspections were made to the different railroad yards in the city. A paper on Apparatus for charging storage batteries was read and discussed.

The Telephone.

Mr. A. R. Skinker of the traffic department of the American Telephone and Telegraph Company, New, York, has been appointed supervisor of traffic of the fourth division for the same company at Chicago, Ill.

Mr. W. D. Hanchette, formerly manager of the Western Union Telegraph Company at Watertown, N. Y., and now and for many years past identified with the telephone service at Albany, N. Y., is the author of an article in *The Telephone Review* for May entitled "The Introduction of the

Digitized by Google

Telephone into the North Country—A Chronicle of the Early Days of Telephony in New York State." It is an interesting story and Mr. Hanchette was associated in this early work with Mr. W. B. Eddy who was then manager of the Whitehall, N. Y., office of the Western Union Telegraph Company and now manager of the commercial department of the New York Telephone Company at Albany, N. Y.

Telephone Conference in Texas.—Commercial managers of the Southwestern Telegraph and Telephone Company met in conference recently in Galveston, Tex. Among those present were Mr. H. J. Pettengill, president; Mr. J. E. Farnsworth, vice-president and general manager; Mr. P. K. Baker, general commercial superintendent, and a number of other officials. Representatives from various independent companies also attended the meeting.

Telephony in England and America.—Mr. T. F. Purves, one of the four officials of the British postoffice who recently investigated the telephone service in the United States, states that the service in the large towns of America is distinctly smarter than in England; and since his return "the local London service has seemed more irritatingly slow than it did before." The average delay before a trunk connection can be obtained in England is not much greater than in America, except between large cities, where the superiority of the American trunk service is indisputable, the trunk lines being far more numerous; at the same time, the cost of a trunk call is correspondingly greater there.

Telephone Language in England. — The language of the telephone in London is different to that in America. For instance, there the operators say the line is "engaged"; here we say it is "busy." The Englishman is not so impolite as to say "Hello!" when trying to get some one on the telephone. He says "Are you there?" He is, however, adopting the terser American expression. Toll lines are called "trunks" in England, and the public asks for trunks instead of "long distance" wires. Lines between two exchanges are called "junction wires," and when one desires to have the person at the other end hold the wire, he says, "Will you please hold on?"

New Telephone Stock.—At a meeting in Boston on June 20 of the directors of the American Telephone and Telegraph Company it was voted to authorize an issue of approximately $50,000,000 of new stock, in the ratio of one share of new for each five of old. Rights attach as of June 30 and expire August 31. The proceeds of this issue of capital stock will be mainly used to provide the associated companies of the Bell system outside of the State of New York with funds for current and ordinary construction and extension of plant, and will be represented in the treasury of the American Telephone and Telegraph Company by the share capital or the capital advance notes of such companies. A part will be used for extensions to the plant (long-distance service) of the American Telephone and Telegraph Company outside of the State of New York, and a part to maintain the cash balances now being drawn upon for all the above purposes.

Radio-Telegraphy.

Wireless in New Zealand.—The New Zealand government proposes to erect a high-power wireless telegraph station on the Tinakori Hills behind Wellington.

Wireless Distress Call on Lake Erie. — The steamer *Western States* was disabled on Lake Erie recently and wireless distress signals were sent out from the crippled boat. The steamer *City of Cleveland* received the signals and went to the rescue, taking aboard the 225 passengers from the *Western States*.

Receivers Appointed for United Wireless Company. — Messrs. Sidney Harris and Robert E. Dowling have been appointed by Supreme Court Justice Cohalan as receivers for the United Wireless Telegraph Company, New York, four of whose officials are under sentence for violating the United States postal laws.

Train Control by Wireless. — Hertzian waves have been applied to the operation of an automatic train stop and cab signal invented by Mr. Frank W. Prentice who has been conducting experiments with the system on the Canadian Pacific Railway near Toronto, Ont., during the past year. Mr. Prentice is now turning the apparatus over to the railway company.

Obituary.

Thomas F. Kennedy, aged 45 years, for several years operator at the Maritime Exchange, New York, died June 15.

Mrs. Joe Hansen, wife of the late Col. Joe Hansen of St. Louis, Mo., whose death at Hot Springs, Ark., was announced in our issue for June 16, died at St. Joseph, Mo., June 18, less than one month after the death of her husband.

The Late Thomas Langdon.—Thomas Langdon, a well-known telegrapher in the West and Northwest, whose death was announced in our issue of June 1, was a member of the Society of the United States Military Telegraph Corps. He was in the military telegraph service during the last year or two of the civil war. He had a wide acquaintance in the South and West and was connected with early railroad building in Minnesota after the war. For several years afterwards he filled positions in many of the more important Western Union offices in the South, West and Northwest.

Death of William Richard Brixey.

We regret to note the death at Seymour, Conn., of Mr. W. R. Brixey, one of the leading manufacturers in the field of insulated wire and cables. He was born at Southampton, England, May 11, 1851, educated at a well known grammar school and then entered the British Mercantile Marine service commanding his own ship and visiting all the leading ports of the world. He came to this country in 1878, becoming at once an American citizen, and went into business with his brother-in-law, Mr. A. G. Day, a pioneer in the American rubber industry and the inventor of Kerite. In 1879 he married Miss Francis N. DeWolfe, daughter of Alva G. DeWolfe, a coworker of Mr. Day and also an inventor of some note. The Day plant was at Seymour, Conn., and there Mr. Brixey developed the business with remarkable energy and intelligence, mastering it in every detail and becoming general manager

THE LATE W. R. BRIXEY.

on the death of Mr. Day, and sole proprietor upon the death of his sister, Mrs. Day.

Mr. Brixey was not satisfied with the use of his cables in the telegraph and telephone field or with the early endorsement of such men as Morse, but pushed out into larger developments in other fields. Some of the most noteworthy of these included the supplying and laying of the Alaskan cable, the furnishing of the Panama zone cable, and the furnishing of the wires and cables for the Pennsylvania tunnel and terminal connecting the two shores of the Hudson and East Rivers.

In 1908 Mr. Brixey incorporated the business as a company and soon after retired, leaving it to the management of his eldest son, Mr, Richard D. Brixey, president of the Kerite Insulated Wire & Cable Company. Mr. Brixey left two other sons, Mr. Reginald W. Brixey, vice-president, and Mr. Austin D. Brixey, secretary of the company.

Mr. Brixey was quite active in public life, being a member of the American Institute of Electrical Engineers, and a member for many years of the Old Guard of New York City with the rank of captain. He was a member of the Brooklyn Club and a high degree Mason. At the time of the terrible subway explosion at Murray Hill, New York, in 1902, he was very seriously injured by glass blown into his room at the adjacent hotel. His wonderful constitution, however, pulled him through injuries of a most serious character, though these probably undermined his health, which had always been of the best.

Mr. Brixey's wife died in 1909 and he is survived only by the three sons named. Mr. Brixey was a man of sterling qualities and of unusual generosity. His death will be sincerely regretted by all who knew him.

Death of F. N. Bassett.

Frederic N. Bassett, for many years a prominent figure in telegraph and newspaper circles in New York, died at Washington, D. C., June 20. Deceased was born in Connecticut January 22, 1853, and began his telegraphic career in 1870 as an operator for the Western Union Company in New Haven, Conn. Two years later he came to New York and worked at 145 Broadway. In 1875 he accepted a position with the Associated Press at Washington and was one of the eight famous operators who manned the first leased wire of the Associated Press, between New York and Washington. He was appointed private secretary to Postmaster-General T. L. James in 1880, and on the retirement of Mr. James he became chief clerk of the post-office department. In 1883 he became post-office inspector, but returned to newspaper work in New York in 1887, afterward becoming general eastern manager of the United Press in New York and later of the combined United and Associated Press. After the failure of this concern in 1897 Mr. Bassett engaged in various lines of business, but in late years his health was not of the best.

QUESTIONS TO BE ANSWERED.

[The success which has attended our plan of publishing in each issue a list of questions covering the subjects considered in Jones' Diagrams, has encouraged us to maintain the work through other books. Students of telegraphy throughout the country are finding these questions of great assistance in their studies of the general principles underlying the operation of the apparatus with which they come in daily contact. Many consider this the best plan which has yet been devised for a systematic study of the technical side of the telegraph. Having completely covered Mr. Jones' book we are now covering "The Quadruplex," by Maver and Davis, and will bring out, in a like manner, all the facts that every telegrapher should know about duplex and quadruplex telegraphy as found in this book.]

CHAPTER IV.

How is the transmitter of a Stearns Duplex worked?

How is the relay wound?

Digitized by Google

What are the resistance coils or rheostats used for?

What are the condensers used for in connection with a duplex?

Referring to Fig. 19, how does the current from battery F pass through the relay R?

With the connections as shown, what effect does the current from battery F produce upon the relay R?

What effect has the same current on relay R' at the other end of the line?

What is the effect of closing transmitter T', as shown in the illustration?

With the transmitter T' closed how are the currents divided between the coils of relay R'?

Describe what takes place if the transmitter be now opened?

On which relay does battery F have active effect?

Which battery operates relay R?

Why does a line wire act like a condenser?

What happens when the battery is cut off from the line and a path to ground is substituted?

What factors cause a variation in the line discharge?

What is the ordinary term used to indicate the line discharge?

What is the difference in the effects of discharges on short and long circuits?

What is the condenser used for?

How is it connected to the relay?

What is the effect upon the line discharge upon the condenser discharge?

Why are coils Q and Q' used, and what should be the value of their resistances?

CHAPTER V.

Referring to Figs. 8 and 9 how is the magnetic polarity of the iron bar determined?

What is the magnetic effect of charging the direction of winding of the coils on the bar?

What is the rule for determining the polarity of a bar magnet?

How does the current flow on the line when the wire is connected to the positive pole of the battery?

How does it flow when the wire is connected to the negative pole?

What would be the effect of placing to the line the positive poles of equal batteries at each end?

Study the effects of reversing the direction of current through the relay coils as shown in Figs. 22 and 23.

What is an electro-magnet?

Study the construction of the polar relay shown in Fig. 24.

Why is the permanent magnet curved as shown?

Why do the pole pieces of the electro-magnet of a polar relay face each other?

Would this relay work if the permanent magnet were removed, the other parts remaining unchanged?

Western Union Earnings.—The report of the Western Union Telegraph Company for the quarter ending June 30 shows a decrease in net profits of $335,000. President Theo. N. Vail stated that while the net earnings for the year would show a decrease the gross will be in excess of the previous year.

Wooden Leg as a Life Preserver.—Those unfortunates who are compelled to use wooden legs as a means of propulsion now have cause to rejoice thereat. It has been demonstrated that wooden legs make excellent life preservers under favorable conditions. An operator in the West, with a wooden leg, was in a row boat with four companions when the boat capsized and threw them into the water. The man with the wooden leg could not swim but his leg could float and it is due to this fact that his life was saved. His companions located his position amid the waves by the bobbing up and down of the wooden leg and went to his rescue.

Constantinople Telephone System.—Reference was made in a recent issue of this paper to the proposed introduction of the telephone in Constantinople by English engineers. A staff of engineers is now in Constantinople to make a telephonic survey of the city and to prepare plans and specifications for the system, which is to have an original capacity of 10,000 lines, and to be ready to start service in July, 1913. As no telephone service yet exists in Turkey, all modern facilities having been debarred by the ex-Sultan, there are no available data whereby to gauge the probable use of the service or the probable traffic which the system will be called upon to carry. The peculiar composition of the population of Constantinople, makes the business part of the engineering study one of much complexity. Three languages are current—Turkish, Greek and French—while many more are spoken, and the variety of local customs and practices is probably greater than in any other large city in the world. The Telephone Development Company, Ltd., has been formed for the purpose of carrying on the necessary work, pending the organization of the Ottoman Telephone Company, which will construct the plant and operate the service.

Handbooks for Artisans and Experimenters.—Spon & Chamberlain, New York, one of the oldest firms in the world publishing technical books, produce a series of practical hand books for amateurs and students who are interested in experimental work. The list shows a great variety of subjects covered by these books, not only in the electrical line but in mechanics as well, and the price per copy is low enough to permit any one of limited means to acquire a general understanding of the practical construction of electrical and mechanical apparatus. The list of publications is a long and interesting one and the firm will send descriptive lists free to any one interested.

Telegraph and Telephone Age

Entered as second-class matter, December 27, 1909, at the Post-Office at New York, N. Y., under the act of March 3, 1879.

Published on the 1st and 16th of every month.

TERMS OF SUBSCRIPTION.

One Copy, One Year, in the United States, Mexico, Cuba, Porto Rico and the Philippine Islands . $2.00
Canada 2.50
Other Foreign Countries 3.00

ADDRESS ALL COMMUNICATIONS TO
J. B. TALTAVALL, - Editor and Publisher
253 BROADWAY, NEW YORK.
T. R. TALTAVALL, Associate Editor.

CABLE ADDRESS: "Telegage," New York.
Telephone: 6657 Barclay

CHANGES OF ADDRESS.—In ordering a change of address the old as well as the new address must be given.
REMITTANCES to Telegraph and Telephone Age should be made invariably by draft on New York, postal or express money-order, and never by cash loosely enclosed in an envelope. By the latter method money is liable to be lost, and if so remitted is at the risk of the sender.

July 1, 1911.

The Boston Convention of Railway Telegraph Superintendents.

The Boston Convention of the Association of Railway Telegraph Superintendents this week was a highly successful one from every point of view. The papers presented were on the whole of extraordinary quality and the discussions ensuing brought out much valuable information on subjects of direct and related interest.

One thing noticeable at the meeting of this association is the intense interest shown by the members in matters that are in the line of improvement in railway operation, and the eagerness with which they seize upon anything of promise shows that they are progressive and alive to the interests they represent.

Telephone train dispatching naturally received considerable attention and much information of value to all concerned was developed in the discussions on this important subject. It is not many years ago that the members shook their heads doubtfully at the suggestion that the telephone could be used for train dispatching; now, there is not one who does not shake his head the other way. This simply emphasizes the care that should be exercised in judging or forming opinions on matters that we or others have not submitted to a practical test. No man's opinion is worth anything if not supported by facts.

Can New Telegraph Business Be Created?

The experience with the day and night letter service has brought to light some interesting facts. It has proved among other things how sensitive the telegraph business is and how readily it adjusts itself to changed conditions. When the night letter service was introduced the cheaper rates had the effect of robbing the day service of some business, thus, to some extent nullifying the object intended, i. e., to keep the wires utilized during dull periods. As much of the business that was usually transacted during the day time was, under the new order of things, deferred to the night service by reason of the lower rates, it left a gap in the day business that had to be filled in.

This condition gave rise to the day letter service and how successfully the latter has accomplished its purpose has not yet been announced by the company conducting it. The object of the company is evidently to keep its plant in use as many of the twenty-four hours per day as possible. This, of course, is a correct principle, but in order to attain this end there should be business enough to keep the lines busy. But, it has been argued, there is not enough traffic to do this. Granting this, the only thing to do is to create new business and this seems to be the task that the company has undertaken. How far it will succeed no one yet knows. Opinion seems to be sharply divided on that point. On the one hand it is asserted that the general public cannot be induced to use the telegraph any more than it does now, while on the other it is claimed that considerable new business has actually been created. The company's agents are making an active campaign and are said to be meeting with much success in interesting the general public in the telegraph and thus creating new traffic. No doubt there are thousands of persons who could be secured as new or more liberal patrons of the telegraph were its advantages pointed out to them in a proper manner. This part of the service requires very skilfull and intelligent handling, however, and the company must be prepared to render first-class service and thus please the new customers in order to retain their business.

Viewed in whatever light, the problems confronting the telegraph company are highly interesting and the results are being watched with the deepest interest.

How to Use the Telephone.

That the telephone is an instrument of great utility is generally conceded but it is questionable whether an instrument of any kind in general use is so much misused. Perhaps not one person in three speaks into the transmitter properly and it is surprising that the telephone works as well as it does under such adverse circumstances. Many people seem to have the idea that if the mouthpiece of the transmitter is pointed towards them that it is all that is necessary for proper transmission, the question of proximity of the lips to the mouthpiece being unthought of.

We have heard of instances where telephones have been ordered discontinued and removed by irate subscribers on the ground that they would not work, and on proper investigation by the company's inspectors it was found that the fault lay wholly with the subscribers in not knowing how to talk into the transmitter.

In railroad telephone work such misuse of the instrument is so common as to require special in-

Digitized by Google

structions by some railroad companies for its correction. In the excellent article published in our issue of June 16 on "Current Practice in Rules for Telephone Train Dispatching," the author, Mr. John W. Barney, refers incidentally to this matter and calls attention to the importance of speaking into the mouthpiece in a proper manner. The advice given there should be carefully followed on all railroads because it concerns a matter of vital importance, involving, as it does, the safety of the lives of passengers.

Popularizing the Telegraph in Belgium.

The Belgium postal authorities have inaugurated for internal communication a system of telegraphic subscriptions, by means of which newspapers, business houses and any persons who, while making daily use of the telegraph, do not wish to rent a private wire, are enabled to transmit their messages at about one-half of the ordinary rates. The only conditions attached to the system, which Belgium is said to be the first country to adopt, are that a minimum number of 250 words per day shall be paid for, and that the messages shall be transmitted between stated hours. The Belgium government is now desirous of obtaining the consent of Great Britain, France and Germany, in order that a similar system may be established between Belgium and those countries.

Proposed Telegraph Tournament for 1912.

The advisability of holding a telegraph tournament in the southern states in 1912 has been suggested. The last tournament held in that section was Atlanta, Ga., on March 1, 1902, and was participated in by many of the most expert operators in the United States. Contestants came from Chicago, St. Louis, Denver, San Francisco, Kansas City, New York, Washington, Philadelphia, and many southern points.

About $2,000 in money prizes was distributed, as well as prizes from typewriter companies, and Mr. Andrew Carnegie gave a handsome gold medal studded with a large diamond valued at about $500 to be awarded to the best all around telegrapher. This it will be remembered was won by Mr. Fred. M. McClintic and later lost to Mr. Wm. M. Gibson of New York, the present holder. Mr. Carnegie provided that the medal should be contested for from time to time and passed to the winner.

It is nearly ten years since the Atlanta tournament took place and it has been suggested to us by Mr. H. Van Devender, commercial superintendent of the Western Union Telegraph Company at New Orleans, La., that that city would be a good place for the meeting of the next tournament. He thinks that some time in February, 1912, just before the Mardi Gras festival in New Orleans, would be an advantageous time. Railroad fares on all lines to that city will then be reduced on account of the festival and this would likely ensure a large representation from the various sections of the country.

New Orleans is suggested on account of the advantages to be obtained at this time, but there are other southern cities that might be considered as equally available for the contest, including Dallas, Tex., Memphis, Tenn., Atlanta, Ga., Nashville, Tenn., etc., and no doubt any one of them would be willing to undertake the responsibility attaching to such an enterprise.

It is hoped that sufficient enthusiasm will be aroused to ensure another contest of skill in the near future.

The Delights of a Shipwreck.

Mr. Reid G. Ford, the wireless operator on Mr. E. C. Benedict's yacht *Virginia* which went ashore near Havana recently states that it was "the most delightful wreck I have ever known or read about."

He thus describes the "delights" of the wreck:

"We were," said he, "grounded at a spot where the coral bottom could be seen through the clear, still water. Fishes of all colors swam all around us. Most of the morning was spent by those on board in fishing.

"At midday the *Virginia Daily Telegram* was issued. This was my work. The news was made up of little incidents of the day and all we picked up by wireless. A good deal of this was about ourselves and the plight of the vessel.

"In the evenings we had concerts, at which Prof. Henry Rowe Shelley performed.

"The weather seemed made to order, and everybody had a good time until they were taken to Havana by the wrecking steamer a week after the wreck occurred."

Mr. Ford's experience was certainly a delightful one but it should not be assumed by inexperienced wireless mariners that the lot of wireless operators on ships is cast in such pleasant places.

A Thorn in the Western Union Flesh.—Because a woman in New York thought she was unjustly charged 15 cents for the delivery of a telegram by the Western Union Telegraph Company, she complained to the Public Service Commission and the company has been requested to answer the charge. The company's lawyers will be compelled to go to Albany to explain matters. It costs money sometimes to defend a principle, and in this case the telegraph company will be obliged to go to a considerable expense on account of a wrathy woman, who insists that she has a claim of 15 cents damages against that corporation.

Control of Public Utilities in District of Columbia.—A bill has been introduced in the Senate at Washington providing for a public utilities commission for the District of Columbia. The bill gives the commission full powers to supervise and regulate the operation of all public utilities in the District, including telegraph and telephone companies.

Mr. Tesla's 1,000,000 Horsepower Wireless Telephone.

In a lecture before the New York Section of the National Electric Light Association, New York, on May 15, Mr. Nikola Tesla, the noted inventor, told of many things he expected to do by the use of wireless electrical power.

"I have annihilated distance in my scheme," he said, "and when perfected it will not be one mite different than my present plans call for. The air will be my medium, and I will be able to transmit energy of any amount to any place in the world. I will also be able to send messages to all parts of the world, and I will send words out into the world which will come out of the ground in the Sahara Desert with such force that they can be heard for fifteen miles around.

"I also hope to set up a central wireless telephone station whereby there will be a force of 1,000,000-horse power behind each word uttered into my instrument, and in which distance will play no hindrances whatever. Many hundreds of people will be able to talk at the same time and without any interference with each other."

Mr. Tesla says he has perfected a new steam engine for aeroplanes. A ten horse-power engine will weigh one pound.

Wireless Operator's Pocketbook of Information.

The Wireless Operator's Pocketbook of Information and Diagrams, is the title of a 174-page book just off the press. The author is Leon W. Bishop, a well-known authority on wireless matters, and he has given to the student and general reader a book that is well worth careful reading and study. It is a practical pocketbook for the wireless operator, showing all up-to-date apparatus, in theory and practice. Its purpose is to satisfy the desires of the wireless operator and of those experimenters who have already some knowledge of wireless phenomena, for a practical book more suited to their needs than the many elementary ones which deal mostly with the construction of simple apparatus, or the elaborate technical and mathematical treatises which presuppose a technical education to understand them.

Briefly, it thoroughly describes all transmitting and receiving instruments; aerials, giving the types and relative sizes for the best work in transmitting and receiving; the latest methods of tuning both transmitting and receiving apparatus; and it has a full chapter of diagrams, showing the most improved circuits for all sizes and sets, both in transmitting and receiving.

Among other features it gives a table showing how to compute roughly the sending and receiving distances for all types of instruments with all types of aerials and ends with the latest Call-Book containing the calls of the principal land and water-stations in America both government and commercial. A prominent authority on wireless telegraphy states that this is the best book on the subject he has ever seen, and he has purchased them all. The book is very liberally illustrated and the price is $1.00, $1.25 or $1.50, according to the style of binding, which is in cloth, leatherette and leather, respectively. Postage and insurance of safe delivery are 10 cents additional.

This and other books on electrical subjects can be supplied by J. B. Taltavall, Publisher, 253 Broadway, New York.

Extending Canadian Government Telegraph Lines.—The Dominion Parliament has voted to build new telegraph lines and reconstruct existing lines in the northwest section of Canada.

Public Service in Florida.—A bill has been introduced in the Florida Senate to extend the powers of the railroad commission so as to give it authority to regulate charges of telegraph companies in that state.

Forgery of Money Transfers.—Four men were recently indicted in Washington, D. C., on charges of forgery and conspiracy growing out of the securing of $465 from the Western Union Telegraph Company on alleged bogus money transfer telegrams.

A Youthful Wireless Inventor.—W. E. D. Stokes, Jr., of New York, 12 years of age and a wireless amateur, has, it is stated, invented a "receiving box" by which he reproduces the words and sounds in a wireless telephone loud enough to be heard several feet from the instrument.

Wire Thieves.—The Postal Telegraph-Cable Company has suffered the loss of considerable copper wire recently in the vicinity of Chicago. In one instance three miles of wire was carried off. The Western Union Company and the Chicago Telephone Company have also sustained considerable loss of wire.

Decision Against Loan Sharks.—The war against money lenders on salaries is being prosecuted vigorously. The Appellate division of the Supreme Court at New York has decided that no money may be collected from the employer of a salaried borrower unless notice is given to the employer at the time the money is advanced.

Telephone Rates in Pennsylvania.—The Pennsylvania State Railroad Commission, in passing upon a case involving telephone rates, decided that the practice of the respondent in giving certain periods of free telephone service in consideration of contracts for a longer period of service at the standard rates, is illegal and unlawfully discriminatory, and it is, therefore, recommended that said practice be forthwith discontinued and abandoned.

What is Thought of Telegraph and Telephone Age.

Mr. E. A. Chenery, superintendent of telegraph, Missouri Pacific Railroad, St. Louis, Mo., writes: "The Age is read with much regularity and oftimes with greater pleasure than some of my mail, and is essentially necessary."

Mr. S. B. McMichael, superintendent of the Dominion Messenger and Signal Company, Toronto, Ont., writes: "You did quite right in renewing my subscription, as I would not care to have your valuable paper discontinued under any circumstances."

Mr. W. T. Capen, general superintendent of plant of the Postal Telegraph-Cable Company, New York, in renewing his subscription for another year, writes: "Enclosed please find my check for the purpose of renewing my subscription to my old friend 'Age,' which is the most welcome periodical I receive."

Mr. E. Boening, district commercial superintendent of the Western Union Telegraph Company, Seattle, Wash., writes: "Your action in renewing my subscription for the TELEGRAPH AND TELEPHONE AGE meets with my hearty approval. I take pleasure in enclosing check for $2.00 covering the same."

Mr. E. J. Little, superintendent of telegraph of the Great Northern Railway Company, St. Paul, Minn., in renewing his subscription for another year, writes: "I will be very glad to have you renew my subscription each year, as I consider the Age one of the most complete telegraph and telephone journals published."

Mr. W. F. Williams, superintendent of telegraph of the Seaboard Air Line Railway, Portsmouth, Va., writes: "I thank you very much for having renewed my subscription. Please understand, I wish this done as long as I am able to pay for it. We could not very well get along without the AGE."

Mr. W. P. Cline, superintendent of telegraph of the Atlantic Coast Line, Wilmington, N. C., writes: "To say that the TELEGRAPH AND TELEPHONE AGE is indispensable would be trite and to say that I look forward to its arrival with eagerness, would be to repeat what many others have told you; but, as between lovers, the old story is new, I pass it on you."

An old friend of TELEGRAPH AND TELEPHONE AGE in renewing his subscription writes: "Your wrapper said my subscription expired. That is not so. It expires when I do and not before. Never saw perpetual motion, eh? Listen. My subscription is that same thing. The Age and I are pals. Don't interfere with the perpetuity. Keep it coming and draw on me for the annual dues."

Mr. A. W. Orton, an old-time and military telegrapher, now in the lumber business at Rome, N. Y., writes: "I always take pleasure in recommending the Age to those who are now connected with the telegraph or telephone work, for if one whose interest is in other lines of business finds something that is of value and interest in every number, certainly the employe who wishes to keep abreast with the advances in electricity ought to get great value from the knowledge to be derived from Telegraph and Telephone Age."

Mr. M. H. H. Duvall, of the firm of Goodwin, Duvall & Co., brokers, Augusta, Ga., in renewing his subscription, says: "Of course your action in renewing my subscription meets with my approval as well as my thanks. Telegraph and Telephone Age is always a welcome visitor to my office. I believe all of the old timers are interested in matters pertaining to the service in which many of us spent the best years of our lives and your paper affords the best medium of keeping us in touch on such matters as well as with many dear friends of former days."

Mr. W. C. Burton, civil service commissioner at Brooklyn, N. Y., and a former well-known telegrapher, in renewing his subscription for another year, writes: "I take pleasure in sending you herewith a renewal of my subscription to TELEGRAPH AND TELEPHONE AGE. The paper is a welcome visitor and commands my prompt attention and eager interest. It keeps me informed concerning the wonderful present-day development of telegraph and telephone, and gladdens my heart by its frequent announcement of the advancement of old friends and of the introduction of new and broader policies for the improvement of the lot of the rank and file."

New Book on Storage Batteries.

Storage Batteries: Their Theory, Construction and Use. By A. E. Watson. Second edition. Price, $1.50.

This excellent work has been completely revised and enlarged and brought up to date. The author is assistant professor of physics in Brown University, Providence, R. I., and the manner in which he has treated his subject shows that he is thoroughly familiar with it. The contents are descriptive and general, and there are no mathematics whatever to confuse anyone not familiar with algebra.

The book contains chapters on the construction of plates, the action of the lead storage battery, how to make a storage battery, disease and remedies of the storage battery, boosters, etc., and gives much information valuable to anyone interested.

This book or any other on electrical and kindred subjects may be obtained of Telegraph and Telephone Age, 253 Broadway, New York.

Subscribe for Telegraph and Telephone Age. It is the leading paper of its class in America.

Digitized by Google

Multum in Parvo.

BY J. S. KNAPP, BUFFALO, N. Y.

Apropos of the many and various improvements being inaugurated by the telegraph companies, not only for the benefit of the public service but also for the welfare of the employes, I deem it proper at this time to express some thoughts that have come to me in the direction of progress. "Many trifles make perfection, and perfection is no trifle," is the one principle that should govern the telegraph business.

All telegraph blanks for received messages should be of the size of the Western Union Company's form 2138, which measures 7 x 8 inches. The size will not inconvenience the public and will avoid the delay in traffic while an operator is securing a "long" blank on which to copy a 75 or 100-word telegram. Frequently an operator is required to use one or more of the smaller blanks fastened together to accomplish what could be done more easily by using the 7 x 8 blank.

The same blank should be used for relay messages and city messages. It is annoying and useless for an operator to be compelled to say "city" and "thru" when sending to one office, while the next office he may send to uses only one form.

Everything should be standardized. I have found no two offices in the United States that used the same system of handling business. This is obviously wrong. I find that in at least two offices in Texas the local blanks are composed of two sheets held together by a perforated line, the lower blank bearing no printing. A carbon sheet is placed between the two blanks to make the office copy, thus doing away with the old water-copy method. This form of blank is a nuisance and a source of delay because it keeps an operator busy removing the carbon sheets from each message as he receives it, and seeing that his blanks are all "loaded" for work. Frequently he gets his carbon between the blanks with the carbon on the wrong side which causes another delay while he re-copies the message. Of course this will not happen when a two-sided carbon sheet is employed. Sheets with only one side carboned are generally used, however.

Again, an operator will "sit in" upon a heavy wire with a lot of these "books" made up and some evil-minded or perhaps jocular fellow-operator will come along and purloin them. This causes more avoidable delay.

Imagine the strain upon any operator working a fast bonus wire trying to do good work by being hampered with this style of blank, which also frequently feeds poorly through a typewriter!

Another point which has been overlooked is the various ways in which the service notations and "time" are placed upon messages by the operators. This should be standardized also. When an operator is sending a message he should first write the number of the message, the distant office call, the sender's signal, the receiver's signal and last and most important, the actual time of sending, thus:

"301 CH. WD. BM. 10:30 p.m.,"

not

"CH. 301 WD. 10:30 p.m. BM."

In case a letter is used with a number to designate a second or third wire, the letter should precede the number, thus:

"B 301 CH. WD. BM. 10:30 p.m."

It is not necessary to dilate further upon this idea; it speaks for itself.

Next comes the form of a received message. The same rule should obtain in this case, with the exception of the time, which should always be written after the signature, either at the right or left side of the blank, at least one line space below the signature. However, it should be noted that a recent ruling omits the sender's signal.

Improper handling of back date messages should also be considered. A message filed at the counter at 11:55 p.m., June 1, for instance, and sent by an operator at 12:01 June 2, should bear the notation: "2nd" immediately after the time, thus, for example: "12:01 a.m., 2nd."

In receiving the same message the receiving operator should always affix the receiving date "2nd" after he has placed the time at the lower side of the message. A message should be handled in strictly proper form in this respect, and I believe in severely reprimanding any failures upon the part of operators who do not adhere to this important point.

When a message requires more than one sheet, each sheet should be as carefully marked as to service and time as the first sheet, either in sending or receiving, breaking if necessary to do this. In sending a back date message, the operator should be compelled to say: "1 dx 2," and not leave it for the receiver who through lapse of memory may have forgotten what day of the week it is.

Finally, I have always made it a point when transmitting a message to send a period after the last word in the body and one after the signature, for the following reasons: Suppose the last word in a message should be "box," "car," "piano," etc., and the sender sends it something like this: "Car-sig John Smith," it confuses the receiver so that he is required to wait to see if the last word ends with the letter "s," or whether the "s" is the first letter of the "Sig." Frequently, also, the words "box," "car," "piano," etc., may be written in the plural and a receiving operator must be wide awake to know what to do in cases of this kind, if the sender does not use periods as suggested. A period before and after the signature is a wonderful help and guards against mistakes. Operators frequently send messages winding up with the signature, omitting the period and then wait a moment or two before starting another message, with the result that the receiver has it something like this: (Sig) "George H. Smith," and thinking

Digitized by Google

the message complete has allowed it to be taken away. He, of course, is greatly annoyed and traffic is delayed when the sender, before starting another message, says: "Sig. George H. Smith & Co."

I believe that all serious minded persons in the telegraph service will agree that the foregoing suggestions would, if adopted, be a benefit to employers, employes and the public alike.

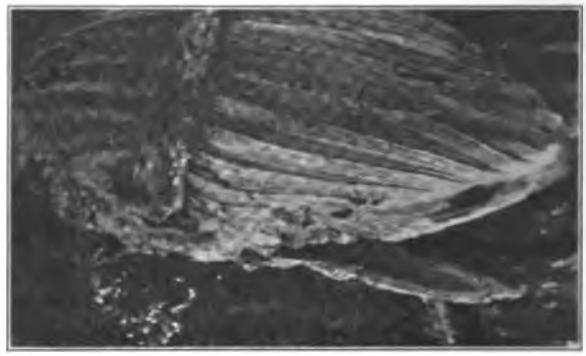
Telegraph Staff of the Santa Fe at Topeka.

The accompanying illustration, from the May number of the *Santa Fe Employes Magazine*, shows the general-office telegraph staff of the Atchison, Topeka and Santa Fe Railroad at Topeka, Kan. Mr. L. M. Jones, superintendent of telegraph, occupies the fourth seat from the left in the front row, and he may well feel proud of his staff of intelligent-looking assistants. They are all young men and women, full of life and hustle, such as is needed on a progressive railroad. There are forty-three men and five women in the group.

TOPEKA TELEGRAPH STAFF OF ATCHISON, TOPEKA AND SANTA FE RAILROAD.

Cable Broken by a Whale.

The accompanying illustration shows a peculiar accident to the Alaskan cable of the War Department between Sitka and Valdez. A whale, evidently feeding, caught the cable in its mouth and in its efforts to free itself threw a loop of the cable around its lower jaw. Not being able to clear itself of the entanglement it drowned, in the meantime having damaged the cable so that it had to be repaired. The cause of the break in the cable was not suspected until repairs were being effected, when the carcass of the whale in an advanced stage of decomposition was hauled to the surface with the cable. The core of the cable was pinched and partly broken between the armor wires by the struggles of the whale. Eight of the eleven armor wires were broken in the twisted portion near the whale's jaw, and it required skillful handling to prevent breaking the cable and losing the end.



CARCASS OF WHALE ENTANGLED WITH CABLE.

The photograph and the facts relating to this unusual occurrence were supplied to us by Brigadier-General James Allen, Chief Signal Officer of the United States Army, Washington, D. C., and by Mr. David Lynch of New York, who was government electrician in charge of the repair work.

Pollak-Virag System of Telegraphy in France.—It was recently reported that the Pollak-Virag system of telegraphy was being used in France by the government for press transmission, but inquiry proves that this is not the case. The Minister of Public Works, Posts and Telegraphs for the French government informs us that the Pollak-Virag apparatus is not used by the Administration. The trial was made between private newspaper offices outside of all control of the Administration, which limited itself to put telephonic circuits at the disposition of the interested parties.

TELEGRAPH AND TELEPHONE AGE is the leading paper in these two fields and is progressive and newsy. Subscription price, $2 00 per year.

Hard-Drawn Copper Wire.*

BY THOMAS B. DOOLITTLE.

In the fall of 1877, while acting as an agent for the Bell Telephone Company, I received an order from the Ansonia Brass & Copper Company to connect its office and mills by telephone. Samuel Cotter was the general superintendent of the mills. To him I addressed myself, stating that I wished to build those lines of copper wire and to have the wire drawn under my own direction. I well remember his reply: "You can build them of gold if you want to." Thereupon he accompanied me to the wire mill, where he instructed the superintendent to detail a man to do whatever I required.

The problem (if it could be solved at all) was to draw a rod of given size (or number) down to a wire of given size (or number) without annealing, and in this way to produce a wire with the proper tensile strength and ductility. A rod of Lake Superior copper was procured and the experiment began. After repeated trials with rods of different sizes and by the use of many "holes" or dies, in order not to crystallize or granulate the metal by too much strain, the desired result was accomplished, but not until after many trials in which we found the finished product either too brittle or too soft.

It is an interesting fact that drawing the wire eleven numbers produced the result then, and today the hard-drawn copper for line purposes is referred to by the manufacturer as "eleven numbers hard." Although the product is known to the trade as hard-drawn copper wire, and properly so known, as the name indicates its property of hardness and the method of manufacture, the name has no contra term, because soft-drawn copper would be a misnomer. The very process of drawing eliminates the quality of softness and makes it hard.

Previous to the introduction of hard-drawn copper wire much thought and large sums of money had been expended to get the benefit of the superior conductivity of copper for electric line conductors. The first recorded employment of copper wire as a line conductor was its use by Professor Morse in his experimental line between Baltimore and Washington. The ordinary market wire was used, but for the reason that it would not sustain its own weight it was abandoned and iron wire was substituted.

The next on record was strung by the Western Union Telegraph Company in New Jersey. In this case also the ordinary copper wire was used. This proved unsatisfactory and was taken down. An attempt was made to increase the tensile strength by doubling and twisting it. This was done and the wire was put up again. It was still unsatisfactory and was again taken down.

In another experiment steel wire was used with a copper ribbon wound spirally about it. In another case the copper ribbon was folded longitudinally about the steel wire. In another the copper was electroplated on the steel wire. This latter was adopted by the American Rapid Telegraph Company on all of its lines and was manufactured by Wallace & Sons in Ansonia, Conn.

This went the way of all the others for the reason that a chemical action was set up between the steel and copper which destroyed the steel. There were many other and equally futile attempts along the same line. It is to be admitted that the advent of the telephone created a great demand for electric conductors of high conductivity, but it is unaccountable, when we consider the amount of money that had previously been expended and the amount of work that engineers and inventors had given to the subject, that it had occurred to no one to avail themselves of the simplest possible thing—hard-drawn copper wire.

The work of connecting the several mills, offices, and residences of the officials of the brass company was carried on to completion, all lines being of hard-drawn copper. A switchboard was placed in the office of the brass mill and placed in charge of Charles A. Cotter, son of the general superintendent. This was, undoubtedly, the first private-branch exchange in the world.

A portion of the wires in the Bridgeport exchange were of hard-drawn copper and these continued in service for seventeen years, or until they were displaced by underground cable. The wire showed no deterioration. I had the greatest difficulty in trying to introduce this wire. I urged it upon several companies, including the Western Union Telegraph Company. At last I secured the promise of a company to make tests of it, provided the wire could be furnished at the cost of iron. I made the proposition to the Ansonia company without success. One day I met Col. Fred Mason, president of the Bridgeport Brass Company, who said to me:

"Doolittle, there should be something in the telephone field that would interest us."

"There is," I replied, "but you wire people have no sand."

"What do you mean?" said he.

"You will not do what I ask," I replied.

"Now wait: I will do anything you ask," he said. "Now, go ahead."

I explained that I wished him to furnish a given amount of hard-drawn copper wire at the price of iron, pound for pound.

"I will do it," he said. "Send in your order."

I immediately went to the manager of the telephone company and made arrangements for him to send in his order. I went on a long business trip and when I returned was informed that the wire had been strung. I went to the place to see it and make a test and found, much to my surprise and disgust, that they had strung common market wire, cotton covered. They said in explanation that, it being an experiment, they had ordered cotton covered wire so that, if it proved a failure, it could be taken down and used for inside wiring. Of course it proved a failure. The first rain soaked the cotton and the whole line sagged.

In another case I had almost persuaded the management of a company to string a metallic circuit

*Abstract from New England Telephone Topics.

Digitized by Google

of copper wire between two important cities, but at last they weakened and, instead of that, they strung a number four iron with a ground circuit. The unusual size and conductivity of this wire only served to increase the induction to a point where it was almost impossible to talk over it.

The objections to hard-drawn copper, without any investigation whatsoever, were of many kinds. That it was too costly; that it would stretch and sag; that it would not stand exposure to the elements; that the structure of the metal was impaired by the process of drawing; that the conductivity was reduced to a point where it would be little, if any, better than iron; that it would be stolen, etc. The most amusing objection was that it would expand from heat of the sun, and not contract to normal when cool. Some one said that if this was the case, it was foolish to draw the wire, for it would only be necessary to lay a rod of copper wire out into the sun. Then with a few hot days and cool nights it would draw itself.

Finally the subject was brought to the attention of Mr. Theodore N. Vail, then general manager of the American Bell Telephone Company. He, with his usual comprehensive grasp of things, authorized me to build a metallic circuit of hard-drawn copper wire between New York and Boston. When Mr. Vail inquired of me regarding the manufacture of the wire, I related to him the experience of Colonel Fred Mason of the Bridgeport Brass Company, and explained to him that his company was loser some hundreds of dollars, and that it would be only fair to give them the contract.

Mr. Vail asked me to send for Colonel Mason, which I did, and a contract was made with him, specifying that the wire should be drawn under my personal supervision.

In December, 1877, I sent samples of the first hard-drawn copper that was made to Boston for tests. After a year of exposure I sent another sample. In February, 1881, at the request of Thomas A. Watson, engineer of the Bell Telephone Company, I made a report on the condition of the wire and forwarded samples of both the old and new wire. My report was referred to Mr. Vail, who instructed Dr. W. W. Jaques, electrician, to make a test of the wire for conductivity, as compared with soft-copper wire, and also as compared with iron wire, and as well with the new hard-drawn copper wire that had not been in service. There was shown to be no perceptible deterioration in any way.

The production of the wire having waited for the man with knowledge of the subject and its application, so its development awaited a man with financial backing, ability and broad comprehension of its possibilities.

Accordingly, in 1883, six years after hard-drawn copper wire had been in constant and absolutely successful service, general manager Theodore N. Vail commissioned me to build a metallic circuit of No. 12 B. W. G. hard-drawn copper wire between Boston and New York. The cost of this experiment was estimated at about $70,000. It must be remembered that in those days and within the telephone interests, $70,000 was a very large sum of money, and in my opinion no man in or outside of the telephone business other than Mr. Vail would have had the courage to undertake the enterprise. I heard it referred to derisively as "Vail's baby."

At this time all the wires were overhead, consequently our copper circuit had to be strung through the network of every intervening city on poles and over housetops. When at last the lines were completed and ready for test, the industrious stringing of exchange wires in the intervening cities kept us in trouble almost constantly.

The Postal Telegraph-Cable Company was the first of the telegraph companies to adopt hard-drawn copper wire in this country, its whole system being built of it.

On August 15, 1885, the American Telephone and Telegraph Company was organized with Mr. Theodore N. Vail as president, myself as vice-president, and Mr. Edward J. Hall as secretary and general manager. The development of the system was rapid, hard-drawn copper wire was generally adopted for toll lines and very largely for exchange lines throughout the world, and its use is constantly increasing. As far back as 1896 the output for the year in this country alone was upwards of eighty million pounds.

With regard to the manufacture of hard-drawn copper wire in recent years, great improvements have been made in the process of manufacture, which cover all operations from the ingot to the finished product. When my experiments were made, it was the practice to roll a billet of copper, say of six or eight inches in width, into a long sheet and then, after being annealed, it was taken to a slitting machine and slit into square rods.

These rods were tapered by means of a hammer, in order that they might be inserted far enough through the drawing die to be grappled on the opposite side, after which they were ready to be drawn into wire. This method of starting with a square rod had disadvantages for the reason that the corners were likely to lap and fold over in the process of drawing, thereby producing flaws or bad places in the wire, these flaws becoming more and more troublesome in the smaller sizes of wire. After having been drawn through a certain number of "holes," the surface requires that it should be annealed before any further reduction in size is practicable. The new process is substantially as follows:

The copper is received from the smelting works in the form of wire bars, which are approximately fifty-four inches long, with an average diameter of about three and three-fourths inches, and weigh about 200 pounds each. These are delivered as commercial copper wire bars.

The first operation is to put the bars into what is termed a "continuous furnace," bars going in at one end of the furnace and taken out at the other. In their passage through they are heated to about 950 degrees centigrade at the rate of about two bars per minute.

Digitized by Google

The heated bars are then put through a series of grooved rolls. Each succeeding groove being smaller, the result is a reduction of the three and three-fourths inch bar to a diameter of five-sixteenths inch. These are now called rods, and are taken up on a reel in the form of a coil about thirty inches in diameter. These coils are then taken from the hot-rolling department and are cold at that time. They are then plunged into a bath of sulphuric acid and water for the purpose of removing whatever oxide has been formed in the hot-rolling operation. After about twenty minutes in this solution, the oxide is removed and the rods are then taken and thoroughly washed with clean water under a high pressure from a hose, after which they are immersed in a vat containing a lubricant of tallow and soap. The rods are now ready for the drawing process.

The rods are substantially drawn on what is termed by wire manufacturers a "continuous wire-drawing machine." That is to say, the five-sixteenths-inch rod goes in at one end of the machine, and, after passing through several dies, each one reducing the diameter and hardening the wire, it finally is drawn around a block to the finished size, say 0.104 inch.

In making this reduction, the copper is reduced in diameter from number one wire gauge to number 12 wire gauge or, in technical terms, the wire is "eleven numbers hard." This process gives the wire the greatest amount of tensile strength possible from commercial copper and yet preserves its elasticity. The cost of production is enormously reduced by the new process. Whereas, under the old process, a very skilled workman was required for each single drawing, an attendant is now able to care for several continuous drawing machines that are run at a speed unapproachable by the old method. In the smaller sizes of wire, diamond dies are employed which, in themselves, represent a very considerable investment.

Commercial copper in its soft state has a tensile strength of about 28,000 pounds per square inch, with an elongation of about thirty-six per cent., and by the cold-drawing process above described the tensile strength is increased by each number drawn, and the elongation is reduced; therefore when the copper wire is drawn eleven numbers hard it has a tensile strength of about 64,600 pounds per square inch, with an elongation of about one per cent. The wire is then taken from the wire-drawing blocks, so called, and is carefully inspected for tensile strength, elongation, torsion and conductivity. The inspected wire is then carefully packed by wrapping each coil with burlaps, so that it does not become bruised or damaged in any way by transportation.

The cost of hard-drawn copper wire fluctuates with the price of ingot copper and at present writing is quoted as sixteen cents per pound. The relative cost of copper and iron wire, say of number twelve, is three and three-fourths cents for iron and sixteen cents for copper.

The advantage of copper over iron, besides, is that it is practically indestructible, except from mechanical injury, and if it receives mechanical injury it can be made over into new wire at a cost of about two cents per pound, while iron, which is subject to rapid deterioration from rust, is worthless when taken down.

Bound Volumes of Telegraph and Telephone Age.

Bound volumes of TELEGRAPH AND TELEPHONE AGE for 1910 are for sale at the publication office, 253 Broadway, New York, at $3.50 per copy. This volume is more important and valuable than all its predecessors, and should be included in the library of every telegraph and electrical man. It contains no less than 842 pages of valuable and interesting reading matter, including educational articles, technical descriptions of telegraph, telephone, cable, wireless and other apparatus used in the transmission of intelligence.

The first issue of the year contains a complete directory of the telegraph—land, cable, wireless, railroad, etc. Among the many important articles published throughout the year may be mentioned the following: Wireless Telegraphy and Telephony, by H. S. Webb; History of Telegraph Tournaments, by Walter P. Phillips; Twenty-fifth Anniversary of the Commercial Cable Company; Rapid Cable Telegraphy; A Comparison of the Telegraph and the Telephone, by Charles Selden; New Keyboard Telegraphic Transmitter; Hughes Printing Telegraph System; Mercadier Telegraph System; Barclay Printing Telegraph System; New Western Union Quadruplex, and The Field Quadruplex. There are also many biographical sketches of prominent telegraph and telephone men.

These volumes are neatly bound in cloth, and a vast fund of information is contained within the covers.

For copies address Telegraph and Telephone Age, 253 Broadway, New York.

Busy Men.

One of our agents wishing to have someone else appointed who has more time than he had to look after our interests, gives as an excuse that "Besides my ten hours a day (on an average) in the office, I run a market garden, one greenhouse, thirty feet long and a smaller one, four large hotbeds, lawn and hedge round my place to keep in order, two agencies for insurance companies and one newspaper subscription agency besides one or two other minor things to look after, and also am a lover of the art of fly-fishing and must devote a few afternoons occasionally to the speckled beauties, so taking it all into consideration I think you'll agree with me I have quite enough to attend to without burdening myself with the duties of our professional paper."

Another operator in the West keeps himself busy by engaging in a variety of occupations. His engraved business card announces that he is an importer of French, German and Italian groceries, sole agent for a special brand of olive oil, dealer in a well-known brand of ham and bacon, proprietor of a newspaper and notary public.

Some Unexplored Fields in Electrical Engineering.*

BY DR. C. P. STEINMETZ.

In discussing the subject of the unexplored fields of electrical engineering, we must consider as belonging to the realm of the electrical engineer, all those phenomena of electricity that are of importance to man: those which are beneficial and useful, and utilized in doing the work of the world, and also those phenomena which are harmful and destructive, and therefore to be guarded against.

It is obviously impossible to touch on all the unexplored fields of electrical energy, for while electrical engineering is not in its infancy any more, nor has been for some time past, there are many more unexplored fields than there are explored fields of electrical engineering; and even in those fields which have been most carefully investigated we find still many unknown regions. A lot of work has been done along many lines since the early days of electrical engineering and a lot of different fields have been uncovered; but there are larger fields still unexplored and there are regions that are still unknown.

To illustrate—there is no simpler and apparently better known phenomenon than the resistance of a conductor. A conductor has a definite resistance which varies with the temperature, etc. With the alternating current the resistance apparently increases in large conductors, because the current flowing in the conductor is not uniform throughout the entire section, but, by the screening effect of the magnetic field inside the conductor, the current density inside of the conductor is less than it is on the outside. We can calculate the phenomena of the lack of uniformity of the current density in the conductor for the case where the current density is not yet very un-uniform, as if in the center of the conductor the current density is only from 5 to 10 per cent. lower than on its periphery. We get an approximation which is satisfactory for all purposes of electrical engineering, and shows us how large a conductor we can use without serious waste of conductor material. Then there is the other extreme, where the current density in the middle of the conductor is practically zero, and the current is limited to a thin shell on the outer surface as in the rail return of the single-phase railway, or in ordinary conductors at very high frequencies, as with lightning discharges. This case we can also calculate, determine the current distribution in the conductor, the apparent penetration and the effective resistance of the conductor, with an approximation as close as our knowledge of the constants of the material, the conductivity and permeability permits. But when you come to the intermediate and probably most interesting case, where there is current even in the center of the conductor, but a material difference in the current density between the outside and the center of the conductor, we find as solution an infinite series, which in this case converges so slowly as to be practically useless, and this case thus is still practically unexplored.

In some fields of electrical engineering or of electrical science we might almost say that we know less now than we knew, or rather believed we knew, a quarter of a century ago. There are things which had been investigated a quarter of a century ago and which were explained in a satisfactory manner to our limited knowledge in the early days, but this explanation does not seem satisfactory now with our greater knowledge.

A curious example we might cite from the textbooks on natural history, for instance. There are supposed to be some fishes which are capable of giving electric shocks. There are some species of gymnotus in the South American mud creeks capable of imparting electric shocks, which have been described a number of times, fishes which have an organ which generates electricity. It has been described as being constituted like a Volta-pile, of a number of successive cells. That theory was quite acceptable twenty-five years ago, but is not satisfactory now. To give a severe shock would require about 500 to 1,000 volts, and it is not intelligible how such voltage could be generated in the conducting animal tissue without being short circuited. Furthermore, the fish is immersed in water, which is a fair conductor, especially sea water, and 500 volts or more would produce hundreds of amperes in the surrounding water, representing hundreds of kilowatts, and it is not intelligible how such a large power could be generated even momentarily. Thus here we have a mystery, because, after all, the descriptions have been so concise that it is difficult to doubt that there are fishes which can give electric shocks. Just why that phenomena has not been investigated by electrical engineers, we do not know, especially when considering that one of the electric fishes, raja torpedo, lives in the Mediterranean and is frequently caught on the Italian shores, as claimed, thus is within easy reach of engineers.

But we do not need to go so far from home; right at hand we have some of the most important uninvestigated phenomena of electricity. The thunderstorm, the lightning, and so forth. In the early days lightning was explained as the discharge of the clouds. The clouds are positively charged, and the ground is negatively charged, and the spark jumps from the cloud to the ground. Speculations were made as to how the clouds became charged, and as then the only method of producing electricity was by friction, it was said it might be the friction of the vapor through the air, or the rain drops through the air, or some other form of friction. That explanation used to appear satisfactory, but with our present knowledge of dielectric phenomena, it is not satisfactory any more.

It was thought that lightning was the discharge from the cloud to the ground. That means that the electric field between the cloud and the ground must

*Abstract of paper presented at the joint meeting of the Electrical Section of the Franklin Institute, Philadelphia, and the Philadelphia section of the American Institute of Electrical Engineers, and printed in the June number of the Journal of the Franklin Institute.

Digitized by Google

be beyond the breakdown strength of air. In a uniform field the breakdown strength of air is about 75,000 volts per inch, or nearly a million volts per foot. Even if the cloud is only 1,000 feet above ground, this would require a thousand million volts. If there were an electrostatic field between the cloud and the ground of a thousand million volts extending over the whole area of the thunder cloud, this would represent such an immense amount of electric energy that it is inconceivable how any reasonable source of energy can produce it; how it can exist without having a destructive effect far beyond anything known of lightning. Furthermore, a uniform field cannot well exist between clouds and ground, on account of the unevenness of the ground surface.

We cannot consider the lightning discharge as a simple electric rupture in the same way that an overloaded beam may break mechanically, but as an equalization of internal stresses, about as a piece of hot glass that is rapidly chilled, and thereby full of internal compression and tension strains may suddenly break all over by the internal stresses. So with our present knowledge we must consider as the most probable explanation—although not certain by any means—that the lightning discharge is the phenomenon of the equalization of internal electric stresses in the cloud, and is analogous to the splintering or breaking of an unevenly stressed brittle material, like glass.

Lightning discharges are the result of the voltage inequalities produced in the clouds by the unequal rate of conglomeration of rain particles due to the unequal cloud density.

In agreement with this is that heavy lightning strokes are usually followed by a heavy downpour of rain; in reality they are preceded and caused by it, but it takes time for the rain drops to come down.

We now find that in the study of electrostatics the conceptions of the work of former days is untenable, from our present point of view; we cannot conceive of the dielectric phenomena as a charge on the conductor surface; we know there is not an electric charge on the conductor, the dielectric energy resides not on the conductor surface, but is in the space around the conductor in a dielectric field, and the so-called "charge" is nothing but the termination at the conductor surface of the electrostatic field in space. It is the electrostatic or dielectric field which we must consider as representing the phenomena of electrostatics, in the same way as Faraday has shown us with the magnetic field.

The old conception of the electrostatic charge on the conductor has been the cause of the far greater difficulty which we find in dealing with even simple phenomena of electrostatics, compared with the simplicity with which even apparently complex phenomena are treated by the conception of the lines of magnetic force.

We must then abandon the conception of the theory of electrostatics of the early days—which still largely is used in theoretical text-books—as incorrect and useless. Capacity then is not the capability of the conductor to store electric quantity, but is the ratio of the number of lines of dielectric force, to the electromotive force which produces them, just as permeance is the ratio of the number of lines of magnetic force, to the magnetomotive force which produces them, the "charging current" is no more a current charging the conductor with electricity than the "inductance voltage" is a voltage charging the conductor with magnetism; the former, as "capacity current" supplies the energy stored in the dielectric field, just as the inductance voltage supplies the energy stored in the magnetic field, and dielectric and magnetic phenomena are very largely analogous and treated in the same manner, and with the same simplicity.

Replying to questions during the discussion Dr. Steinmetz said: While we still speak of electricity, or of magnetism, these terms have really ceased to have a definite meaning of some concrete thing or phenomenon, but rather mean an entire class of energy phenomena. With our increasing knowledge, instead of speaking broadly—and vaguely—of electricity, we discuss electric power, electric energy, electric current, voltage, quantity, etc., so that it may be said that there is no such thing as electricity, but there is electric energy, electric power, etc., and the term electricity is applied largely to an entire class of phenomena. We may ask, "What is electric energy?" and then would answer that it is a form of energy which can be transmitted through a conductor, around which conditions of magnetic and dielectric stress are produced.

Some speculative physicists have developed a conception of two forms of electric quantity, negative and positive. Others have denied the existence of positive and recognize only an excess or a deficiency of negative electric quantity. However, in reality, there is no absolute negative or positive, but it is entirely relative. That is, a point which is positive against another point may be negative against a third point. For instance, the negative terminal of the mercury arc rectifier is the positive terminal of the rectified circuit fed by it.

You might define the electrostatic or dielectric field as a condition of stress in space, which exerts mechanical forces on light bodies, and which is polarized, that is, the forces may be in one, or in the opposite direction, positive or negative.

The lightning rod is a great protection, and I would not like to be in an exposed place without such protection. But you must not expect that one rod on one end of the building will completely protect the other end a hundred or more feet away. There must be sufficient rods to extend their protective zone over the entire area; the apex of the roof, and other projecting edges must be protected by connecting wires, etc. That is, like any other apparatus, the lightning rod protection must be installed intelligently and properly to be effective. But the general principle is correct, only it must be rationally applied.

Portable Storage Batteries as Applied to Automatic Signal on the Harriman Lines.*

The application of portable storage batteries to signal circuits on the Harriman lines began in the year 1890 on the Western Division of the Southern Pacific, under the direction of Mr. W. W. Slater, then master of signals of that company. At the time there were no motor-operated signals on the Southern Pacific lines and the use of portable storage batteries was confined to operating highway crossing bells and indicator and locking circuits at hydro-pneumatic interlocking plants. The type of battery then in use was crude, heavy and of generous dimensions for its capacity. It was found that a considerable saving was effected through the use of these portable storage cells as compared with the cost of operating the circuits with primary and gravity cells and with a view of extending the use of storage cells to several installations of single track electric automatic block signals that were contemplated, tests were carried on for several years with various types of portable storage batteries on the market. The results of these tests were so satisfactory that in 1899 and 1901 when these several installations of automatic signals were completed, the experimental stage had been passed and portable storage cells were decided on as being the least expensive and most satisfactory source of energy for operating the motor circuits.

Gravity batteries were used for the line and track circuits, although later the gravity line batteries were dispensed with and the storage battery served the double purpose of operating both line and motor circuits. At the foremen's headquarters of each installation a charging outfit, consisting of a 2 H.P. gasoline engine, belt connected to a 1 k. w. generator was installed; the foreman attending to the work of charging and inspecting the batteries, and distributing them to the nearest stations on local passenger trains where they were taken to the battery locations by the maintainer on a velocipede or motor car; the discharged batteries being returned to the charging plant in the same manner. From this small beginning the operating officers of the associated lines, comprising the Harriman System, recognized the advantages of automatic signaling as a means of facilitating and safeguarding traffic, with the result that each year additional mileage of automatic signals was authorized, the amount of such mileage usually being the maximum that could be installed by the signal departments of the various lines during the year. With the close of 1910 the entire main lines of the Union Pacific and Southern Pacific from Omaha, Neb., to Oakland, Cal., a distance of 1,779 miles, is protected for the entire distance with automatic block signals, except about 100 miles over the Sierra Nevada mountains, where the electric train staff is in service. Also the main lines of the Oregon Short Line and the Oregon-Washington Railroad and Navigation Company between Granger, Wyo., and Portland, Ore., are protected in a like manner, for the entire distance of 941 miles.

The main lines of the Southern Pacific from Portland, Ore., to El Paso, Tex., and the Sunset Lines from El Paso to New Orleans, a total of 3,226 miles, are protected with automatic signals for a distance of 1,938 miles, or 60% of the entire distance and it is calculated that the remaining 1,288 miles will be completely signaled within two years. The total mileage of road protected by automatic signals on the entire system, on December 31, 1910, was 4,719 miles of single track, and 703 miles of double track, or a total of 6,125 miles of track so protected. On this mileage there are 12,050 automatic signal blades, practically all of which are operated by portable storage battery. There are in all 9,026 battery locations with a total of 48,516 type SS-7 cells in service, of which 12,412 cells, or 25%, are extra cells used for changing.

The method of transportation to and from the charging plants vary with local conditions. On portions of the line where local passenger service is available, the batteries are loaded into the baggage car and distributed at each station by the batteryman, who accompanies the batteries. From the stations they are taken to the various battery locations by the maintainer on a velocipede or motor car, the discharged batteries being returned in the same manner to the station, where they are picked up by the batteryman and brought back to the charging plant on the return train in the evening. On other sections of the line the batteries are loaded into a specially arranged battery car and handled on local freight trains, stops being made at each battery location, where the batteries are changed by the batteryman and the maintainer on that district. The car containing the discharged batteries is sent back to the charging plant on the first freight train. Another arrangement consists of a charging plant built in a box car, which car is moved on the daily way freight and is set out at each alternate station; the batteries being changed out in each direction from the station by the maintainer. During the three years that this portable arrangement has been in service, it has given the best of results, handling on one district 832 cells monthly on a territory of 150 miles of single track signals. An important advantage in this method is that on the 150-mile district referred to only eighty extra cells are required for changing out purposes, this being only 10% of the total number of cells in service in the district.

On the Harriman Lines there are fifty-two charging plants, each of which (except the portable plants) is located at the headquarters of the assistant supervisor, where a shop building is provided, and part of this shop building is used to house the charging machinery, hence no special building is necessary. The average territory covered by each plant is 104 miles. Wherever current can be obtained from local power companies, a mercury arc rectifier or motor generator set is installed and at other locations where electric power is not available, a gasoline engine and generator charging outfit is used. All cells are returned to the plant monthly and are thoroughly inspected and cleaned before being put on the charging circuit.

*Abstract from the Journal of the Railway Signal Association.

In the case of stationary batteries it is the usual practice to give an overcharge several times a month, the overcharge having the effect of driving the sulphate out of the plates and keeping them in a healthy condition. Portable cells which are chared once a month only, are subject to considerable sulphating and therefore require a long charge to bring them up to capacity. It is the practice to continue the charge for two or three hours after the voltage and specific gravity has ceased to rise. The uniform gassing of all cells on charge is a good indication of their condition and the failure of any cell to gas is investigated before the charge is continued. During the charge, voltage and specific gravity readings are taken and recorded in the book and any cells not coming up to the proper voltage and gravity are closely watched and given special treatment if necessary. Maintainers are required to make weekly inspection of all cells in service, examining them for loose connections, taking voltage readings and replacing any evaporation of electrolyte that may occur during the time the cells are in service. In replacing the evaporation, only water whose purity has been previously passed on is used. In localities where pure water is not obtainable, distilled water is provided.

The Day Letter.

President Theo. N. Vail, of the Western Union Telegraph Company, says regarding the introduction of the new day letter service: "The defects of the telegraph system of to-day are collection and delivery; old fashioned, primitive, slow, unreliable and expensive. It costs more to collect or deliver a message than it does to transmit it. It is like riding from Boston to New York over 220 miles and then paying 20 per cent. more to get yourself and your gripsack down to your hotel.

"Another defect is that out of 25,000 Western Union offices less than 5,000 have enough gross receipts to pay the operating expenses of an exclusive office. Consequently at the other 20,000 offices the staff must be a joint staff; and generally it is a railroad employe, drug clerk, or some similar employe of another business who runs the telegraph business. His first allegiance is to his employer and to his employer's business. The telegraph company is not his employer; consequently the telegraph business is secondary, subordinate. It is the business of this class of offices that very largely makes the reputation of the service. The public cannot discriminate; it does not know anyone but the telegraph company. A company not having this handicap should give an almost faultless service.

"What we are trying to do is to eliminate the imperfections in collection and delivery and also by joint occupancy and joint use with telephone companies get all offices in the custody and charge of employes who have only one interest to serve. Until this is done general improvement cannot be made in the service.

"All telegraph and cable service has been developed along the lines of expedition. But theoretically there can be no greater expedition than under the present methods. An expedited service means surplus facilities to meet the maximum demand and means despatch immediately on receipt. To handle an expedited service during the four or five rush hours of the day means having a plant which must stand idle up to 60 per cent. of its capacity during most of the remaining hours of the day.

"It is our intention to try out first and see if we cannot, without raising present rates, which are very cheap considering service performed, make this regular business the expedited business and ultimately give deferred business at cheaper rates, rather than expedited business at higher rates. We may fail in the attempt.

"It is interesting to know that theoretically Western Union stands to lose $1,250,000 in annual revenue through the day letter. This means that if all messages now sent with enough extra words to make the rate above the day letter rate should be sent as day letters the loss of revenue will be $1,250,000. We must do that amount of day letter business to break even for this innovation.

"I have faith enough in the business and social uses to which the day letter can be put to think that when its advantages are understood it will be exceedingly popular.

"If it succeeds and we have not broken the backbone of the company's revenue, then a deferred short message at some more favorable rate may be considered. But the primary object is to leave the present expedited (i. e., regular business) at present rates with as fast transmission as would be possible at any price."—*Cleveland Telephone News.*

New Books.

"Telegraphy," by T. E. Herbert, has been revised and brought up to date. This volume gives a detailed exposition of the telegraph system of the British Post Office, and while the apparatus shown is of English design, there is much other matter of value to the American telegraph engineer. The subject of telegraphy is very completely covered in the twenty-two chapters of the book, and the descriptive matter is so clearly written that the student should have no difficulty in grasping and absorbing the ideas and information given.

An idea of the scope of the book may be gained from some of the chapter headings, viz.: Fundamental principles; primary cells; calculations in connection with circuits and conductors; galvanometers, resistance coils and shunts; battery testing; single current systems and relays; duplex; quadruplex; repeaters; different systems of telegraphy; construction of aerial lines; construction of underground lines, etc. The appendix includes a complete description of the Murray automatic system. The book has 912 pages and a very complete index to its contents. Price $3.00. Address J. B. Taltavall, publisher, 253 Broadway, New York.

Any book on electrical subjects can be obtained at the office of Telegraph and Telephone Age, 253 Broadway, New York.

Co-Operation Between Railroad People and Commercial Companies.*

BY W. P. CLINE,
SUPERINTENDENT TELEGRAPH, ATLANTIC COAST LINE,
WILMINGTON, N. C.

Every superintendent of telegraph believes, and with reason, that upon the efficiency of the telegraph depends, in a large measure, the success of all other departments of a railroad. He may not find many enthusiastic endorsers of this flattering view until, perchance, it fails, somewhere, in the customary performances of its functions; then, the very complaints that pour in upon him, of what it has failed to do, attest its value. His ambition is, therefore, to maintain a service upon which all users may confidently rely.

It is the purpose of this paper to refer to a condition that militates disastrously against his achievement of this object. That condition is the lack of cordial co-operation between local officials and employes of railroads and those of contracting commercial telegraph companies. Wherever such a state of affairs exists, the result must be confusion; and although it may be confined principally to one road, it reflects unfavorably upon others. The subject is believed to be of sufficient general interest to warrant a brief discussion by this body.

In a certain commercial office the wire chief was found one day, figuratively, tearing his hair. He was in a most unhappy frame of mind. The cause of his perturbation was a peppery communication from his superintendent, forwarding an equally spicy complaint of a railroad official, in a distant city, regarding the condition of his railroad wires which were said to be in trouble. The complaint stated that they were always in trouble and that no attention to them could ever be secured. The contract called for wires, and wires must be furnished forthwith.

This wire chief is, indeed, very competent, very vigilant; and, although this statement may be questioned, has every disposition to give the railroads a square deal; but he proved by his log that the wires had never been in trouble; that if they had been, they had come clear before the lineman got there. Anyway, nobody had ever called his attention to them.

This story is not altogether a fancy. The situation as described may not be appreciated by those of us who, having the requisite organization, construct and maintain our own telegraph lines and are, therefore, able to point with pride to a perfect equipment and a perfect service; but to those who must look to a contracting commercial company for the maintenance of railroad wires, it is very real and we know that there is often at least a shadow of justification of such a complaint from a railroad source and also a shadow of truth in the explanation attributed to the wire chief.

As a matter of right, a railroad company expects the wires, batteries and apparatus assigned to its use to be maintained at all times in such condition as to be efficient for railroad service.

As a matter of fact, it is too often true that a very low degree of efficiency is considered good enough for a railroad circuit.

It sometimes appears that the commercial company's wire chiefs are satisfied so long as a railroad wire "works," although it may be in such condition that its use in commercial service would be considered impracticable and if some of us were to find out that our railroad wires were being tested, even occasionally, for insulation and conductivity, or that a lineman or other inspector had visited our railroad offices for the purpose of preventing trouble by discovering and remedying defects before their presence could be made known in the usual way—well, we would be mildly surprised, to say the least.

If this be true, it may be asked, "why talk about co-operation when, apparently, the commercial company is lax in the performance of its contract duty?"

The answer is that without a certain form of assistance from the railroad people, the performance of the commercial company's duty is made so difficult that its human representative, the wire chief, becomes discouraged and, therefore, not unnaturally, indifferent if not actually antagonistic to the railroad's interests.

In a typical case like the one described, it was the custom to rely wholly upon the commercial company to investigate every wire trouble. It was "up to them" because the contract said so. The inevitable result was inefficient telegraph service, with its train of annoyances.

Conditions improved when the custom was changed from absolute reliance upon to at least a partial co-operation with the commercial company. Among the more important details that brought about the improvement was a change in the attitude of railroad officials towards office troubles. It is safe to say that the major proportion of interruptions to railroad telegraph circuits is due to loose connections, open keys or grounds in offices. These are avoidable. Chief dispatchers were directed not to call upon the commercial company to investigate open and grounded wires until they had satisfied themselves that the trouble was not in some office. They were directed also to see that a "wire" signal when used on a railroad wire by the commercial company's wire chief was duly respected and was not to be the signal for a command from a dispatcher or operator to "get out," with, perhaps, a few choice epithets thrown in by way of emphasis.

Roadmasters, also, were reminded that the telegraph line is a very important part of the railroad's equipment and were directed to have their forces give it reasonable attention and make reports of defects that they might be unable to repair.

Pursuance of the policy thus briefly outlined has shown most gratifying results. We believe, however, that our success in having these standards applied and, consequently the quality of our telegraph service, will depend very largely upon the extent to which we shall be able to bring our own people to realize the value of and the necessity for free co-operation with our commercial friends.

*Paper read at the Convention of the Association of Railway Telegraph Superintendents, Boston, Mass., June 26.

There Were No Blue Ribbons

Some of our friends were kind enough to say that our display would have taken a high prize if there had been awards for the exhibits at the Boston Convention.

To those who called on us there we express our appreciation of their interest. To the possibly larger number who could not attend but whom we are also in a position to serve, we extend greetings.

Let our engineers confer with you over your most difficult problems. Send for any of our literature; it is not merely catalogue matter, but "reason-why" writing. Call at our offices if you can.

As the only manufacturing concern devoting its energies exclusively to electrical apparatus for railway service, we are better equipped to meet adequately railway needs than are concerns with more general and more diversified product.

Pocket Relay

Bunnell Pattern. Has all the practical qualities of a full size Sounding Relay and is a very compact and handsome instrument.

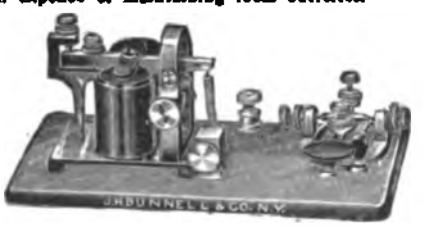
Furnished with nicely finished carrying case 5¼ in. long, 2¾ in. deep, 2½ in. wide.

List No.		Each.
581	Wound to 150 ohms, with Case	$12.00
6226	Wound to 250 ohms, with Case	12.50

NEW
Main Line Sounding Relay

"MCM" MODEL.

New and important improvements, instantaneous adjustment of both armature spring and distance from magnet cores, both adjustment nuts conveniently located in front. The arrow on the upper adjusting nut indicates the relative distance between armature and magnet cores, the string arrangement used in the old-style tension springs is entirely dispensed with, and a wide and rapid range of spring adjustment obtained by a cam lever operated by the lower adjusting nut. The "MCM" model retains all the good points of our original type of instrument, and is intended for use on main lines in place of the ordinary relay, and dispensing entirely with the local sounder, thus saving the continual expense of maintaining local batteries.



No. 559

559	150 Ohms, with key on base	$6.00
560	150 Ohms, without key	4.90
561	Mahogany case for wrecking sets	2.00
562	Leather case	6.00
563	250 Ohms, with key on base	6.30
564	250 Ohms, without key	5.20
565	20 to 100 Ohms, with key on base	5.70
566	20 to 100 Ohms, without key	4.60

Nos. 563 to 566 are for all circuits from 1 to 100 miles in length, when, with ordinary Main Battery power suitable for such lines, they are equal to the best local sounders.

10 LINE PLAIN TYPE.

The Neatest, Quickest, Best and Slickest Switch

Railway Efficiency.*

BY RALPH W. POPE, NEW YORK.

The commercial activity of a country is based on production and distribution. The main factor in distribution is transportation, and this is the service for which the railways are mainly responsible. To carry on this work with safety, convenience and celerity, the telegraph department has become practically indispensable. If, therefore, the inefficiency of the railway management is represented by an expenditure of $300,000,000 annually the telegraph departments of the various companies would naturally be called upon to assume their share in the general increase in efficiency.

In considering the question of efficiency the peculiar character of the railway problem confronts us. Scientific management has been so prominently exploited that it has been hailed as the forerunner of universal prosperity. The examples cited usually indicate that by means of scientific methods a tremendous gain has been possible in the output of each human unit engaged in coal shoveling, pig iron shifting and bricklaying. It is obvious that similar gains in efficiency are possible and have been made in the past in various branches of manufacturing.

The increase of output has been the constant study of manufacturers, and in many cases at the sacrifice of quality and durability. The retail price of many manufactured articles is so small that we can scarcely realize the possibility of its covering the actual cost of labor and material, without reckoning the usual margin of profit. At any time, and in any part of the country, articles manufactured in large quantities may be purchased even at retail at prices which indicate that little can be expected from increased efficiency.

Using the language of Mr. Julius Kruttschnitt, Director of Maintenance and Operation, Union Pacific System and Southern Pacific Company, in a lecture delivered at Harvard University, April 26: "A railway is a machine designed to manufacture freight and passenger transportation; it makes ton miles and passenger miles."

Viewed as such a machine it is obviously inefficient, because it cannot be operated to its full capacity at all times, for the simple reason that equipment and labor must remain idle at certain hours on different lines which in the aggregate appears as a stupendous yet apparently unavoidable waste. This is more apparent on single track than double track lines, and it has been the mission of the telegraph to facilitate train movements, as far as may be compatible with safety. The telegraph is an important part of the "machine" but is not considered a revenue producer like the freight and passenger service. It must carry its own burden of cost of operating and maintenance and will no doubt be expected to share in any general increase of efficiency. Every branch of the railway service has for years been represented in various technical associations, twenty-five of which are national in character. There are more than this number of local clubs, and all of these organizations through their meetings, conventions and committees, are continually engaged in the promotion of efficiency in their various departments. This work is in the hands of experts in their respective lines, and is regularly and systematically supplemented by the technical journals. Not only is every advance step promptly and accurately published, but even the minutest details of improved methods are spread broadcast through the collections of "shop kinks" for the benefit of whoever is interested in railway work. All of this makes for efficiency and possesses the important feature of being exempt from overhead charges, and revolutionary innovations, which may be irritating to managers as well as employes.

This question of efficiency should be thoroughly studied in connection with the introduction of the telephone, into the domain of the telegraph. The superiority of the telephone for certain purposes is, of course, admitted by all. In a certain sense a great railway system is an active community in itself. Its organization embraces the entire industrial field. It operates factories and shops, cultivates gardens and forests, it runs hotels and steamships, it has its legal and medical departments, and is generally believed to at least be interested in municipal, state and national affairs. If the telegraph has a field of its own in our national life, surely it must also be a necessity in railway organization.

In the exchange of ideas bearing upon the welfare of the telegraph, do not for a moment quail at the suggestion of "higher-efficiency." This has been your purpose, and it was for this object that the Association of Railway Telegraph Superintendents was organized.

*Paper read before the Convention of the Association of Railway Telegraph Superintendents, Boston, Mass., June 26-30.

The Eiffel Tower Wireless Station.

At the recent meeting of the Société Française de Physique in Paris, Commandant Ferrié described the wireless telegraph station of the Eiffel Tower. This station is particularly remarkable, says Mr. S. H. Russenberger in *Electrical World*, because the antenna is supported by a tower 300 meters in height, which permits the receipt of communications from a great distance, even from America. Thus the visitors were able to read in the dispatch book messages that a gentleman signing himself Charles and another gentleman signing himself Adolphe sent to Mlle. Polaire at the moment when that charming actress started on her return to France. These two gentlemen will doubtless be less enthusiastic over the great modern discovery when they learn that their declarations were readable more than 5,000 miles beyond the beloved object to whom they were sent. The writer placed his ear to the telephone receiver, but did not have the good fortune to hear a communication of this importance. He simply received the time of day from the station at Gibraltar, 900 miles from Paris.

CONVENTION OF ASSOCIATION OF RAILWAY TELEGRAPH SUPERINTENDENTS.

The annual convention of the Association of Railway Telegraph Superintendents was held at the Hotel Brunswick, Boston, Mass., June 26-30, and was largely attended.

In the absence of President I. T. Dyer, of Los Angeles, Cal., First Vice-President J. B. Sheldon, of Omaha, Neb., presided.

The first session was called to order at 2.15 p. m., and in opening the proceedings the acting president referred feelingly to the absence of President Dyer, and then spoke of a distinguished guest present, Mrs. George S. Minot, a niece of the late Charles Minot, general superintendent of the Erie Railroad, who sent the first telegraphic train order, which event is to be commemorated by the erection at Turner, N. Y., of a monument.

Mr. E. P. Griffith, chairman of the Turner Monument Fund in a few well chosen remarks introduced Mrs. Minot, who thanked the members for the distinction paid her. Mrs. Minot resides in Brookline, Mass.

Mr. A. N. Bullens, assistant superintendent of the contract and revenue department of the New England Telephone and Telegraph Company, Boston, on behalf of that company and the American Telephone and Telegraph Company, extended an invitation to the members to the free use of the local service at any time during the convention and of the toll service between the hours of 4 p. m. and 9 a. m. The two telegraph companies also extended like courtesies.

After the approval of the minutes of the Los Angeles convention of last year, Secretary Drew read a letter from President Dyer expressing his regrets at his inability to be present on account of ill health. Mr. Dyer referred to the excellent work of the Association during the year, and mentioned especially the labors of the Committee on High Tension Wire Crossings. Regarding the time of holding meetings he suggested the propriety of setting a fixed date for the conventions, and thus avoid the annoyance of changes of dates as has been done on one or two occasions lately. He praised the work of the officers and the various committees.

After the reading of telegrams from absent members the following new members, active and associates, were elected by ballot:

Active—H. A. Shepard, assistant superintendent telegraph, New York, New Haven & Hartford R. R., New Haven, Conn.; H. A. Vaughan, assistant superintendent telegraph, Chicago, Burlington & Quincy, Lincoln, Neb.; G. L. Candler, superintendent transportation, Central of Georgia, Savannah, Ga.; G. O. Perkins, superintendent telegraph, Chicago, Great Western, Chicago; F. E. Camp, inspector of telegraphs, Canadian Pacific Ry., Revelstoke, B. C.; E. A. Speer, inspector of construction, Canadian Pacific Railway, Toronto, Ont.; E. M. Payne, inspector of telegraph, Canadian Pacific Railway, Winnipeg, Man.; J. E. Golden, superintendent telegraph, Tidewater Pipe Line Company, Bradford, Pa.; C. W. Stockdale, general foreman, Illinois Central, Chicago, Ill.; C. W. Bradley, acting superintendent telegraph, Chesapeake & Ohio, Richmond, Va.; A. C. O'Brien, telephone inspector, Boston & Maine, Boston, Mass.

Associates—G. K. Heyer, Western Electric Company, New York; C. T. Wilkinson, General Electric Company, Schenectady, N. Y.; D. W. Dean, special agent, American Telephone & Telegraph Company, St. Louis, Mo.; A. F. Everman, Bell Telephone Company, St. Louis, Mo.; W. L. Cook, sales-engineer, United States Electric Company, Chicago; J. H. Finley, Western Electric Company, Chicago; E. L. Howk, Western Electric Company, Chicago; Vernon Durbin, Holtzer-Cabot Company, Brookline, Mass., W. O. Nevil, special agent Missouri & Kansas Telephone Company, Kansas City, Mo.; Henry Homer, special agent American Telephone & Telegraph Company, Philadelphia, Pa.; E. Whitmore, Manhattan Electric Supply Company, New York; A. D. Smith, Northern Electric Manufacturing Company, Montreal, Que.; J. F. O'Donnell, manager Western Union Telegraph Company, Joplin, Mo.; H. G. Thompson, manager Edison Storage Battery Company, Orange, N. J.; L. H. Merrill, special agent Northwest Telegraph Exchange, Minneapolis, Minn.; G. Brown, Western Electric Company, New York; E. E. Hudson, manager of sales, Edison Storage Battery Company, Orange, N. J.; A. G. Francis, railroad agent, Chicago Telephone Company, Chicago, Ill.; E. M. Fisher, commercial superintendent, Cumberland Telephone & Telegraph Company, Nashville, Tenn.; R. B. Crane, general sales agent, Rock Island Battery Company, Cincinnati, Ohio; A. D. Walters, special agent, New York Telephone Company, New York; E. V. Adams, railroad sales agent, Western Electric Company, Chicago; H. B. Fenn, special agent for Railroads, New York Telephone Company, Newark, N. J.; L. G. Martin, Okonite Company, New York, N. Y.

G. A. CELLAR,
of Pittsburg, President Association of Railway Telegraph Superintendents.

Secretary Drew then read his report, which showed the Association to be in better financial condition than ever before in its history, having a sub-

Digitized by Google

stantial balance in bank. At the time his report was made up there were 102 active members in good standing and 67 associates, making a total of 169 members in good standing, notwithstanding the increase in dues.

The report of the auditing committee was then read by Chairman A. B. Taylor. This report and that of the Secretary-Treasurer were adopted.

The report of the executive committee was received. Some changes in the constitution were recommended.

Hon. J. F. Fitzgerald, Mayor of Boston, was then introduced and spoke in complimentary terms of the association, and extended a hearty welcome to the city. He referred to the historical, educational and literary features of the city and the independence breathed in its atmosphere.

Speaking of the telephone and the telegraph, he stated that he had a great admiration for Mr. Theo. N. Vail, president of the American Telephone and Telegraph Company and of the Western Union Telegraph Company. He (Mr. Fitzgerald) and Mr. Vail were very good friends and Mr. Vail had a master mind. He compared telegraphy and telephony abroad with those services in this country and told of an instance where, in Paris, it took him four hours to get a telephone connection three blocks away in the middle of the night. He also referred to the necessity of having to speak several languages in order to get a long distance telephone connection in Europe, and paid a high compliment to the service in this country. Mayor Fitzgerald closed his remarks with a song which he said he sang in the last campaign and has been singing ever since. His address had many humorous touches and was enthusiastically received.

Mr. G. A. Cellar was called upon to reply to Mayor Fitzgerald, which he did in a humorous yet dignified manner.

After the presentation of the report of the topics committee, of which Mr. W. C. Walstrum is chairman, Mr. W. J. Camp read a paper entitled "Some Hints." A lengthy discussion followed the reading of the paper and was participated in by Messrs. Griffith, Johnson, Ditch, Caskey, Kissinger, Cellar and A. B. Taylor. Mr. Johnson asked Mr. Camp if he had found any trouble with porcelain insulators on account of smoke and if he had experienced any difficulty from cobwebs in insulators. On certain parts of his line, he said, cobwebs were very troublesome. Mr. Camp stated that smoke deposits upon insulators lower the insulation of the line very much but that they could be washed off. The same trouble applied to glass insulators as well. He had no trouble from cobwebs on his lines on account of the dryness of the climate, except in the maritime provinces, where the atmosphere is moist.

Mr. Cellar stated that a more rigid inspection was necessary for porcelain insulators than for glass.

On the subject of transposition Mr. A. B. Taylor found that transposition of telephone lines every half mile on his road answered every purpose. Mr. Camp referred to the transposition designed by Mr. R. E. Chetwood, engineer of construction of the Western Union Telegraph Company, New York.

Mr. J. C. Johnson stated that transposing on his road, the Pennsylvania, was laid out scientifically, and took into account every factor of situation, influence, etc. All his wires were paired for telegraph as well as for telephone purposes, and the transposition was made from the telephone standpoint. Referring to the subject of lightning protection he stated that his company used all the lightning protection it could.

Mr. Sheldon said that Brach lightning arresters had been used on his lines for several years and were giving very satisfactory service. Each office was equipped with an arrester.

The meeting then at 5:15 p. m. adjourned until 10 a. m. Tuesday.

TUESDAY'S SESSION.

The meeting was called to order at 10:15 a. m. by Acting President Sheldon who introduced Mr. Belvidere Brooks, general manager, Mr. A. G. Saylor, general superintendent, and Mr. R. E. Chetwood, engineer of construction, Western Union Telegraph Company, New York. Each of these gentlemen made a few remarks expressing their pleasure at being present and hoped that the convention would be a profitable one. Mr. Saylor stated that no organization in the world had produced so many intelligent and able men as the telegraph.

Mr. W. P. Cline then read a paper on "Co-operation Between Railroad People and Commercial Companies." (The paper is published on another page of this issue.) The discussion, which was participated in by Messrs. Selden, Griffith, Camp and Chetwood, brought out much valuable information relating to telegraph line construction and maintenance.

Mr. Saylor emphasized the importance of good wire service and related some of his early experiences with railroad lines. He commended the present system of specialized maintenance as practiced in the divisional organization.

Mr. Griffith spoke of the rapidity with which telegraph troubles are cleared in modern railroad practice.

Mr. Chetwood stated that the present 15-ampere fuse with a carbon block will eventually give way at the outer end of cables to a fuse protection, the lightning protection all being outside the office. An arrangement of switching is now being planned by which through wires running through offices closed for the night can be switched out of the office.

Digitized by Google

Mr. Camp referred to the difficulty of simultaneous operation of railroad and commercial service on his lines.

Mr. Chetwood stated that the double-petticoat porcelain insulator is about four times as good as glass, but final conclusions are yet to be established. Signs of aging of porcelain are apparent. A new type of double-petticoat glass insulator has been designed and tests indicate about 75 per cent. better insulation than former types, besides being less fragile than the older types. At this time a porcelain insulator does not appear generally justified for telegraph lines except for exceptionally long haul service. A porcelain insulator to be of any value must be absolutely non-absorbent.

Mr. Saylor cited the difficulties of operating iron wires in rainy weather regardless of the type of insulator used.

Messrs. Selden, Chetwood and Camp spoke of the relative advantages of iron and wooden insulator pins.

Mr. J. L. McQuarrie of New York then read a paper on "Some Observations on Telephone Transmission."

The afternoon session opened with a discussion of Mr. McQuarrie's paper. Mr. Wm. Maver, Jr., characterized the paper as an historical and practical discussion of the subject. Messrs, C. Selden and J. J. Ghegan also spoke briefly.

Mr. G. A. Cellar then presented the report of the High Tension Wire Crossing Committee. The report was received and approved and the committee continued. The Western Union and Postal Telegraph-Cable Telegraph Companies and the American Telephone and Telegraph Company are to be invited to co-operate in future work in this direction.

Mr. W. W. Ryder read Mr. R. W. Pope's paper on "Railway Efficiency." There being no discussion, the report of the Committee on Form for Delivery of Messages to Trains, Etc., was read by Mr. E. P. Griffith, chairman. No uniform form has yet been agreed upon, but having ascertained the sentiment of the telegraph companies on the subject, a satisfactory conclusion of the committee's work is assured.

The Turner Monument Fund was the next subject taken up. Mr. E. P. Griffith, chairman of the Fund, gave a brief history of the project. He read the report of the treasurer, Mr. J. B. Taltavall, which showed total receipts up to June 23 of $1,616.25; expenses, $127.22; retainer to Charles Keck, sculptor, $50.00; total expenses, $177.22, leaving a balance on hand of $1,439.03.

Mr. Griffith then read a letter from Mrs. E. H. Harriman, of Arden, N. Y., in which that lady very generously offered to meet the expense of the monument and its cutting. The committee therefore was thus enabled to report the matter closed, which announcement was greeted with applause. Mr. Griffith announced, however, that those present who had not yet subscribed to the fund had the opportunity to do so. He suggested that the association be represented by a committee at the dedication of the monument in the fall. The report was accepted and approved. The correspondence between Mr. Griffith and Mrs. Harriman is published on another page.

A paper on "Line Conductor Requirements for Telegraph Transmission" was read by Mr. F. F. Fowle, of Chicago. The paper was a very comprehensive discussion of the subject and pointed out the effect of line leakage upon operation, which hitherto had not been given as much consideration as its importance warranted.

The effect of leakage was practically demonstrated by means of a simplex outfit. The two terminals of a line were represented by the usual instruments side by side on the same base. These were connected by an artificial line equivalent to an actual line 500 miles in length the leakage and insulation being varied by means of switches. The effect of leakage upon the operation of the line was very clearly demonstrated by means of this apparatus.

Mr. W. Tassin supplemented Mr. Fowle's paper with a description of the methods employed in manufacturing copper clad wire, and illustrated his subject by means of lantern slides showing views of the works of the company manufacturing this wire and micro-photographic pictures of cross sections of copper clad wire showing the complete union between the steel core and the copper covering.

After a vote of thanks to Mr. Fowle the meeting adjourned until Wednesday morning.

WEDNESDAY'S SESSION.

The Wednesday morning session was called to order at 10 o'clock. Messrs. W. W. Ryder, U. J. Fry and W. Marshall were appointed a committee to confer with a like body from the Railroad Telephone and Telegraph Appliance Association in order to arrive at a better understanding of the relations between the two organizations and to discuss matters of interest to both associations.

Mr. J. F. Caskey then read a paper by Mr. John B. Adams on "Telephone Cable Transmission." This paper was a highly practical discussion of the subject and contained basic rules for the determination of telephone transmission, describing the rules in non-technical language. It was based upon original data collected in the manufacture of telephone cables. The paper contained curves of resistance and capacity co-efficients.

"Current Supply for Selective Calling Systems" was the title of the next paper which was read by the author, Mr. W. E. Harkness, of New York. He first considered the number of selectors that can be operated under various combination systems with and without clearing-out signals, and following with a detail consideration of the cost of equipment and annual charges. The paper was

Digitized by Google

discussed by Messrs. J. F. Caskey and W. J. Camp.

Mr. W. Maver, Jr., of New York, then read a paper on "High Speed Automatic Perforators, or Perforator Receivers," which was followed by a highly interesting discussion participated in by Mr. A. G. Saylor, Mr. P. W. Drew and Mr. W. J. Camp.

On motion of Mr. W. J. Camp a vote of thanks was tendered to Mr. Maver for his paper. An abstract of this paper together with the discussion it gave rise to will appear in a later issue.

A paper entitled "Economy in the Telegraph Department," by Mr. Wm. Bennett, of Chicago, was read by Mr. W. F. Williams in the absence of the author, and was followed by a lengthy and interesting discussion, supplemental to which Mr. U. J. Fry, of Milwaukee, described the simplex train dispatchers telephone circuit used on his road. He has five of these circuits between Butte, Mont., and Seattle, Wash., a distance of 656 miles, and is equipping five circuits between Butte and Mowbridge, 720 miles, making a total of 1,376 miles. There is one repeating station between Butte and Seattle. These circuits are now working duplex regularly. In the event of a quadruplex giving out one of these circuits can be used to patch the quad.

After some discussion on Mr. Fry's address, Mr. G. K. Heyer, of New York, read a paper on "Telephone Economy in Railway Service."

After a brief executive session various committees submitted their reports and the subject of the next meeting was taken up. New York, Omaha, Milwaukee, St. Louis, Peoria, Ill., and other places were proposed, but Mr. A. B. Taylor made such an effective plea in behalf of New York that it was voted to hold the 1912 convention in that city, June 24 being the time set.

Amendments to the constitution were submitted by the Executive Committee and adopted. The amendment to Section 2, Article V, relates to the number of members that shall constitute a quorum of the executive committee; that to Section 6, Article V, empowers the presiding officer to appoint a sufficient number of active members to form a quorum of the executive committee in the event of a quorum of that committee not being present at an annual meeting, for the sole purpose of acting upon applications for membership. Section 1 of Article VI was amended to authorize the executive committee to change the time and place of an annual convention from the date originally set, after due notice to the members.

Officers were elected as follows:

President, Mr. G. A. Cellar, Pittsburg; first vice-president, Mr. Wm. Bennett, Chicago, Ill.; second vice-president, Mr. A. B. Taylor, New York; secretary and treasurer, Mr. P. W. Drew, Chicago, Ill.

The new officers, excepting Mr. Bennett who was absent, were then installed and after a few remarks of thanks from each the convention adjourned.

ATTENDANCE.

Active Members.—W. W. Ashald, Montreal, Que.; C. W. Bradley, Richmond, Va.; W. J. Camp and wife, Montreal, Que.; J. F. Caskey and wife, South Bethlehem, Pa.; G. A. Cellar, Pittsburg, Pa.; W. P. Cline, wife and daughter, Wilmington, N. C.; W. L. Connelly and wife, Chicago, Ill.; J. H. Ditch and wife, Altoona, Pa.; P. W. Drew and wife, Chicago, Ill.; L. B. Foley, New York, N. Y.; U. J. Fry, Milwaukee, Wis.; T. R. Gooch and wife, Richmond, Va.; O. C. Greene and daughter, St. Paul, Minn.; E. P. Griffith, wife and son, Jersey City, N. J.; T. M. Haston, wife and niece, Bloomington, Ill.; J. L. Henritzy, Denver, Col.; E. D. Hubbard and wife, Battle Creek, Mich.; J. G. Jennings and wife, Chicago, Ill.; J. C. Johnson, wife and daughter, Philadelphia, Pa.; E. C. Keenan and wife, Cleveland, Ohio; V. T. Kissinger and wife, and Mrs. A. V. Cornish, Chicago, Ill.; C. L. Lathrop and wife, Angelica, N. Y.; L. A. Lee, wife and daughter, Pittsburg, Pa.; C. M. Lewis, Reading, Pa.; M. Magiff and wife, St. Albans, Vt.; W. Marshall, Toronto, Ont.; J. T. Nolan, Washington, D. C.; A. C. O'Brien, Boston, Mass.; G. O. Perkins, Chicago, Ill.; W. H. Potter and wife, Washington, D. C.; C. S. Rhoads, Indianapolis, Ind.; Thos. Rodger, wife and daughter, Montreal, Que.; J. J. Ross, Detroit, Mich.; W. W. Ryder, wife and two sons, Chicago, Ill.; C. Selden, Baltimore, Md.; J. B. Sheldon and wife, Omaha, Neb.; E. A. Smith, Boston, Mass.; N. E. Smith and wife, New Haven, Conn.; A. B. Taylor and wife, New York, N. Y.; B. F. Thompson, Baltimore, Md.; S. L. Van Akin, Jr., Syracuse, N. Y.; F. H. Van Etten, wife and son, Chicago, Ill.; H. A. Vaughan, Lincoln, Neb.; J. M. Walker and wife, Denver, Col.; W. C. Walstrum and daughter, Roanoke, Va.; B. Weeks and son, Memphis, Tenn.; F. T. Wilbur, Chicago, Ill.; W. F. Williams, wife and daughter and Miss Neeley, Portsmouth, Va.; F. S. Work, Warwick, N. Y.;

Associate Members.—E. V. Adams, Chicago, Ill.; G. Brown, New York, N. Y.; A. N. Bullens, Boston, Mass.; W. L. Cook, Chicago, Ill.; W. F. Crowell and wife, New York, N. Y.; Albert Douglas, Chicago, Ill; A. P. Eckert, wife and daughter, New York, N. Y.; H. B. Fenn, Newark, N. J.; E. M. Fisher and son, Nashville, Tenn.; F. F. Fowle, Chicago, Ill.; A. G. Francis, wife and two sons, Chicago, Ill.; M. F. Geer, Rochester, N. Y.; J. J. Ghegan, wife and daughter, New York, N. Y.; W. E. Harkness, daughter and sister, New York; G. K. Heyer, New York, N. Y.; H. Homer, Philadelphia, Pa.; E. E. Hudson, Orange, N. J.; B. A. Kaiser and wife, New York, N. Y.; J. M. Lorenz and wife, Chicago, Ill.; P. W. Miller, New York, N. Y.; Val B. Mintun, Kansas City, Kan.; W. O. Nevill, Kansas City, Kan.; G. W. Peck, New York, N. Y.; C. N. Sigison, New York, N. Y.; G. W. Swan, New York, N. Y.; A. D. Walters, New York, N. Y.; A. Wray and wife, Chicago, Ill.

VISITORS.—Miss M. L. Allison, Chicago; Belvidere Brooks, New York; F. C. Cosby, Boston; D. J. Cavanaugh, Memphis, Tenn.; Mrs. E. A. Chenery, St. Louis, Mo.; R. E. Chetwood, New York; L. E. Dodge, Rochester, N. Y.; W. H. Graffis, Chicago; R. N. Hill, New York; E. A. Hawkins, New York; Richard S. Harris, Pittsburg, Pa.; G. A. Joy, Chicago, Ill.; D. C. Keefe and wife, New York; H. P. Kimball, New York; H. S. Knowlton, Newton, Mass.; Edgar Lowe, Jamaica, N. Y.; R. C. Leake, Rochester, N. Y.; Mrs. G. S. Minot, Brookline, Mass.; J. L. McQuarrie, New York; L. G. Martin, New York; W. C. Merly, New York; E. L. Marshall, Fremont, Ohio; Wm. Maver, Jr., and two daughters, New York; C. S. Rhoads, Jr., Sandwich, Ill.; A. G. Saylor, New York; O. D. Street, New York; R. F. Shamer, New York; A. D. Smith, Montreal, Que.; H. N. Tucker and wife, Boston; Mrs. N. J. Tidby and son, St. Paul, Minn.; T. R. Taltavall, New York; H. G. Thompson, Orange, N. J.

The technical press was represented by Mr. W. H. Graffis of *Telephony*, Chicago; Mr. H. S. Knowlton, Boston editor of the *Electrical World*, New York, and Mr. T. R. Taltavall, of TELEGRAPH AND TELEPHONE AGE.

ENTERTAINMENT.

On Monday evening the members and others attending the convention were entertained at the "Pop" concert at Symphony Hall.

Tuesday morning was devoted to local sight seeing and at 2 p. m. the ladies were taken on an automobile trip along the North Shore. In the evening a trip was made to Revere Beach and everyone enjoyed the diversions offered by this resort.

The entire day Thursday was devoted to an excursion to Plymouth where the party went over the hallowed grounds at that place. The historic rock was naturally the centre of interest. The weather was delightful and the trip was greatly enjoyed.

The entertainment committee deserve much credit for the able manner in which they performed their duties. Each member was around early and late to see that everyone got the utmost enjoyment out of their visit, especially the ladies.

NOTES OF THE CONVENTION.

Mr. Belvidere Brooks, general manager, Mr. A. G. Saylor, general superintendent, Mr. R. E. Chetwood, engineer of construction, and Mr. W. C. Merly, secretary to the general manager, arrived from New York Tuesday morning. Messrs. Brooks, Saylor and Chetwood received a hearty greeting on their appearance at the meeting and were given places of honor on the platform with acting president Sheldon.

Mr. Jasper N. Keller, president, and W. J. Denver, general manager, of the New England Telephone and Telegraph Company, Boston, both old-time telegraphers, were accorded a hearty reception during Wednesday's session and made a few remarks.

Exhibits.

The Okonite Company, New York, was represented by Mr. L. G. Martin.

The National India Rubber Company, New York, was represented by Mr. A. P. Eckert, sales manager, wire department, New York.

The National Carbon Company, Cleveland, Ohio, made an extensive display of Columbia dry batteries, track batteries, and multiple batteries for motor ignition, and distributed a plentiful supply of literature.

The American Telegraph Typewriter Company, New York, had an operating exhibit. The company was represented by Dr. G. A. Cardwell, president; Mr. Allen Cardwell, son of Dr. Cardwell; Col. W. H. Eckert; Mr. H. C. Adam, secretary, and Mr. James Uncles of the engineering department.

J. H. Bunnell & Co., New York, was represented by Mr. J. J. Ghegan, president, who exhibited a Ramsey cable jack or quick switch. This switch was described and illustrated in these columns in a recent issue. Mr. Ghegan distributed as souvenirs a very useful automatic tape measure.

The National Telephone Selector Company, New York, exhibited its new alternating-current, open circuit telephone selector system for train dispatching and its non-grounded simplexing intercommunicating selector system for message circuits. The company was represented by Mr. G. M. Seeley, vice-president, and Mr. E. Kleinschmidt, engineer.

The Holtzer-Cabot Electric Company, Brookline, Mass., had a complete exhibit of H.-C. tubular wire connectors. These connectors are seamless drawn and make perfect self-welding joints that are said to be stronger than the wire itself. The company was represented by Mr. C. H. Gogel, Jr., Southern representative of the company, Baltimore, Md.

The American Telephone and Telegraph Company was represented by Mr. B. A. Kaiser, and G. W. Peck, New York; Albert Douglas, Chicago, and H. Homer, Philadelphia. The Missouri and Kansas Telephone Company's interests were looked after by Mr. Val B. Mintun and W. O. Nevill of Kansas City, Mo., and Mr. A. G. Francis represented the Chicago Telephone Company and Mr. Henry Miller the New York Telephone Company.

The Randall Telephone Manufacturing Company, New York, had a working exhibit of its high power telephone train dispatching transmitter. The Randall telephone train dispatching outfit was also shown.

Digitized by Google

It consists of a high power transmitter on an adjustable arm together with a loud-speaking telephone receiver. This type of receiver does away with the necessity of head gear. Mr. C. Adams-Randall, consulting engineer, New York, and Mr. A. B. Rogers, secretary, Boston, were in attendance and gave practical demonstrations of the operation of the apparatus.

The Western Electric Company occupied parlor "E" and had a complete display of railway telephone and selector equipment. Practically every kind of telephone apparatus used on railways and selector equipment was shown in practical operation. The loud speaking receiver was exhibited on this occasion for the first time and attracted much attention by its clear enunciation. The rotophone transmitter arm was also shown for the first time. Other apparatus displayed included the new semaphore recently developed by the company; transmitters and receivers of various types, portable telephone and pole, etc. Other apparatus shown was a new master selector key, of the push button type, with a capacity of forty stations. It is contained in a box 18 inches long by 6 inches high. The company was represented by Messrs. G. K. Heyer, O. D. Street, E. A. Hawkins, J. L. McQuarrie, O. E. Stephens, R. F. Spamer, of the New York house; Mr. E. V. Adams, of the Chicago house, and Messrs. E. L. Hawkins, W. F. Abley and H. B. Gilmore, of the Boston house.

The General Railway Signal Company, Rochester, N. Y., showed the complete apparatus used in its system of selective signalling. The complete equipment consisted of a selector; a bell, operated by either direct or alternating current; a bank of individual keys; a storage battery consisting of six cells of 80 ampere hour capacity each, and a switchboard on which were mounted all the necessary accessories for the operation of the system. The most unique feature is the means for furnishing current to the line for the operation of the selectors, which consist of a storage battery and a motor generator set. The initial movement of a key in sending a call starts the motor generator set which is so designed that it attains a sufficient speed in a small fraction of a second to boost the battery voltage to line voltage; the final movement of the key in returning to normal position automatically breaks the circuit of the battery and the motor generator. This system it is stated obviates the necessity of a large central station battery and is claimed to reduce the cost of current. The company was represented by Mr. M. F. Geer, sales engineer; Mr. R. C. Leake, assistant engineer, and Mr. Lyman E. Dodge, patent attorney.

The United States Electric Company, New York, had a complete exhibit of the Gill selective calling as applied to railway operation, in telephone and telegraph train dispatching and message service and to the dispatcher-controlled train-order semaphore. A train dispatcher's desk was shown fully equipped for operation and a circuit of ten Gill selector stations was set up in the parlor. The box outfits include selectors on both two-figure and four-figure combinations and for calling by main line and by local battery bells. The new two time-wheel selectors, making a call in three seconds were also shown. For emergency work there was a complete portable dispatcher's outfit. The way station telephone apparatus was shown set in a box and also a leather cased hand telephone set. The selective train order semaphore was a prominent feature of the exhibit. When thrown to "danger" the signal reports itself audibly by induction over the telephone wire and is mechanically locked against clearing until the dispatcher gives electrical permission so to do. This system operates as far as a telegraph impulse may be effective. Other apparatus shown included a phantom coil set in a box and a simplex set. Various testing and protective devices were also shown. The supplies and construction material included samples of Waterbury wire and cable, Universal storage battery, both glass jar and portable types, battery boxes and Matthews specialties. The company's representatives in attendance were Mr. Howard E. Merrell, Mr. Chas. N. Sigison, treasurer, Mr. W. E. Harkness, assistant general manager, Mr. W. L. Cook and Mr. Edward E. Backus, New York.

Railway Telegraph and Telephone Appliance Association.

The Railway Telegraph and Telephone Appliance Association held its annual meeting at the Hotel Brunswick, Boston, June 27, and elected officers as follows:

A. P. Eckert, New York, Chairman; J. J. Ghegan, New York, vice-chairman; W. E. Harkness, New York, secretary-treasurer.

Executive Committee: Messrs. H. E. Merrill, New York; H. O. Rugh, Sandwich, Ill.; W. F. Crowell, New York; W. H. Graffis, Chicago; E. E. Hudson, Orange, N. J., and H. P. Kimball, New York.

Messrs. R. A. Paterson and G. K. Heyer, of New York, and J. M. Lorenz, of Chicago, were appointed a committee to confer with a like committee of the Association of Railway Telegraph Superintendents to make suitable arrangements for accommodations, exhibits, etc., at the next convention.

The association now has a membership of thirty-five.

Mr. W. C. Muir, general superintendent of the Canadian Northern Telegraph Company in renewing his subscription says: "My experience with TELEGRAPH AND TELEPHONE AGE is that it contains a lot of valuable information, and for this reason I have decided to place the publication in the hands of some of our officials as per enclosed list."

The Turner Monument Fund Closed.

Through the generous aid of Mrs. E. H. Harriman, wife of the late E. H. Harriman, the Turner Monument Fund has been closed, and active preparations will now be made to carry the project into execution.

Following is the correspondence bearing on the subject:

JERSEY CITY, N. J., JUNE 22, 1911.

MRS. E. H. HARRIMAN,
Arden House, Arden, N. Y.

Dear Madam: The Association of Railway Telegraph Superintendents and the Old Time Telegraphers and Historical Association, through their committee having in charge the project of erecting a handsome tablet at Harriman station, commemorative of the introduction of the telegraph in railway service, begs leave to solicit your aid in the matter. The committee has already collected a fund of $1,700, which will defray the expense of the tablet and the printing of a souvenir booklet containing a story of the events leading up to Mr. Minot's innovation in railroad operation, as well as an account of the dedication ceremonies and a list of the names of the subscribers to the fund, a copy of which will be sent to all subscribers.

It is desired to procure native stone, as a support for the tablet, and the committee presumes to ask you to contribute the stone from your premises and the necessary cutting to prepare it to receive the tablet. The stone may be in several sections. Full working plans for the cutting will be furnished by the committee.

The general design of the monument indicates the first telegraphic message sent by Professor Morse from Congressional Hall in Washington, to Baltimore, reading "What hath God Wrought," cut in the stone. All the other lettering will be placed on the bronze tablet. There will be shown in the maze of the lettering a reproduction of the original poles, insulators, brackets, switchboards and instruments used by Mr. Minot at Harriman station in 1851. There will also appear a bas-relief of Charles Minot. On the margin or frame of the tablet will appear the usual decorations, illustrative of Light and Wisdom, intertwined in a maze with the tools used by the telegraph linemen. In other words, it will be a distinctively telegraph monument, the only one of its character in the world, and a very interesting and decorative adjunct to the beautiful station grounds.

You will please pardon this intrusion, but the committee feels that you are interested in such matters and they have undertaken to give you a pen picture of the monument as it will appear when completed, hoping that it will appeal to you as worthy of consideration and receive your approval.

We might add, for your information, that the project has received the endorsement of Mr. F. D. Underwood, president of the Erie Railroad, Mr. Andrew Carnegie, Mr. Thomas A. Edison, and many other prominent railroad and telegraph men, who have favored us with liberal contributions.

I am, most respectfully,
Yours truly,
(Signed) E. P. GRIFFITH,
Chairman.

ARDEN, N. Y., June 23, 1911.

MR. E. P. GRIFFITH,

Dear Sir: I have received your interesting letter about the telegraph monument to be put up at Harriman station commemorative of the introduction of the telegraph in railway service. I will be glad to assist in any way possible and will provide the stone as you suggest and the necessary cutting.

Will you please send the full working plans for the support for the tablet to Mr. C. T. Ford, Central Valley, N. Y. He, being my superintendent, will co-operate with you in every way desired.

Hoping to hear that this project will be put through promptly and successfully, I am,

Yours sincerely,
MARY W. HARRIMAN.

JERSEY CITY, N. J., JUNE 24, 1911.

MRS. MARY W. HARRIMAN,
Arden House, Arden, N. Y.

Dear Madam: Your very kind letter of the 23rd instant, in reply to mine on the subject of a telegraph monument at Harriman Station, is received Your prompt and most generous aid, I assure you, is appreciated very much by the two Associations I represent.

You have enabled us to bring the project to a successful conclusion, and our thankfulness is beyond measure.

Yours very truly,
(Signed) E. P. GRIFFITH,
Chairman.

In accordance with this correspondence Mr. E. P. Griffith, chairman of the Turner Monument Fund Committee made the following report at the Boston Convention of the Association of Railway Telegraph Superintendents:

Mr. President: Your committee, appointed at our last annual convention, at Los Angeles, Cal., for the purpose of collecting a fund to erect a monument at Turner, N. Y., station, in commemoration of the first train order issued by telegraph, takes pleasure in reporting that the responses to the committee's appeals have been most generous and through the aid of Mrs. E. H. Harriman, of Arden, N. Y., who has contributed the necessary stone and the cutting of same, we are able to report the matter closed.

We would recommend that this association be represented at the dedication of the monument this fall by a large delegation and that the president appoint a large committee for that purpose.

Yours truly,

E. P. GRIFFITH, J. B. TALTAVALL, C. SELDEN, E. A. CHENERY, W. J. CAMP, W. B. WILSON, F. J. SCHERRER.

Digitized by Google

Mr. Charles Heck, the noted sculptor of New York, has prepared plans for the monument and submitted sketches to the committee in charge of the matter.

Contributions received up to date are as follows: Previously acknowledged, $1,607.25; J. F. Mackie, Chicago, Ill., $2.00; F. S. Work, Warwick, N. Y., $5.00; J. T. Nolan, Washington, D. C., $2.00. Total, $1,616.25.

Physiological Effects of Electric Shock.

The chief causes of death from electric shock, say Drs. Krida and Stanton, in the New York State Journal of Medicine, are undoubtedly "fibrillary" contractions of the heart and respiratory paralysis. By the former are meant incoordinate contractions of the individual muscles of the heart resulting in complete derangement of its normal rhythmic beat. Respiratory paralysis seems to be identical with the results of an overdose of an anæsthetic. Respiration may continue, and consciousness be preserved, in cases of fibrillary contractions, till anæmia of the nervous system causes death, but, if the action of the heart be unimpaired, respiration can frequently be artificially restored. As yet there is no known reliable means of restoring the normal action of the heart once it is deranged; on the other hand, if the respiratory organs are alone affected, prolonged artificial respiration enables a considerable percentage of recoveries from apparent death.

The conflicting results reached by many investigators, as to the physiological effects of electric currents, are chiefly attributable to the different forms of current employed and the diverse experimental conditions. The following remarks apply to cases of shock from circuits carrying amounts of energy such as are used in ordinary commercial work. The current passing through the body of the victim probably varies between ½ and 10 or more amperes.

The effects produced by direct and alternating currents vary directly with the current strength (and hence with the applied voltage), with the duration of contact and with the path of current flow through the body. The frequency of alternating currents is of great importance, low-frequency currents being usually more dangerous than high-frequency currents of the same strength.

Paralysis of the heart is especially liable to result from low-pressure currents, particularly if the heart be in the path of current flow; respiratory paralysis, however, usually follows on anæsthesia of the central nervous system set up by high-pressure currents. Actual destruction of tissues by burning occurs only at the site of high-resistance contacts, and is of minor importance as a cause of death; nevertheless the tissues often slough far beyond the apparent limits of the burn. In cases of accidental shock, the body often serves merely to complete the path of a high-pressure arc.

In general the lower animals are more susceptible than human beings to electric shock. Whereas 70 volts direct current is often fatal to dogs, 100 volts scarcely affects a normal man, 200-400 volts produces muscular cramp, and 550 volts produces almost instantaneous respiratory failure. Low-pressure alternating current shocks are liable to cause fibrillary contractions; 600 volts causes fibrillations and respiratory paralysis, but 2300-4800 volts usually affects respiration alone (in such cases artificial respiration should be persevered with, for hours if necessary). The medical reports of the electrocutions in the United States since 1890 show that a few seconds' flow of 2 to 7 amperes (at 1500 volts, 15 to 50 cycles per second) may not cause death, but with an application of 45 to 50 seconds' duration, the heart's action is permanently suspended.

Lower Cable Rates Discussed at London Conference.

The subject of cheaper cable rates was discussed at the meeting of the Imperial Conference at London, on June 15.

Sir Joseph Ward, Premier of New Zealand, said there was a feeling in the overseas countries that the present rates were due to a ring or combination in the cable world, and Sir Wilfrid Laurier of Canada pointed out that all the trouble which existed at present was in connection with the Atlantic cables. There was, he said, an impression amounting almost to conviction in Canada that a combination existed with regard to the cables.

Postmaster General Herbert Samuel supported a resolution to the effect that it was desirable to obtain a reduction of cable rates throughout the British Empire. After referring to the consent of the principal Atlantic cable companies to a reduction of 50 per cent. for deferred dispatches and expressing hope that with the approval of the foreign administrations interested new rates would shortly be introduced, he announced that steps were being taken with a view to obtaining a reduction of press rates.

After a discussion of the question of nationalizing an Atlantic cable with the object of cheapening rates to Australasia, Mr. Samuel suggested that in view of the probability of a reduction in rates the government would not at the present time be justified in undertaking a large capital expenditure and the risk of loss that would be involved, but he moved a resolution, which was passed unanimously, "that in the event of considerable reductions in transatlantic cable rates not being effected in the near future, it is desirable that the laying of a state-owned cable between England and Canada be considered by a subsidiary conference."

Mr. S. L. Robinson, an old-time and military telegrapher and for years prominent in Chicago telegraph circles in renewing his subscription for another year writes: "While out of the way somewhat up here in northern Michigan, the AGE keeps me in touch with my old associates in the telegraph world and refreshes in my mind pleasant memories. It is very welcome."

The English State Telephone Service.

Replying to criticisms of the project to take over the National Telephone Company's system by the English government, Hon. Herbert Samuel, the British Postmaster-General, said that he failed to see why a private company could operate the telephone system cheaper than could the government, as the money borrowed by the government for the enterprise only paid 3 per cent., while the independent company would have to borrow it at a higher rate. He stated that the government could easily make the telegraph pay at any moment by ceasing to provide telegraphic facilities in rural districts and by abolishing 12-cent telegrams. The lack of efficient service in foreign government systems he stated, was a fault of the service and not of the principle.

Telephone Numbers.

Speaking of telephone numbers, says Ellis Parker in *Judge*, a good number for a cigar dealer would be 2-4-5, and a cheap suburban sport might as well be 4 Flushing as anything else. An Irishman wishing to dine would naturally call up a place 2-8, but a Hinglishman 'aving to call up a blarsted, bloomin' creditor regarding a bill would be '8-2.

A lover ordering a chair would want 1-4-2, and a newly wed couple wishing a flat would want 1-4-2-2, but the German maiden refusing to marry would shout 9-9-9-9. (Oh, how clever!)

If you want to borrow you wish 4-2-0, and probably that is a money lender's number, but if you only want a small loan from a friend you will wish 2-0-5. (That's pretty cute. What?)

The bookmaker should have two 'phones—9-2-1 for long shots and 4-2-5 for favorites. The man with a dog might call 6-6-6-6 (get that?)—and the farmer should put 8-0 on his list. (Put-eight-o, hey, what! I rather guess that's a rotten potato!)

If two horses were in the running and 1-1-5-0 John he would be a happy lad and his smile would be 2-2 Broad. (This is one I 8-2 Spring on you.) And if John spent the cash for liquor I would cry 5-5-5-4 John! But that is just how careless John is. His drinking is hades for his wife, but it's 7-4 John. (What, ho!)

(Honestly, I could keep this up all night!) If two of you wished to be wed you would not have 2-8-4 Spring, because you could call 4-1 Rector to make you one immediately, and then, if tired of being united in one, you could go to a fat judge and let that 1-2 Broad-party-W again. (If you can't see that, ask for information.)

The Brown Telephone Relay in Wireless Telegraphy.

In our issue of March 1 we referred to some experiments made by G. W. O. Howe, assistant professor of electrical engineering at the City and Guilds College, South Kensington, England. The Brown telephone relay played an important part in these experiments and very materially increased the sensitiveness of the receiving equipment.

The aerial at the college consists of a single wire of No. 14 gauge suspended between a chimney stack on the college and the tower of the Imperial Institute. The length of the span between the chimney and the tower is about 530 feet, the upper end being about 260 feet from the ground and the lower end 100 feet. When a Brown telephone relay was introduced between the detector and the telephone receiver signals from Glace Bay, N. S., could be distinctly heard at night, whereas before the insertion of the relay it was not possible to pick up the signals. The aerial is connected through a variable inductance to a transformer with variable coupling. The circuit of the secondary winding of the transformer includes, in series, a zincite-pyrites detector, a variable inductance and the Brown relay, two condensers being bridged across the circuit, one on each side of the detector. With this arrangement the telephone responds so loudly that signals from the Eiffel Tower in Paris and the Norddeich station in North Germany can be heard distinctly all over the large lecture theatre of the college.

Use of Telephone in Surgery Probing.—One of the latest applications of the telephone is its use in surgical work in probing for bullets and other metallic substances in the body. The device is described at length in the *Medical Record* by Dr. William S. Thomas of St. Luke's Hospital, New York. In the search for metallic substances in the body, such as pins and needles, the fine points of the telephone searcher are made to traverse the tissues where the foreign matter is concealed. The general location of the troublesome substance is at first determined by an X-ray photograph. The probe consists of three parallel needles insulated from one another on a handle, and each is connected with the wire of a three-conductor cord. The conductors are connected with a battery and a telephone receiver in such a way that when metallic contact is made with any two of the three points the operator gets a sound through the receiver clasped to his head. Once the grating is heard the operator turns off the switch in order to prevent heating at the point of contact by the electric current. The searching needles are left in position and the surgeon cuts down to where the foreign substance is indicated and removes it.

Mr. A. B. Cowan, commercial superintendent of the Western Union Telegraph Company, Chicago, Ill., in remitting to cover the renewal of his subscription for another year, writes: "I cannot get along without the Age, and wish every man in the telegraph business felt as I do about it. I take every opportunity to recommend it, and see a great many more studying it now than in days gone by. I believe more of the operators are beginning to realize the necessity and advantages of study, and as a consequence in a few years the telegraph service will be on a higher plane than ever."

Lightning Arrester.

The lightning arrester shown in the accompanying illustrations offers a new electrical principle

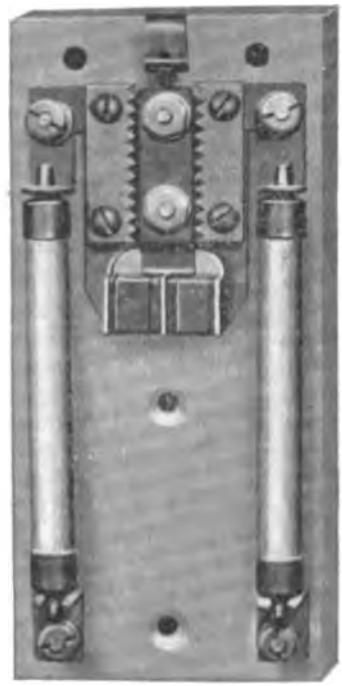

FIG. 1.—NON-AIR GAP LIGHTNING ARRESTER.

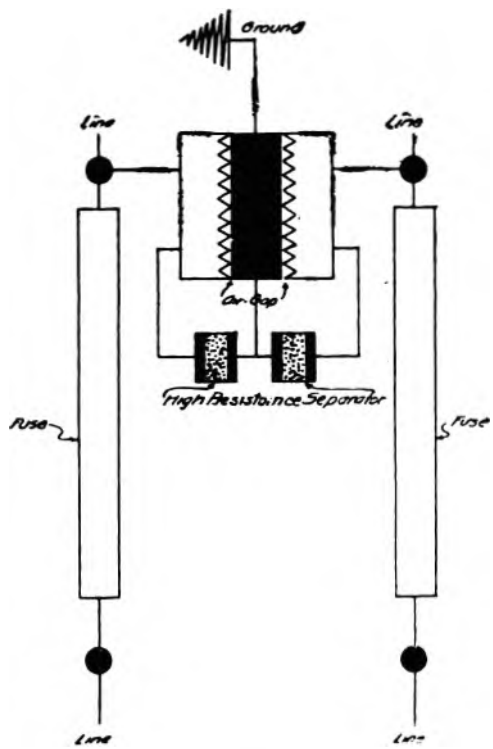

FIG. 2.—DIAGRAM SHOWING CONSTRUCTION OF LIGHTNING ARRESTER. STATIC OR INDUCTIVE DISCHARGES PASS THROUGH HIGH RESISTANCE SEPARATORS. DYNAMIC CROSSES OF 500 VOLTS OR OVER JUMP AIR GAP.

in protection and is the result of a combination of the non-air-gap lightning arrester with a standard telephone type. This combination does away with dusting or fusing of the arrester after lightning storms. Instead of the arc passing across an air gap, causing the metals or carbons to fuse, the discharge is absorbed by a high resistance block between line and ground. The block is of a special material, highly sensitive to static currents but of great ohmic resistance and of constant value. It will not fuse and will permit no leakages of current. The air gap is not done away with as that feature is provided to allow a potential of 500 volts or over to break down and ground thereby protecting the line from crosses with trolley wires or other high potential circuits. The arrester is extremely simple and neat. It was introduced by the L. S. Brach Supply Company, New York, some time ago, and many thousands of them are now in successful service in all parts of the country on signal, telephone and railway telegraph lines.

The anti-dusting lightning arrester is built to conform with the requirements of the National Board of Fire Underwriters and every arrester is tested for efficacy. The capacity of discharge is very great and the arrester is said to be more sensitive than any air-gap type as the resistance blocks themselves are capable of shunting an arc from an air gap of four one-thousandths of an inch in thickness.

Lehigh Valley Installs Telephone Yard Dispatching Circuits.

To expedite the work of handling trains in and about its Jersey City yards, the Lehigh Valley Railroad has applied to terminal operation the methods already employed in dispatching scheduled trains. A telephone system under the supervision of the general yard master, with telephone lines extending to every coal pocket, freight house, yard office, switch and other point with which he is required to keep in touch, has been installed. Western Electric selectors and telephones, with which the rest of the Lehigh Valley's extensive dispatching system has been equipped, are being used. Special equipment was designed for this system.

Telephone Train Dispatching.—The Western Electric Company has just issued a large folding sheet entitled "Our Contribution," which tells its story in pictures. It contains views of the company's train dispatching telephone equipment designed for every requirement of steam and electric railway systems. It also shows views of dispatcher's offices on various prominent railroads using the company's system of telephone train dispatching. It is an interesting record of the work done in this direction.

Hall Signal Company Reorganized.—The Hall Signal Company, at Garwood, N. J., has been reorganized.

Any book on electrical application can be obtained of TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

ANSWERS TO QUESTIONS.

[In this department questions on matters of a practical character, and of general interest, will be answered. Questions intended for this department must be signed by the writer's full name—not for publication, but for identity. No attention will be paid to anonymous communications.]

(47) Q. Has the force of gravity ever been utilized as an aid in the operation of telegraph instruments? It has occurred to me that it might be applied and utilized to good advantage in the construction of apparatus. T. C. O.

A. The force of gravity has been used in this way in the Horton repeater. The bases of the relays are higher at one end than at the other thus throwing the armature lever out of plumb, the force of gravity taking the place of a spring in holding the front contact points closed.

(48) Q. What is a "booster" and what are boosters used for in connection with storage batteries? C. I.

A. A "booster" is a special generator of smaller size than the main generator and is used for automatic control in charging and discharging storage batteries. Boosters are usually driven by direct-connected electric motors.

(49) Q. Is there any advantage in a wireless transformer over an induction coil in the operation of wireless telegraphy? W. T. A.

A. In some respects there is. The strength of the secondary current of a transformer is so much greater than that of an induction coil that more powerful and penetrating waves are developed. On the other hand the secondary of a wireless transformer seldom develops potentials greater than 15,000 to 20,000 volts, while those of an induction coil range from 15,000 to 300,000 volts.

(50) Q. Is sparking at the brushes of generators injurious to the commutator? R. A.

A. Much depends upon the amount of sparking. If it is moderate no harm will result, but if it becomes sufficient in amount or in duration to blacken or roughen the commutator bars, it should be removed as much as possible. The small white sparks along the edge of the brush usually do little injury, but the large ones, appearing at irregular intervals, and with a hissing sound and greenish hue, are more serious. Sparking is not desirable under any circumstances.

(51) Q. Will you please give instructions for the balancing of the quadruplex? Quad.

A. To give these directions in this column would require considerable space. Full instructions for balancing are given in Mr. Jones' book of diagrams and information, and several articles on this subject have been published in recent issues of this paper. The price of Mr. Jones' book is $1.50 per copy.

(52) Q. Please give me the rule to determine the joint resistance of two or more wires. P. G. M.

A. The rule is expressed in the formula, $\frac{R \times R'}{R + R'}$ that is, the joint resistance of two or more wires is equal to the product of the separate resistances divided by the sum of the separate resistances. Thus, giving the letters numerical values, as for example,

$$\frac{20 \times 75}{20 + 75}$$

and performing the operations indicated we have 15.79 as the answer. An easy method of determining joint resistance was published in our issue of February 16 this year.

Outing of Postal Branch Managers.

The fourth annual outing of the branch managers of the first district, Eastern division, of the Postal Telegraph-Cable Company, was held at College Point, Long Island, Saturday, June 24.

The party, numbering 253, the largest gathering in the history of the association, was conveyed to College Point on the steamboat *Orient*, which was chartered especially for the occasion.

There were several races and a baseball game, all of which were hotly contested. Valuable and handsome prizes were awarded to the successful contestants. The fifty-yard dash was won by T. Rahtes; second, Frank Tierney.

The quarter mile handicap run was won by F. Woessner; second, John Henry.

The Fat Men's Race was won by T. J. Donovan; second, J. Hefferman.

The fifty-yard potato race which occasioned much merriment was won by P. Gallagher; second, J. McCauley, and the three-legged race by a team composed of Becker and Eldred, E. Rahtes and Geo. Young finishing second.

The game of baseball was between the general office operators and the branch office men, and was won by the general office operators, the score being 12 to 8. Individual prizes of pearl-handled pocket knives were presented to the winning team.

The walking contest for men in the service over twenty years, which replaced the bowling, was won by Phil. Hickey of the Cotton Exchange office.

In addition to the events originally planned there were the broad jump and shot put for men in the service over twenty years, the former being won by S. E. Ostrom, with W. Finley second; the latter by C. A. Francis, with Chas. Ruffer second.

Mr. C. F. Leonard, district superintendent, New York, was the judge in the contests and he acquitted his delicate duties in a very praiseworthy manner.

Dinner was had at 6:30 p.m., after which the prizes were distributed to the winners of the afternoon contests. The surprise of the evening came when City Manager E. P. Tully arose and with a speech expressing the respect and love in which the association held their superintendent, Mr. C. F. Leonard, presented that gentleman with a large and handsome silver loving cup inscribed:

Digitized by Google

Presented to Christopher F. Leonard
As a token of love and esteem from the
Branch Managers' Association
First District, Eastern Division
Postal Telegraph-Cable Co.
June 24th, 1911

Mr. Leonard responded feelingly, and cordially thanked the members for their good will and thoughtfulness.

An interesting vaudeville entertainment followed and the party returned to the city at 10 p.m. highly pleased with their day's outing.

Following is the list of the officers and committees:

E. P. Tully, Chairman; W. F. Finley, Secretary; H. Zweifel, Treasurer.

Reception Committee.—J. Hennessy, Chairman, J. McCauley, J. Shandley, M. F. Geigle, D. Sullivan, H. J. Reinhardt, J. H. Flood, F. G. Payne.

Committee of Arrangements.—S. E. Ostrom, Chairman, J. F. McNeill, J. A. Manning, H. Weise, C. A. Francis.

Field Committee.—J. J. McDermott, Chairman, T. J. Donavan, T. E. Heffren, T. J. McQuillan, J. Leahey, F. W. Daly, J. F. Tynan, J. J. Alcock.

The success of the affair was unbounded and much credit is due the officers and the various committees for the able manner in which they exercised their duties.

T. M. B. A. Assessment.—Assessment No. 525 and 526 has been levied by the Telegraphers' Mutual Benefit Association to meet the claims arising from the deaths of Horace N. Howell at East Andover, N. H., David R. Downer at East Orange, N. J., Alice M. Walker at North Wilmington, Mass., George H. Schnitgen at Clinton Corners, N. Y., George G. Peckham at Blue Grass, Ia., William H. Barrett at Hugo, Okla., William H. Chisholm at San Francisco, Cal., James H. Rooney at New York, N. Y., Frank P. Burke at New York, N. Y., William A. Dunn at Baltimore, Md., John E. Davhoff at Pasadena, Cal., Robert B. Welch at Woodstock, N. B.

LETTERS FROM OUR AGENTS.

NEW YORK, WESTERN UNION.

In a baseball game on Staten Island, June 17, the Executives beat the Supply Department team 31 to 7. The victors will play a game with the Operators' team at the Morse Electric Club outing at College Point, L. I., on July 8.

Mr. J. C. McGrew, manager of the Jamestown, N. Y., office has been promoted to the managership of the Erie, Pa., office, vice George F. Stadtmiller, appointed district commercial manager with headquarters at Jamestown.

PHILADELPHIA, POSTAL.

General superintendent Mr. E. B. Pillsbury recently visited this office.

Cashier Mr. J. H. Wilson is enjoying a well-earned vacation at the seashore.

Lineman Chas. H. Robey, for many years stationed at Conowingo, Md., was found dead in his barn June 9, having taken his own life.

The great telegraphic song hit,
"SEND ME A NIGHT LETTER, DEARIE."
Good, catchy music; beautiful title design magnificently printed in colors. Title contains night letter. Sung all over New York, 17c. by mail. All popular music sent by mail.
B. L. BRANNAN,
195 B'way, N. Y.

FOR SALE—A Bunnell galvanometer, complete in leather case, with resistance coils and connections for Wheatstone bridge measurements. Must be disposed of immediately to close an estate. Cost over $100.00. Will sell for $35.00. Address "Galvanometer," care Telegraph and Telephone Age, New York.

The Telegraphers' Mutual Benefit Association, 195 Broadway, New York, combines fraternalism with sound business principles; it offers to the telegraph and telephone employe an absolutely safe form of protection, at a cost within the reach of all and lower than can be found elsewhere. Membership is only open to employes in commercial or railroad telegraph or telephone service, and it is manifestly to the interest of those who are eligible and wish to secure life insurance within their means, to secure without delay a certificate for $1,000 or $500, or both, at rates based on present age.

TRANSMITTING MACHINES

I am placing on the market improved YETMAN TRANSMITTING TYPEWRITERS, and KEYBOARD TRANSMITTERS without typewriting features. Am prepared to exchange, repair or rebuild all old machines. Write for catalogues and particulars to

James Uncles, NORTH ADAMS Massachusetts

Rubber Telegraph Key Knobs.

No operator who has had to use a hard key knob continuously should fail to possess one of these flexible rubber key caps, which fits snugly over the hard rubber key knob, forming an air cushion. They render the touch smooth and the manipulation of the key much easier. Price, fifteen cents.

J. B. Taltavall, TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

Every one engaged in telegraphy and telephony should be a constant reader of TELEGRAPH AND TELEPHONE AGE. It gives the latest news in both these fields. Subscribe now. Subscription price, $2.00 per year.

SOME POINTS ON ELECTRICITY.

BY WILLIS H. JONES.

SELF-ADJUSTING RELAYS.

A correspondent writes as follows:

"I notice that single line relays, sounders, and in fact practically all electromagnets used in the telegraph service today are constructed and adjusted by hand in the same way Morse adjusted the first instrument. Now and then I hear of self-adjusting relays, but evidently none of them was satisfactory or it would have been adopted. Can you give us some idea as to what has been done in the way of attempts to invent a practical self-adjusting relay and why every inventor has apparently become discouraged?"

Such an instrument is certainly well worth striving for and the lucky successful inventor would undoubtedly reap a rich financial reward. However, no one has so far succeeded in constructing an instrument of this kind that has filled all requirements with any degree of satisfaction. The whole trouble, in a nutshell, is that the proposition calls for an instrument which, unaided by human intelligence, is required to pit its necessarily permanent or fixed value of retractile spring strength against that of variable force exerted by opposing electromagnetic influences.

For instance, the tension value of the retractile spring is normally a fixed quantity, so to speak, while the magnetic or opposing influence fluctuates in value with every alteration in the volume of current flowing through the coils and line.

There have been many different methods suggested and tried to compensate for alterations in the line current, among which were attempts to accomplish the purpose by placing the armature between the polepieces of two separate magnets, one much stronger than the other, through the respective coils of which the line current flowed in series. The assumption was that any alterations in the current which might develop would not affect the normal working of the armature because the magnetic strength of the two magnets would increase or decrease in the same ratio on each side of the armature.

Obviously this method was unsatisfactory, first, because it required a greater current to offset the back pull, and also because the tension of the retractile spring being still a factor of fixed value did not alter proportionately with the electromagnetic forces created. For this reason the tension spring remained as obstructive in character as ever.

Another method tried was that of connecting a polarized relay in series with the secondary winding of an induction coil through the primary of which the line current flowed. Its operation depended upon the principle that a rising current in the primary will cause the current in the secondary to flow in one direction and a diminishing primary current a secondary current in the opposite direction. When one opens a key in the line on a wet day he decreases the current, even though he may not remove all of it, yet the action is sufficient to throw the lever of the polarized relay over to the "open" local contact point where, of course, it remains until the current of opposite polarity is generated by the closing of the key. As a polarized relay responds to direction of current only, that is, changes of polarity, it follows that the volume of the current is not so important a consideration as are the reversals of polarity. Changes in volume due to wet weather are not rapid enough to affect the armature, hence a readjustment is not required. This relay, however, also proved inadequate. The method was attractive in theory and workable on non-inductive circuits, but was unsatisfactory on long external circuits, subjected to strong inductive influences. Owing to the great sensitiveness of the relay such influences tended to cause the lever to vibrate thus preventing stability of the local contact points.

The latest and probably the most promising self-adjusting relay was that described briefly in the June 1 issue of this journal. We say "promising" because the method is the first we have heard of which endeavors to alter the tension of the retractile spring simultaneously with the fluctuations in the strength of current. Not having seen the apparatus we can only say roughly that this is ac-

Digitized by Google

complished by giving the armature an angular twist which in turn causes the lever and contact points to move bodily into a position where the tension of the spring and magnetic strength of the relay are nearly balanced.

There are, of course, other features in this relay which we have not touched upon, as there are in the previous methods referred to. The point we wish to make, however, is, that there is no use giving up the hope of finally succeeding. Each move in a new direction suggests something else. Some one will no doubt yet solve the problem.

Recent Telegraph and Telephone Patents.

995,619. Selective Signaling Apparatus. To I. F. Manny, Milwaukee, Wis.

995,849. Signaling Device for Telephone Systems. To A. J. Dunton, Ketchikan, Alaska.

995,924. Telephone System. To J. B. Stemm, Chicago, Ill., and G. E. Slade, Brookfield, Mo.

ISSUED JUNE 27.

996,088 and 996,089. Combined Wire and Wireless Telephone System. To M. B. Johnson, San Antonio, Tex.

996,090. Wireless-Telephone System. To M. B. Johnson, San Antonio, Tex.

996,092. Box for Carrying Wireless Signaling Apparatus. To M. B. Johnson, San Antonio, Tex.

996,143. Common-Battery Lock-Out Telephone System. To H. J. Roberts, Evanston, Ill.

996,391. Reinforcer for Telephone Circuits. To E. F. W. Alexanderson, Schenectady, N. Y.

996,445. Telephone Relay and System. To E. F. W. Alexanderson, Schnenectady, N. Y.

Personal.

Mr. Thomas A. Edison has been elected an honorary member of the Automobile Club of Paris.

Colonel Robert C. Clowry will sail for Europe on the steamer *Oympic*, on July 26, to be absent two months.

Mr. Melville E. Stone, general manager of the Associated Press, New York, has received the degree of Doctor of Laws from Wesleyan University.

Major Joseph Orton Kerbey, an old-time and military telegrapher, and ex-consul of the United States to Brazil, has returned from a trip to the Amazon country in Para, Brazil.

Mr. C. H. Murphy, general superintendent of time service, New York, is the subject of a biographical sketch in the Cedar Rapids, Iowa, *Saturday Record*, of July 8. Mr. Murphy is well-known in Cedar Rapids.

Mr. Frank B. Knight, the well-known old-time telegrapher and now special agent in charge of publicity, Southwestern Telephone and Telegraph Company, Dallas, Tex., sailed on July 11, for Paris, where he will meet his daughter. Mr. Knight will return about November 1.

Mr. Ralph W. Pope, an old-time telegrapher and for the past twenty-six years secretary of the American Institute of Electrical Engineers has resigned and will, on August 1, become honorary secretary of that organization. Mr. Pope has been largely instrumental in the up-building of the Institute and has a wide acquaintance in scientific circles both at home and abroad.

Mr. Rupert F. Fry, a former telegrapher and a son of Mr. U. J. Fry, superintendent of telegraph, Chicago, Milwaukee and St. Paul Railway, Milwaukee, Wis., is president of the Old Line Life Insurance Company of America, Milwaukee. Mr. Fry organized the company in 1909 and it was chartered in 1910. It has had a very successful career and has over $1,000,000 insurance now on its books.

Postal Telegraph-Cable Company.

EXECUTIVE OFFICES.

Mr. E. J. Nally, vice-president and general manager is absent on a short sea trip to Nova Scotia, New Foundland and Montreal. He is accompanied by Mr. Theo. L. Cuyler, Jr., assistant treasurer.

Mr. Leona Lemon, division superintendent, New York, is absent on a vacation at Beach Haven, N. J.

Mr. D. McNicol of the electrical engineer's staff, New York, has returned from a vacation which he spent in Canada and in the Thousand Islands region.

Mr. D. H. Gage, jr., of the electrical engineer's department, New York, has returned from Dallas, Tex., where he has been for several weeks engaged in the work of establishing offices for the new Mackay Telegraph and Cable Company, in Texas, Oklahoma, etc.

Mr. S. J. Pickering, manager of the Lebanon, Pa., office of this company, has been transferred to Easton, Pa., as manager.

Mr. W. B. Stewart has been appointed manager of the Asheville, N. C., office of this company.

Mr. W. L. King, manager at Elmira, N. Y., and Mr. G. H. Mills, manager at Providence, R. I., were recent executive office visitors.

Mr. J. C. Carmody, manager of the Fitchburg, Mass., office of this company has resigned on account of ill health and has been succeeded by Miss Bertha M. Atkins, formerly assistant manager.

Telephone Lines on Postal's Poles.

The Postal Telegraph-Cable Company has decided to allow independent telephone companies to string wires on its poles on certain conditions.

The following instructions on the subject have been issued to all superintendents of the Postal system by Mr. E. J. Nally, vice-president and general manager:

"In order to increase our facilities and create a new source of income, our company has decided to make an offer to independent telephone companies of allowing them to string wires on our poles at

Digitized by Google

the usual rental, varying, according to the different localities, from $4 to $6 per mile, per wire, per year, on the condition that we shall be allowed to composite their wires so strung on our poles where it will not interfere with their telephone use, and that we shall be allowed without charge to use the telegraph circuit whenever we wish.

"We have at various places telephone circuits which we can lease at once, and are willing to lease to responsible independent telephone companies. At other places we have copper wires which can be transposed, and we are willing to lease the telephone side of these wires. In all other places we are willing to string copper wires at our own expense, on our own poles, and lease the telephone side of the circuits to responsible independent telephone companies, provided; first, that the telephone company will in each instance contract to keep the lease for five years; and, second, provided that the wires will probably be of use to us upon the termination of the lease—in other words—between commercial centers."

Mr. Frederick W. Conger, division superintendent of the Mackay Telegraph and Cable Company, with headquarters at Dallas, Tex., is one of the most able and progressive officials in the company's service, and his recent transfer from the Postal Telegraph-Cable Company's service at Chicago to that of the recently organized Mackay Company at Dallas is indicative of the care exercised by the company in selecting officials to fill positions requiring ability and tact. Mr. Conger was born in Phœnix, N. Y., in 1855. He learned telegraphy on the Chicago and Northwestern Railroad in 1874 and entered the service of that company as night operator at Westside, Iowa. After serving as extra station agent and operator at nearly all stations between Boone and Council Bluffs for about two years, he became superintendent of telegraph of the Sioux City and Pacific Railroad. In October, 1878, he left this position and became train dispatcher on the Chicago division of the Illinois Central. In July, 1886, he was made chief clerk of the telegraph department and assistant to the superintendent of telegraph of that system, the late C. S. Jones, which position he held until he entered the employ of the Postal Telegraph-Cable Company as clerk in the Chicago office in 1893. He was subsequently appointed chief clerk in the general superintendent's office in Chicago, and in 1899 became superintendent of the same interests at Cincinnati, Ohio, holding this position until April, 1901, when he was advanced to the post of district superintendent at Chicago. In April, 1909, Mr. Conger was appointed superintendent of the western division with headquarters at the same point, which position he held until his recent transfer to Dallas for the Mackay company. Mr. Conger has charge of the Mackay company's lines in Texas, Oklahoma, etc., and is well fitted by reason of his large experience to conduct the affairs of the newly organized interests.

F. W. CONGER,
Division Superintendent Mackay Telegraph and Cable Company, Dallas, Tex.

Conference of Great North Western Telegraph Officials.

A conference of the principal officials and local managers of the Great North Western Telegraph Company was held at Toronto, Ont., on June 27 and 28, when a number of matters in reference to the service of the company were discussed. Mr. George D. Perry, general manager, presided, and among those present were Messrs. S. B. McMichael and D. E. Henry of the general manager's department, A. C. McConnell, secretary and auditor, W. J. Duckworth, superintendent of construction, A. R. Porte, superintendent, Ogdensburg, and managers George Hogarth, Toronto, L. S. Humes, Montreal, Charles E. Davies, Ottawa, C. E. Lillie, Quebec, J. Padington, Winnipeg, J. Jamieson, Hamilton, D. Adams, London, and C. E. McManus, circuit manager, Toronto. It was felt by those present that a great deal of benefit would result from the discussions, which were carried on in a most harmonious manner. The general manager entertained the party for dinner at the Royal Canadian Yacht Club, Toronto Island, and a most enjoyable evening was spent.

Mr. J. J. Barnett, manager, Postal Telegraph-Cable Company, Knoxville, Tenn., writes: "In short the TELEGRAPH AND TELEPHONE AGE gives 'value received' and hence it is always a pleasure to send you my renewal."

Mr. R. C. Bliss, manager Western Union Telegraph Company, Cincinnati, Ohio, writes: "Age improves some things and I am convinced that whoever gets the TELEGRAPH AND TELEPHONE AGE will improve."

Western Union Telegraph Company.

EXECUTIVE OFFICES.

The degree of Doctor of Laws has been conferred upon Mr. Theo. N. Vail, president of the American Telephone & Telegraph Company and of the Western Union Telegraph Company, by Dartmouth College, at Hanover, N. H.

Mr. A. G. Saylor, general superintendent, New York, spent the Fourth in Maine.

Mr. W. E. Athearn, engineer of equipment, New York, is spending the summer at Martha's Vineyard, Mass.

Mr. W. J. Dealy, general superintendent of the Commercial News Department, New York, has gone to the Adirondacks to recuperate after his recent illness.

Mr. Owen A. Conner, manager of the Boston office of this company, was married in Brooklyn, N. Y., on June 21 to Miss M. K. Macdonald formerly of Chicago and for several years private secretary to Mr. E. M. Mulford, division commercial superintendent, New York.

Mr. Wm. E. L. de la Motte, for the past thirty-eight years manager of the Marine Observatory of the Western Union Telegraph Company at Sandy Hook, N. J., has retired from active service. He has been succeeded by Mr. E. Zilly who was for many years Mr. de la Motte's assistant.

Mr. E. Ford Collins for several years past manager of the Pittsburg office of this company has been appointed district commercial manager for the West Virginia territory with headquarters at Huntington, W. Va. Mr. Collins succeeds Mr. S. V. King who has returned to Charleston, W. Va., as manager.

Mr. S. V. King has resumed the position of manager of the Charleston, W. Va. office. He succeeds Mr. H. S. Barbee who has gone to Pittsburg for the same company.

Mr. J. H. Purnell for nearly half a century manager of the Opelika, Ala., office of the Western Union Telegraph Company has retired. He is succeeded by Miss Laura Newsome of Gibson, Ga.

Mr. George Heldorfer, manager of the Western Union Telegraph office at Burlington, Iowa, has resigned after a service of over forty-three years in that place.

Mr. J. C. Strickland has been promoted from the managership at Charlottesville, Va., to be manager at Petersburg, Va., vice Mr. P. L. Wilcox, who leaves the service.

Mr. A. B. Robinson of Wilmington, N. C. has been appointed manager at Charlottesville, Va., vice J. C. Strickland.

Mrs. A. P. Meade has been appointed manager of the Tuscaloosa, Ala., office of this company.

Mr. Frank U. McMullan, manager of this company's office at Greenville, Ala., has resigned after a service of fifty-five years.

The Western Union Telegraph Company and the Postal Telegraph-Cable Company of Texas have signed contracts for the exchange of business.

The annual meeting of the Maine Telegraph Company was held at Bangor, Me., June 24. Directors were elected as follows: Mr. Theo. N. Vail, G. W. E. Atkins, A. R. Drewer, Belvidere Brooks and J. B. Van Every, of New York, and Charles E. Bliss and John Wilson of Bangor, Me.

The Western Union Telegraph Company has made application to the New York Stock Exchange for the listing of $1,877,000 5 per cent. bonds of the Mutual Union Telegraph Company. These bonds will mature in 1941.

Mr. J. C. McGrew whose appointment as manager of the Erie Pa., office of the Western Union Telegraph Company was announced in our issue for July 1, was born in Marietta, Ohio, November 28, 1882, and began his telegraphic career as operator at Mt. Clemens, Mich., in 1903. He afterwards occupied positions as operator at Parkersburg, W. Va., Cincinnati, Ohio, and Erie, Pa., and as wire and repeater chief at Butler, Pa., and at Wheeling, W. Va., which latter position he held for two years. He was appointed manager of the Jamestown, N. Y., office two years ago and held that position at the time of his recent appointment to the managership at Erie.

Meeting of Managers at Indianapolis.

A meeting of managers of the sixth district, Western Division, Western Union Telegraph Company, was held at Indianapolis, Ind., on June 28 last and was presided over by District Commercial Superintendent Mr. A. C. Cronkhite. The object of the meeting was to discuss the new routine for the purpose of forming plans for a concerted solicitation of business and exploitation of new features of the service. Among the managers present were: Messrs. P. L. Mounce, Indianapolis; R. E. Scorah, Terre Haute, Ind.; A. A. Burr, Richmond, Ind.; W. E. Jarvis, Muncie, Ind.; F. J. Rhorer, Marion, Ind.; Chas. Massena, Logansport, Ind.; Howard K. Armstrong, Anderson, Ind.; M. H. Hutton, Kokomo, Ind.; C. W. Mason, Marion, Ohio; F. W. Booher, New Castle, Ind.; J. E. Riley, Bloomington, Ind.; J. R. Sample, Bedford, Ind.; J. J. Lash, Columbus, Ind.; F. M. Andres, Peru, Ind.; W. W. Born, Kenton, Ohio; S. A. Rhodes, Bellefontaine, Ohio; J. P. Freeman, Frankfort, Ind.; C. E. Machir, Piqua, Ohio; M. A. Ryan, Urbana, Ohio; G. W. Morton, Sidney, Ohio.

District Traffic Superintendent Mr. A. A. Montgomery of Cincinnati, Ohio, was present and complimented the managers upon their splendid work. He urged the closest co-operation of the commercial and traffic employes and the necessity of constant supervision on the part of managers at offices where chief operators are not employed. Division Commercial and Traffic super-

Digitized by Google

intendents M. T. Cook and W. J. Lloyd, of Chicago, offered words of encouragement and praise which added materially to the enthusiasm of the meeting. There are seventy-one offices in the district and it is proposed to hold other meetings until every manager has been given the advantage of attendance.

The Cable.

Mr. H. D. Windeler of the Commercial Cable Company's station at Canso, N. S., has been appointed superintendent at St. Johns, N. F., of the same interests.

The Commercial Cable Company's steamer, *Mackay Bennett* has completed the repairs to the cable between Port aux Basques, N. F., and Canso, N. S.

The French Telegraph Cable Company's New York employes held their annual outing on July 2 at College Point, L. I., N. Y. Mr. E. C. Sweeney, traffic manager, was the honorary president.

Obituary.

Mr. W. P. Scully, manager of the Western Union office at 91 Wall Street, New York, died on June 29.

Mr. W. N. Eastabrook, a prominent business man of Elmira, N. Y., and a former telegrapher, died in that city June 30 at the age of 64 years. He was a member of the Old-Time Telegraphers and Historical Association, and was one of the organizers and for several years vice-president and general manager of the New York & Pennsylvania Telephone & Telegraph Company, which afterwards passed into the control of the Bell interests.

The Telephone.

New Exchange in New Orleans.—The Cumberland Telephone and Telephone Company has opened a new exchange in New Orleans and it has been named the "Galvez Exchange" in honor of a former Spanish Governor of Louisiana.

The Telephone in Hot Weather.—During the recent hot spell the use of the telephone jumped to a high limit. Business men and subscribers generally preferred to transact as much business as possible by telephone rather than go out of doors, many merchants remaining at home.

Organization Changes in New York Telephone Company.—Mr. T. P. Sylvan has been appointed assistant to the vice-president of the New York Telephone Company, New York, his former position of special agent, commercial department, having been abolished. Mr. S. M. Greer has been appointed Metropolitan manager with headquarters at New York. Mr. W. W. Nicholson, division general manager, New York Telephone Company, New York, has resigned to become president of the Rochester, Syracuse and Utica Telephone Company. Mr. D. C. Cox has been appointed division general manager, Central Division, and Mr. H. W. Drake has been appointed division commercial manager, Long Island Division.

The Telephone Society of New York.—The 129th meeting of the Telephone Society of New York was held at the United Engineers' Building, June 20. Mr. P. O. Coffin, Auditor of Receipts, New York Telephone Company and the Bell Telephone Company of Pennsylvania and Controlled Companies, addressed the Society on the subject of "Plans and Aims of the Accounting Department." The retiring officers were unanimously re-elected, and these, with the Executive Committee, are as follows: President, E. S. Bloom, American Telephone and Telegraph Company, vice-president, D. C. Cox, New York Telephone Company; secretary-treasurer, T. H. Lawrence, New York Telephone Company.—Executive Committee, J. H. Colket, B. Foraker and J. C. Lynch, New York Telephone Company; W. J. Higgins, Western Union Telegraph Company; F. B. Jewett, American Telephone and Telegraph Company; C. A. Merrill, Western Electric Company.

Mr. Vail Favors Public Control.

Mr. Theo. N. Vail, president of the American Telephone and Telegraph Company and of the Western Union Telegraph Company, says:

"I am not afraid that the public will go far in an attempt to wrest from the corporations their rights.

"I am not afraid if a body representing the people and elected by them or else appointed by the President or by Congress, as the case might be, should take up the judicial problems which must be met by all great utilities, that they would suffer in consequence.

"What I am afraid of are the demagogues and unprincipled politicians who would have the people believe they are continually being cheated by the railroads and the gas companies and the telephone companies.

"It is from men of this class that I should like to see all power taken away. If the people themselves should obtain the right of control there would be no further cause for fear.

"Whether it would be possible under the present conditions and with the present state of interstate commerce laws to inaugurate a national utilities commission I am not prepared to say, but I believe this will be the ultimate solution of the problem. Perhaps in the beginning a State board would do this work much as the railroad commission does its work.

"Public control or regulation of public service corporations by permanent commissions has come to stay. Control or regulation exercised through such a body has many advantages over that exercised through legislative bodies or committees.

"The permanent commission will be a quasi-judicial body. It should be made up of members whose duty it will be and who will have the desire, the time, and the opportunity to familiarize themselves with the questions coming before them.

"It should act only after thorough investigation and be governed by the equities of each case. It would in time establish a course of practice and precedent for the guidance of all concerned.

Digitized by Google

"Experience also has demonstrated that this supervision should stop at control and regulation and not 'manage,' 'operate' nor dictate what the management or operation should be, beyond the requirements of the greatest efficiency and economy.

"Management or operation requires intimate knowledge and experience, which can only be gained by continuous active and practical participation in actual working, while control or regulation can be intelligently exercised after judicial hearing by those who have not the knowledge or experience to operate.

"In other words the commission would be able to pass its judgment upon matters of justice and fairness rather than upon matters of technical detail, just as a judge altogether unacquainted with mechanics may hear a patent case and render a fair decision upon it.

"State control or regulation should be of such a character as to encourage the highest possible standard in plant, the utmost extension of facilities, the highest efficiency in service, rigid economy in operation, and to that end should allow rates that will warrant the highest wages for the best service, some reward for high efficiency in administration and such certainty of return on investment as will induce investors not only to retain their securities but to supply at all times all the capital needed to meet the demands of the public.

"Such control and regulation can and should stop all abuses of capitalization, of extortion or of overcharges and of unreasonable division of profits.

"It is largely the abuse by professional speculative promoters and swindling security vendors, mostly on a comparatively small scale, but not in any way associated or connected with the general business organizations or systems, that has been the cause of most of the popular odium surrounding the necessary machinery of business.

"It is conceded that as a rule private management is better, more economical and more efficient than public management and much more advanced and enterprising. The economical margin between public and private management has been shown by experience to be more than sufficient to secure the best private administration.

"When through a wise and judicious state control and regulation all the advantages without any of the disadvantages of state ownership are secured state ownership is doomed.

"State control of public utilities should not prevent progress, should be sufficiently unrestricting to encourage the introduction and demonstration of the value of any new or novel enterprise, and should allow sufficient reward for the initiative, enterprise, risk and imagination of the adventurers behind such enterprises.

"It should discriminate between the useful adventurers or promoters, pioneers in fact, and those pirates or sharks who on strength of other successes extravagantly capitalize undeveloped ideas and exchange the worthless securities for the savings of deluded and credulous investors. Corporate control and restriction should always exist to a sufficient degree to prevent such speculative promoting and such stock jobbing schemes."

The Nine Hour Law in Ohio.

One of the effects of the nine hour law in the State of Ohio is the throwing out of employment many of the women operators. In order to serve the public, the telegraph office must be kept open longer than nine hours and with women operators under the law this is impossible. It is the purpose of the telegraph companies to find employment for the women operators in other states as far as possible. In some offices they will be retained on a nine hour day, but it is said that as they will not be permitted to work overtime in the rush hours they will be replaced by men on whose working hours no time limit has been placed.

Telegraph Extension in China.

The Chinese telegraph administration, in view of the close working arrangements with the eastern extension, Australasia & China Telegraph Co. (Ltd.), British, and the Great Northern Telegraph Co. (Ltd.), Danish, has concluded an agreement with the two last-named companies whereby it is to receive an advance of $2,433,250 on the foreign traffic dues of the next eighteen years; that is, the two companies are to have as security a lien on the balances payable by them on the Chinese telegraphs under the joint-purse agreement of July 11, 1896. This agreement and, in fact, all other existing agreements and concessions between the administration and the companies were extended to December 31, 1930. It is stipulated that the money is to be utilized only for the development of telegraphs and telephones, and that the telegraphic charges on the land lines in China should be restricted to ten cents Mexican (4⅓ cents American currency) per word for all points within a province and 14 cents (6 cents American) per word between all points within two adjoining provinces.

Automobile Wireless Telegraph Plant.—The Austrian War Office has lately added an automobile wireless telegraph plant to the equipment of the Military Railway and Telegraph Corps. The wireless telegraph outfit, which is on the Siemens and Halske system, is carried on a special 28-32 h. p. chain-driven car. The petrol motor, which is provided with an automatic speed governor, is so arranged that it can be either connected up to the driving mechanism of the vehicle or coupled up to an alternating-current generator and a direct-cirrent exciter used in connection with the wireless telegraph installation. The mast is made telescopic, so that it can be carried on the roof of the car; when extended it measures 98 feet. In addition to the driver, accommodation is provided for six passengers.

Interstate Commerce Commission Decision.—The Interstate Commerce Commission at Washington has ruled that it has no jurisdiction over claims or damages due to alleged errors in the transmission of telegrams.

Some Hints.*

BY W. J. CAMP, ELECTRICAL ENGINEER, CANADIAN PACIFIC RAILWAY COMPANY'S TELEGRAPHS.

Mr. Walstrum, the very persistent Chairman of the Topics Committee, requested me to write a paper for this annual meeting. I pointed out to him the fact that I am not qualified to prepare a paper which would really be of any benefit to this organization. I have at former meetings made some crude attempts, but the only reason why these were received with any attention was because I was fortunate enough to bring up subjects which happened to be of particular interest at the time. My papers were very incomplete, and were simply intended to induce discussion from which I would derive some benefit myself.

On looking over the minutes of previous sessions, I find that nearly every conceivable subject which can interest the members of this Association has already been thoroughly and ably written up, and there is really nothing left for me but to furnish some "hash."

INSULATORS.†

During the period from 1887 to about 1898, the Canadian Pacific Railway Company used white porcelain insulators on a portion of the long through wires. These were of German or British manufacture. An elaborate series of tests proved their great superiority over glass from a mechanical standpoint, the average blow necessary to break a porcelain being three times that required to break the glass insulator. It was also discovered that usually a porcelain insulator was only partially destroyed when hit by a stone and that the wire was not set free and remained fastened to each pole, but the glass insulator was so badly shattered that the wire would be freed and this frequently resulted in a cross with other wires which remained attached to the pole. This advantage was offset to some extent by the fact that, on account of the porcelain insulator being white, it offered a much better mark and was the one aimed at. The price of the porcelain insulator was increased until it reached about nine cents each laid down in Montreal, and its use by us, therefore, abandoned for some years. The glass insulator with which we were supplied then depreciated in quality, apparently on account of improper annealing, and appeals or complaints to the manufacturers resulted in no improvement; and, as the cost of the porcelain insulator was again very largely reduced, we have purchased nothing but white porcelain for the past three years.

Last year we procured porcelain insulators from Canada, the United States and Germany. One make turned out to have defective insulation properties, and we had a series of tests made comparing the three manufactures and glass. All of the insulators were of the same pattern and dimensions. One dozen insulators of each make, selected at random, were placed on pins in the open air, and frequent readings taken of insulation, humidity, temperature and barometer. During the tests the weather was of nearly every description, from dry cold to sleet, wet snow and rain. These tests proved that in every respect the German and United States insulators had from 5 to 10 times the insulating qualities of the Canadian and glass insulators, the two former giving practically the same results with a slight difference in favor of the German and the Canadian porcelain and glass almost on a par. Tests of wires after erection show the same differences.

TRANSPOSITIONS.

The first telephone dispatching circuit we installed was transposed every half mile. The selectors were in series, alternating on each wire. The circuit was found to be slightly noisy, and we then transposed it every quarter mile, which cut down the noise for a time, but we found it almost impossible to keep the circuit free from noise while working the selectors in series; and, as we found that most of the failures were due to the contact points of the relay, we changed from series to main line bridging selector without relay. Since then the circuit has been practically free from noise, and on all subsequent circuits installed the same method has been followed. We now transpose all our dispatching circuits every quarter mile, except where two circuits parallel each for a portion of the way. Over this section one circuit is transposed every quarter mile, and the other every half mile. Looking forward to the time when the telephone will be used for other work, we arrange transpositions on our copper telegraph wires (and sometimes on the iron), every half mile for the first pair, and for the second pair, every mile, or transposed at the quarter, three-quarter, and mile, skipping the half mile.

Our method of transposing when the two wires are on the same arm, is by the use of a curved iron bracket under the arm, and so placed that the wire it carries comes directly under the wooden pin carrying the other wire over the top of the arm. Where the two wires are on separate arms we place an extra pin on the upper arm half way between two of the regular pins, and skip the pin on the lower arm. By these methods we have largely decreased the liability of crosses in case of broken insulators.

LIGHTNING PROTECTION.

The problem of adequate lightning protection is a most serious one with the Canadian Pacific Railway on the portion of the line between Lake Superior and the Rocky Mountains on account of the excessive severity of the lightning in this district. If we use sufficient arresters to take care of the heavy discharges, we most likely will kill the telephone circuit by having so many "traps for bugs." We have been using in the stations where the telephone line is looped four Argus arresters, without fuses, on the four ends of the wires, and two Argus arresters with fuses on the bridge wires to the telephones and selector.

At stations where the circuit is only legged in we

*Paper read at the Convention of the Association of Railway Telegraph Superintendents, Boston, June 26-30.

†Valuable articles on Insulators were published in our issues of January 16 (page 85) and March 16 (page 235).

Digitized by Google

have two Argus arresters with fuses. At the despatcher's office, besides the Argus arresters we equipped the first three poles from the office with O'Connell pole arresters. In some sections this protection seems to be adequate, the circuit being worked right through storms, but in the district mentioned it does not appear to be sufficient, my reports showing that at times the telephone has to be abandoned for an hour or more on account of lightning. There have been some interruptions on account of the pole arresters, and this year we are trying out another make of office and pole arresters to the same extent as the former equipment. Some of our superintendents have asked for pole arresters at every station, but I am afraid that if such were installed they would prove to be an endless source of trouble and annoyance, and that after every severe lightning storm, the circuit would be out of commission until a lineman could be sent over it.

TELEPHONE INSPECTORS.

On the Canadian Pacific system we have one telephone inspector for 250 to 300 miles of circuit with his headquarters approximately in the center. Up to the present we have not found it necessary to provide the inspectors with motor cars, but, personally, I believe that every inspector should have a light motor car, particularly in sections where there are comparatively few trains. Our inspectors are supposed to be continually on the move. I consider that an inspector's duty is not so much to remove interruptions, as to prevent them occurring.

TRAIN TELEPHONE SETS.

On every section where we install telephone train dispatching circuits, we equip every train with a telephone outfit, without selectors. The wrecking cars are provided with howler receivers, by means of which the dispatcher can call them in on the line if necessary. The connecting pole we use is the invention of Mr. J. F. Richardson, superintendent of telegraph of the Eastern division of the Canadian Pacific Railway. It is so arranged that connection can be made with any two wires on the line, no matter whether they are on the same arm or not. We do not install any equipment at outlying sidings as the train equipment answers every purpose should a train become stalled anywhere. On account of the severity of our climate during a portion of the year, no one could use a telephone at a pole box, and each outfit contains sufficient flexible twin wire to lead the circuit into the baggage car or conductor's caboose.

The Turin International Electrical Congress.—The International Congress of the Applications of Electricity, to be held in Turin, Italy, September 10 to 17, will be divided into eight sections, Section VI relating to telegraphy and telephony. Among the subjects assigned for discussion by invited speakers are: "Wireless Telephony," by V. Poulsen, of Denmark; Long Distance Wire Telephony," by F. B. Jewett, of the United States; "Automatic Telephone Exchanges as a Means of Economy and Improvement in Telephonic Communication in Large Cities," by H. Milon, of France; "Research on Secrecy in Wireless Telegraphy," by P. O. Pedersen, of Denmark; "The Various Systems of Multiplex Telegraphy," by W. A. J. O'Meara of England.

Resonators.

BY J. S. KNAPP, BUFFALO, N. Y.

I note the introduction of the new Western Union resonators and desire to say that while the metal support and its rigid base, together with the swinging arms, are a great improvement over former attempts at mounting resonators, it is unfortunate that in designing the wooden resonator no thought was apparently given to the production of a sharp clear sound from the sounder, which is of vital importance. As it now is the sound is deflected upward, entirely away from the ear. True, a part of the sound is heard, but much of it is not. It is bad enough when working on a duplex or quadruplex unincumbered by branch offices, but when one or more branch offices are cut in, they naturally draw so much current away from the main office sounder that the latter does not respond to an adjustment satisfactory to the receiver, especially be he slightly deaf.

Now, as everyone knows, when a cornet player for instance turns his instrument upward or away from an audience, the notes are mellow and in some cases extremely indistinct, while, when he points the bell of his instrument directly toward the audience, the full volume of the sound is readily heard.

The sounder has a brass base plate mounted upon a wooden surbase, to give it a clear sharp sound. Whichever way the full surface of this metal base is turned, that direction will give the greatest volume of sound; hence it will be readily understood that if it is so placed that its entire surface is turned toward the ear, very little sound will be lost and the ease of receiving will be greatly increased.

So much for the law of acoustics. Now let us take up the subject of gravity. Mounted as the sounders now are, with the armature in a horizontal position, gravity cuts but little figure, but to properly mount a sounder in a resonator to obtain the best results, it must be hung in the resonator box upon the end of the base, with its armature in a vertical position and the free end of the armature at the bottom. This will put the gravity pull in only one place, i. e., at the bar upon which the armature hangs. If mounted in the reverse position, it will be readily understood that the force of gravity will be exerted in three places, i. e., at the supporting points of the bar and it will also be endeavoring to pull or swing the armature either backward or forward during the time when the armature is exactly upon the center or when there is no magnetic pull from the sounder coils. Hence the proper position is as mentioned.

The resonator should be made of hard wood and should be built square, so that its four sides will throw the sound directly to the ear. This style

Digitized by Google

of resonator can be readily mounted upon the new resonator arm at no more expense than the present "A" shape resonator.

Economy in the Telegraph Department.*

BY WILLIAM BENNETT, CHICAGO, ILL.

During these times when so much is being said about economy, efficiency and conservation of various forms of energy, it might not be amiss to consider some of the ways that savings may be effected in the telegraph department as related to other departments.

There are several methods: One is by cutting down the volume of business, which method is being adopted to some extent with more or less gratifying results. It has been demonstrated in some instances that the use of the telegraph service has been abused, and that many messages were sent by telegraph which could have been forwarded by mail, accomplishing about the same results. There is a question, however, about this system of saving, as there is no adequate method of determining where to draw the line and the elimination may be carried to such a point that the actual saving would more than be offset by losses sustained, due to delays. If the mail and wire messages could be classified so that the most appropriate service would be rendered, this system could be worked out very satisfactorily; but the business cannot readily be so classified and, consequently, there are objections to the method.

Another method has been considered: that is to close some of the offices and thus cut down expenses. There is always a question as to the wisdom of such a course, under ordinary conditions, as, while a saving may be shown in operating expense an actual loss may result in some other direction.

Another way that might be considered would be to reduce maintenance expenses either by increasing the line covered by a maintainer, reducing supplies, or employing less expensive material and labor. The methods, on the face of them, do not appeal to many of us as entirely practical.

I believe you will all agree that true economy along any line is that economy which utilizes to the fullest extent the facilities at hand and produces the best results at the least expense. The real question for us to consider then is, how may we increase the service rendered by the telegraph department without materially increasing the cost of operation or maintenance and, if possible, decreasing this cost. Obviously any method adopted to improve service will require some initial outlay; but, like the expense incurred in reducing grades, improving power, and increasing the load, this outlay ought to be considered in its true relation to the work accomplished and the ultimate saving effected, not perhaps in actual expense in the telegraph department but in expense to the railroad company as compared with the receipts made possible by the improved service.

There have been means adopted in the past for increasing the efficiency of telegraph lines, such as duplexing, quadruplexing, employing machine-telegraph apparatus and later the typewriter telegraph; but, as you all know, the greatest innovation in the telegraph departments in recent years is the use of the telephone and, as the current used for this service is so different in quality and kind from that employed for telegraphic purposes, the bringing in of this device has changed and many times multiplied the favorable results obtained by the department.

The use of train dispatching telephone systems of various kinds is the latest development and, while the first cost of an up-to-date train dispatching line, complete, is considerable, I believe you will all agree that the expense is justified and that the improved service resulting more than pays a good rate of interest on the investment, not considering the saving in operating expenses made possible by closing telegraph offices which are but little used, installing telephones at sidings and thus making it possible for the dispatcher to receive information from, and issue orders direct to the trainmen.

When we get our dispatching circuit working on busy divisions, there is usually a demand for a like message circuit. When a road has the dispatcher's line and the message line in service, it is obvious that the wires may be used not only for these two very efficient services but for other purposes. A large part of all dispatching and message circuits now in operation have been simplexed for through telegraph work and a simplexed line can be duplexed and in some cases has been successfully quadruplexed. There is some question of the advisability of quadruplexing these simplexed lines, however, as they can be made to render more satisfactory service by compositing them and using the composite for through telephone service between division points.

In some cases plans are being made to extend this class of service in a little different way; instead of simplexing both dispatchers and message circuits, it is planned to phantom the two circuits and simplex the phantom and then duplex the simplex.

A case of wire economy which may be of interest to you, as it was to me, is on the Evansville & Terre Haute line of the Frisco system, where, with two No. 9 B. & S. copper wires and two No. 8 B. W. G. iron wires, the following services are obtained:

An ordinary telephone train dispatching circuit with 29 regular stations.

A metallic block signal telephone circuit with 27 stations.

A through simplex telegraph circuit over the dispatcher's lines.

A local simplex telegraph message circuit with 29 stations over the block telephone circuit.

It was found in actual practice that it would not be

* Paper read at the Boston Convention of the Association of Railway Telegraph Superintendents, June 26-30, slightly abridged.

Digitized by Google

practical to connect the thirty-six siding telephones on this division to the dispatcher's line. The business done from these telephones was of such a character and so great in volume that it would not be possible to issue all train orders if so much other business pertaining to occupied blocks, clear tracks, coal car orders and various other things were handled on the train wire. It was decided to connect these telephones to the block telephone circuits and have trainmen get their information from the block office; but another difficulty presented itself at this juncture: If the siding sets were not connected to the train wire, no train orders from the dispatcher's office could be given direct to trainmen at these points. To remove these objections the block circuits were so arranged that the block line (with whatever siding telephones might be connected to it) was connected through a repeating coil to the dispatcher's line; thus, while the dispatcher's line was relieved of the business of the siding sets, it was still possible when desired to connect them to the dispatcher's wire to receive important orders.

There are other features of interest on this division which show the extreme flexibility of the telephone system.

It might be worthy of note also to mention the fact that the through simplex telegraph circuit over the train wire is connected to a line running north to Danville and there through a repeater to the quad wire working into Chicago; also the local message telegraph circuit over the block wire works through to Danville over a local message wire.

Automatic drops are wired in the dispatcher's circuit so that if the bell rings at a station when the operator is out, the latter can readily determine this by glancing at his signal box when he returns. One telephone in such station performs all functions for both block and dispatcher's lines.

The only possible further service obtainable from these circuits would be a through grounded composite telephone from end to end of the dispatcher's line and in this case this might not be feasible owing to disturbances from surrounding wires. Now, doubtless some of us may be skeptical of the possibility of an ordinary lineman keeping a circuit of this kind in operation, but the reports are that the circuits are giving good satisfaction and the man who is maintaining them is the same lineman who has worked on their telegraph line for some time.

Now, in view of the extensive possibilities, increasing demands of traffic and the more or less increasing competition, true economy would appear to be for the telegraph departments to render all the service possible to both the passenger and freight traffic by all practicable means. Some of these means are utilizing the phantom telephone circuits or the message telephones for reservations, transfers, arranging to secure traffic, tracing lost shipments, and a hundred and one other things, which can obviously be done more expeditiously and economically by telephone and telegraph combined than by the telegraph alone. Considering all these facts is it not the truest economy to increase the service by increasing the utilization of present facilities, or even to increase the facilities rather than by cutting down the service to reduce the cost of operating the various departments?

Reunion of Old Timers and Military Telegraph Corps.

The thirtieth annual reunion of the Old Time Telegraphers' and Historical Association and the United States Military Telegraph Corps will be held at Atlantic City, N. J., September 5, 6 and 7. The headquarters will be at the Marlborough-Blenheim.

Following is the programme as officially announced:

Tuesday, September 5.—10:00 a. m.—Business meeting of the Old Time Telegraphers and Historical Association called to order by the retiring president, Mr. W. J. Lloyd, of Chicago. Address of welcome and response. Installation of the new President, Mr. W. B. Wilson of Philadelphia, Transaction of business, etc.—2:00 p. m.—Roller-chair trip. 7:30 p. m.—Business meeting of the United States Military Telegraph Corps. 8:30 p. m.—Concert and entertainment on Steel Pier.

Wednesday, September 6.—Morning—Ocean sailing. Afternoon—Trolley party to Ocean City. Evening—Concert and theatre entertainment on Million-Dollar Pier.

Thursday, September 7.—Morning—Ocean bathing. Afternoon—Go as you please. Evening—Banquet at the Hotel Shelburne.

The rates of the Marlborough-Blenheim are:

European Plan.—Single rooms without bath, one person, $2, $3, $4 per day; single rooms with bath, one person, $4, $5, $6; Double rooms without bath, two persons, $4, $5, $6; Double rooms with bath, two persons, $6, $7, $8.

American Plan.—Single rooms without bath, one person, $4, $5, $6 per day; single rooms with bath, one person, $6, $7, $8; double rooms without bath, two persons, $8, $9, $10; double rooms with bath two persons, $10, $11, $12.

Members desiring lower rates at other hotels can be accommodated by applying to the Chairman of the Hotel Committee.

The chairman of the various committees are: Mr. John Wintrup, reception committee, Old Time Telegraphers and Historical Association; Mr. Jesse W. Crouse, reception committee, United States Military Telegraph Corps; Mrs. Frank E. Maize, ladies reception committee; Mr. G. W. Deetz, Atlantic City, N. J., committee on hotels; Mr. John W. Reed, committee on badges; Mr. C. E. Bagley, committee on banquet.

Members who intend to be present at the reunion should notify the chairman of the hotel committee, Mr. G. W. Deetz, Western Union Telegraph Company, Atlantic City, N. J., as soon as possible, so that proper arrangements can be made.

It is possible that reduced railroad rates may be in effect from various sections in the country to Atlantic City during the time of the convention, and members who intend to be present at the meeting should make inquiry of their local railroad agent in regard thereto.

CHANGES OF ADDRESS.—In ordering a change of address the old as well as the new address must be given.
REMITTANCES to Telegraph and Telephone Age should be made invariably by draft on New York, postal or express money-order, and never by cash loosely enclosed in an envelope. By the latter method money is liable to be lost, and if so remitted is at the risk of the sender.

July 16, 1911.

Old Timers and Military Telegraph Corps Reunion.

We print elsewhere in this issue the official programme of the joint meeting in Atlantic City, September 6, 7 and 8 of the Old Time Telegraphers and Historical Association and the United States Military Telegraph Corps. These veterans find much enjoyment at their annual gatherings which afford them opportunity of meeting old acquaintances and making new ones. It is a pleasant break in the monotony of the humdrum life lead by most of the members, who as they grow older are inclined to break away from the strain and excitement of modern life and turn towards the things that bring calmness and peace into their lives.

The United States Military Telegraph Corps is composed of a brave lot of men who won the highest esteem of the great army commanders for their bravery and intelligent work in the field during the war. They, too, with their old-time telegraph brethren are deserving of the enjoyment and recreation they get at these joint meetings, and everyone will wish them all a good time at Atlantic City.

Telegraph Engineering.

The awakening that is taking place in the telegraph in this country in its engineering aspect is one of the most hopeful signs. The telegraph has long been regarded by many modern engineers as a sort of dead art, one that had exhausted all its possibilities, and had fallen into deep ruts of conservatism and lifelessness. But those who ever entertained such notions will be compelled to revise them and give the telegraph a more prominent place in modern industrial progress.

From an engineering standpoint the telegraph has not received the attention that its importance to the business world warrants, and its possibilities have not hitherto been investigated scientifically as have been the later applications of electricity. The attention of investigators has however been directed to the subject and there is every reason to believe that the telegraph will be established on a more scientific basis enabling the companies to obtain the best possible results from the least expenditure of material and energy.

The paper of Mr. F. F. Fowle read at the recent Boston convention of the Association of Railway Telegraph Superintendents, and printed elsewhere in this issue, is an important contribution on the subject of line conductor requirements for telegraph transmission and should be carefully studied by all interested in the physical development of the telegraph. Mr. Fowle is a trained engineer and has investigated his subject with great care. He has made a special study of the telegraph and points out the necessity for the application of scientific methods to its operation, as in all other modern industrial concerns. The fact that he is as practical as he is technical entitles his utterances to careful consideration.

Is There Stagnation in Promotion?

A correspondent writes: "The largest telegraphic system in the world has made a number of appointments lately. Upon what principal does this company select its men for promotion? When it selects men outside of its own employ, are we to infer that it has no men of its own good enough to promote? Are selections of this kind encouraging to the men, and again what is more discouraging than to have positions occupied year after year by the same person, keeping back all others behind them. The big railways, banks and other corporations have systems for regular promotion. This question is I think equally as important as that of superannuation."

Our correspondent brings up some important questions that are rather difficult to answer in a general way. The solution of the promotion problem has always been one of great concern to employing companies and it is a live question with them as to how to reward faithful and capable employes. The employes of a large industry—we use the term employes in its broadest sense—are naturally divided into two distinct classes, those who plan and supervise and those who perform the work. The official positions are few in number in comparison with those of the lower grades, and, in the case of a telegraph company, there are employes working at the desk who are capable of filling more important positions in the service. Many of these, especially those who live at a distance from headquarters, sometimes grow discouraged at the apparent slowness of reward for faithful services, and are inclined to think that the so-called demand for ability is largely a myth, and that what few vacancies in the higher grades are to be filled go to favored ones.

It may be accepted as a truth that the man who receives an appointment to a higher position receives it because he has rendered services which lead his superiors to believe that he is capable of filling the new duties. It is to some extent true that the

Digitized by Google

capable man at a distance is at a disadvantage, and that the capable man at headquarters is more likely to be the one selected other things being equal. This is not always the case, however. Many employes at points distant from headquarters get to the front in spite of so-called obstacles. Individual advancement unquestionably depends largely upon the man, whether he be at the home office or at a country office. If he has the real ability it will become known at headquarters.

Without any reflection, it may be pointed out that some men who think they are capable of filling higher positions and that they are being ignored, are really not as capable as they think themselves to be. They need to broaden their knowledge and thus better fit themselves for more important positions. An extraordinary knowledge of one subject is not so valuable to a man as a good knowledge of many subjects.

The telegraph companies know their men and when they have positions of importance and trust to fill they know where to find the men to fill them. It is very rare indeed that they are compelled to go outside of the ranks to find the ability. In making appointments to official positions it is the practice of the companies to select men from their own ranks, and for obvious reasons preserve their local identity as far as possible. It may be a surprise to many to know that at the present time, when the telegraph business is expanding so rapidly, that the companies do not always find it an easy task to find men to fill official positions particularly those of the higher grades. The local and general official conferences which the companies hold at more or less regular intervals are accomplishing much good in unifying the local and general interests, and incidentally the individual comes in for recognition on such occasions as necessities arise. Men are judged by what they do and not by what they say, and if a man performs his present duties well and is faithful to his trust, wherever he may be, the officials of the company will know of it eventually, and this man will be a "marked man" in one sense.

The companies cannot find outsiders to come in and conduct a business for which they are not trained; therefore the rank and file is and always will be the recruiting ground for candidates for higher positions.

The problem of making room for the rising generation is also a difficult one. Those who occupy the desirable positions seem to be of a long-lived race, and the younger generation naturally gets discouraged waiting for promotion. This condition largely gave rise to the pension idea which is now receiving so much attention. It is a good thing for the companies, too, to pension their older employes and thus bring the energy of youth and modern ideas into the business.

The whole question is a difficult one, viewed from any standpoint, and the telegraph companies themselves are just as much interested in its solution as are the individuals concerned and while there are no doubt many individuals who think they deserve a better fate than utter oblivion in some far-off place, it might be well for these to ask themselves if, after all, the trouble is not largely with themselves and not due to imaginary foes.

Telegraphy and Telephony in China.

During the present year depots will be established in China, for experimental purposes and also for the manufacture of telegraph and telephone instruments and materials and plans will be made for the erection of wireless-telegraph stations along the seacoast. Experiments will be made with automatic telephones in the city of Peking. The telephone systems at Tientsin and the Provinces of Kiangsu and Chekiang will be extended and enlarged.

In 1912 the northern and southern telegraph circuits of Shensi and Shansi Provinces will be extended, and officers will be sent abroad to investigate foreign-made electrical materials and compare them with materials manufactured in China. Telephone and electric-lighting systems in Hupeh Province will be extended, and telephone installations in Hunan and Shantung Provinces will be experimented with. In 1913 China will participate in the international electrical conference. Telegraph lines will be constructed in various provinces and experiments will be made with automatic telephones at Canton, Tientsin, and Shanghai; and with telephones in Shensi and Honan Provinces. Further depots for the experimental manufacture of submarine cables and all kinds of materials for electrical appliances will be established in 1914, and telephone systems will be tested in other provinces.

In 1915 many extensions to the telegraph and telephone systems will be made, the former including inner and outer Tibet, and in 1916 there will be great activity in all branches of electrical application.

Telegraph and Telephone Reports to the Interstate Commerce Commission.

According to Washington dispatches telegraph and telephone companies will not have to make reports to the Interstate Commerce Commission until further legislation by Congress is had on the subject. Congress thought it was putting these carriers on the same footing with railroads, but it so worded the law that the commission is uncertain what is meant. The law was specifically changed so that the commission has jurisdiction over telegraph rates in that it has decided it will exercise a power conferred. Until Congress makes the intent of the law clear the commission will not assume to construe the law that it has the power to order telegraph and telephone companies to make reports to it.

Child Labor in Pennsylvania.—The Philadelphia Child Labor Committee has addressed letters to the Western Union and Postal Telegraph-Cable Companies asking them to voluntarily establish an eighteen-year age limit for messenger boys working at night. The bill fixing the age limit for night work failed to pass the last legislature.

Possibilities of Railway Telephony.*

BY JOHN A. KICK.

The first train order sent by telegraph was refused by the engineer, as he declared it to be unsafe; yet trains have been dispatched for many years by this method. And now that we have the telephone supplanting the telegraph in train dispatching service, an occasional question is raised as to the safety of the telephone for the work. The transmission on up-to-date dispatch-circuits is so good that an ordinary conversational tone carries the entire length of the line and reaches the dispatcher so clearly and with such volume as to be understood without the straining effort which is experienced on the ordinary telegraph or telephone circuit.

By the discovery of the telephone's adaptability to dispatching, many of the most capable and experienced dispatchers were given a new lease of life in their positions. The telephone is not the nerve destroyer that the telegraph has been and many dispatchers who were on the verge of nervous collapse have grown young again.

For handling messages between way-stations, the telephone is very much superior to the telegraph, as the calling means absolutely no delay and the business can be transmitted with greater speed. One telephone message circuit equipped with selective signaling equipment and a first grade transmission system, will carry as much local way station business as two telegraph circuits in the same service. By this method of handling business at the main office, skilled telephone operators can be economically assigned to each message circuit, giving better service to the way stations than was possible where one operator had to take care of several Morse circuits.

On some short and unimportant branches one circuit has been used jointly for dispatching and message work. In some cases these branch lines have been cut through over a main line circuit by the use of a repeating coil or other means at the junction point. Branch lines may be normally connected to the main circuit or normally disconnected and can be switched selectively from the dispatcher's station or switched manually by the attendant at the junction point. The ringing from the dispatcher's station can be either selective or generator, as almost every circuit has some individual requirements. In arranging for operation it is necessary to go carefully into all the main branch line conditions before deciding on the best method to adopt.

For manual blocking both metallic and grounded telephone circuits are being used, either being superior to the telegraph blocking circuits. The circuits are arranged to be operated locally from station to station, but can be cut through by any station which is not a twenty-four hour blocking station.

In yard service the yardmaster keeps in touch with the entire yard by the use of a system of circuits connecting with the round house, machine shops and other departments over which he may call for or give instructions.

*From the *Telephone Engineer*.

Railway wrecking crews are called by the blowing of the machine shop whistles, by callers visiting the homes of the crew, by telephone service through the city exchanges, and last and best by the installation of a telephone system running from an independent switchboard direct to the home of each member of the crew, allowing the operator of this board to start the bells simultaneously and continuing to ring until each has answered, insuring the prompt starting of the wrecking outfit with full crew at all times.

Great transfer sheds, where forces of men transfer freight by trucking from one car to another, are being outfitted with telephone systems. One such system terminates in the general billing office, where a clerk is constantly on the line as a dispatcher, the foreman, freight checkers and others in charge at the platform and sheds are outfitted with breast plate transmitter and head band receiver on a cord and plug. As they go about the platforms they call into the line the clerk giving and receiving car numbers and assignments. For this service the circuit is brought to a jack at intervals of fifty to seventy-five feet, and the jacks so arranged and placed as to be accessible and at the same time protected from injury. The private branch exchange service in connection with railway operation is quite extensive on the larger systems and is a subject of such importance as to be worthy of considerable study and discussion.

Capable telephone engineers, installers and trouble men are securing good positions with the railways, and as the field is one in which many new conditions are met, the opportunities to show exceptional ability are many and the positions should be attractive.

Measuring Current Without Interrupting Circuit.

Mr. R. W. Paul, of South Newgate, England, has devised a method of measuring the current in an electrical conductor without breaking the circuit to insert an ammeter. The apparatus comprises a contact block with potential points and leads for connection to a millivoltmeter. The contact block is strapped by leather bands to the bare conductor. The millivoltmeter is so graduated that its reading multiplied by the cross section of the conductor in square inches gives the value of the current in amperes. In the case of metals other than copper the readings must be multiplied by the proportional conductivity. A simple circular slide rule is also provided. This is graduated in square inches and in sizes of stranded cable, and enables the value of the current to be read off very quickly.

This apparatus is not intended for use as a precision instrument, but readings can be made within a few per cent. In addition to its use for measuring current the apparatus provides a simple means for testing the conductivities of contacts, joints, fuses, etc.

Any book published on electrical subjects can be obtained of TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

The Integrity of the Telegrapher.*

BY JOHN E. LATHROP.

Not long ago, a matter was discussed by me and a mutual friend in which both of us were concerned; it was vitally important, and immediate communication was necessary with a third person who lived in Portland, Ore. I wrote a telegram, submitting it to my mutual friend; he demurred:

"I wouldn't trust that to the wires," he said. "It might be given away by some employe of the telegraph company."

"Have you done much business with the telegraph companies?" I asked.

"O, yes," he answered, "for many years."

"Have you ever known your private business to be betrayed by any employe of either of the companies?"

"Well come to think of it, I don't know as I have."

"I will venture the assertion," I continued, "that, were you to search your memory back to the time you placed your first telegram on the wires, you would recall not one single instance of such betrayal."

And, sure enough, he could not.

This caused me to think earnestly of the subject, and the more I thought the more I was impressed with the wonderful discovery we had made. These be days when the "muckraker" uncovers abuses in almost every realm of social activity, finds betrayal of public and private interests rampant, and every citizen, in his thoughtful moments, concedes that these abuses do exist, and that the average level of business probity needs to be raised. Is it not true that we watch our grocer, our tailor, our seamstress, the one for sand in our sugar, the other for cotton sewed into our clothing in place of the promised woollen, the other for faked work? And do we not need to watch almost everyone else down the several grades of society, until we reach bank presidents, railroad magnates and captains of industry?

Do we not in our inmost hearts realize that the dictum that "business is business" has made more or less sodden the processes of modern interchange of the products of men's efforts and their distribution to the folks who finally consume them?

Yet, throughout all of this apparent, if not real, degeneration of social business standards, in the twenty-five years I have used the telegraph wire, I have never known an instance of one of "the boys" betraying a trust reposed in him by patrons of that craft. It is an inspiring discovery! It is wonderful! We write telegrams containing the sacred secrets of our domestic lives, the delicate interchanges of thoughts between man and wife, all of the niceties of private intercourse, We write into them secrets vital to our business and professional success. We entrust to "the boys" that, which to reveal to others would, perhaps, spell embarrassment, even disaster.

Yet we "file" these telegrams confidently, knowing that we are safe. Have you fellows of the wires ever realized to what high level of honor you have achieved? Have you known that you wear constantly the insignia of a craft that the people know will keep the faith?

The more I have pondered these things the more I have been convinced that there is the greater genuineness in that splendid type of professional honor for the very reason that I never heard a man of the wires mention it. Certainly there is no room to apply that celebrated bit of philosophy wherein a certain one was suspected because she did too much protest her honor.

I never meet a telegraph operator since that day when we—my friend and I—had that conversation, that I do not feel like taking off my hat to him, as one of the fine products of our civilization that has maintained purest honor in his professional character and never has permitted his profession to be degraded. Possess, as he may, personal weaknesses, sin as he may against other laws that should be kept, yet the telegraph operator pursues his daily duties, keeping the faith of a nation, and investing his craft with a degree of confidence that would add weight to the repute of any mighty man of the ages.

Here's to the telegraph operator, an honest worker, who never thought to tell anyone that he was honest, but who nevertheless is honest to the core.

As I send this "copy" to Travis, I am handing to the Postal messenger boy, a lad I never saw before, a draft for $50 to be cashed. The lad will bring it back to me in an open roll of bills. I know he will—another wonderfully comforting assurance, and proving that Postal messenger boys, along with other messenger lads, have maintained that same fine sense of honor that marks the older men of the company. The other day I stood on the streets of New York and waited until a Postal messenger came back with the cash for another draft I was sending to the Postal to be cashed. Let's include the often abused messenger boy in our honor roll, for certainly he belongs there. So, here's to the messenger, too, whom every business man trusts as he would his own son.

* From the Postal Telegraph.

Lightning Statistics.—Four-tenths of one per cent. of the total number of buildings in Schleswig-Holstein, Germany, are annually struck by lightning. The number of buildings struck in the open country is nearly double that struck in the towns. The strokes were much more frequent and the damage was two and one-half times as great with buildings with thatched or wooden roofs as with slate or metal roofs. The greatest number of electric discharges was observed between 4 and 5 o'clock in the afternoon. All kinds of trees were struck, but certain kinds more frequently than others, depending upon the character of the bark and wood, which in some cases furnish a poorer conductor and thus afford greater protection than others. Poplars were most frequently struck. It was observed that strokes were two and one-half times more frequent in marshy than in dry sections, and that the frequency of strokes decreased with forest growth and increased with its removal.

Long Distance Wireless Telegraphy.*

In a recent lecture on radiotelegraphy before the Royal Institution, London, Mr. William Marconi gave an insight into the present state of the art of long-distance wireless telegraphy. Air condensers have been adopted at Clifden and Glace Bay and have effected economies in working and in energy losses. It was found to be neither economical nor efficient to attempt to obtain continuous waves. Much better results are obtained when groups of waves are emitted at regular intervals in such manner that their cumulative effect produces a clear musical note in the receiver, which is tuned not only to the periodicity of the electric waves transmitted, but also to their group frequency. Persistency of oscillations is obtained by employing an apparatus consisting of a metal disk having metal studs firmly fixed at regular intervals in its periphery and placed transversely to its plane. This disk is caused to rotate rapidly between two other disks by means of a motor or turbine and the side disks revolve in a plane at right angles to that of the middle disk. The studs are of such length as just to touch the side disks in passing. The frequency employed at Clifden is 45,000, and when a potential of 15,000 volts is used on the condenser, the spark-gap is practically short-circuited during the time in which one complete oscillation only is taking place, when the peripheral speed of the disk is about 600 ft. per second. The primary circuit, therefore, continues oscillating without material loss by resistance in the spark-gap.

An interesting feature of the Clifden plant is the regular employment of high-tension direct current for charging the condenser. Direct current at a potential capable of being raised to 20,000 volts is obtained by means of special direct-current generators. These machines charge a storage battery of 6,000 cells, all connected in series. Each cell has a rating of 40 ampere-hours. When the cells are used alone the working voltage varies from 11,000 volts to 12,000 volts, and when the generators and battery are employed together the potential might be raised to 15,000 volts by using the gassing voltage of the battery. The potential at which the condenser is charged reaches 18,000 volts, due to the presence of choke coils between the battery or generator and the condenser. Satisfactory insulation is obtained by dividing the battery into small sets of cells placed on separate stands suspended on insulators attached to girders fixed to the ceiling of the battery-room.

A curious result noticed in long-distance work is the effect produced by daylight on the propagation of electric waves over great distances. According to Professor Fleming, the effect should be more marked on long than on short waves, but Mr. Marconi has found the reverse to be true. In some transatlantic experiments in which waves about 8,000 meters long were used the energy received by day at the distant receiving station was usually greater than that obtained at night. Recent observations tend to show that the effects vary greatly with the direction in which transmission is taking place, the results obtained when transmitting in a northerly or southerly direction differing from those obtained when transmitting east or west. With wave-lengths of 7,000 meters and 5,000 meters the strength of the received wave remains steady, as a rule, during the day. Shortly after sunset at Clifden they become gradually weaker and about two hours later are weakest. They then begin to strengthen again and reach a very high maximum about the time of sunset at Glace Bay. They then gradually return to normal, but through the night remain very variable. Shortly before sunrise at Clifden they begin to strengthen and reach another high maximum shortly after sunrise at Clifden. The received energy then steadily decreases until it reaches a marked maximum a short time before sunrise at Glace Bay. After that the signals gradually come back to normal day strength.

Mr. Marconi is of the opinion that there is no foundation for the statement to the effect that the earth connection is detrimental to good tuning. A bad earth connection damps out the oscillations due to its resistance, and in that way makes tuning difficult, but no such effect is noticed when an efficient earth connection is employed. The earth wire may have a condenser or its equivalent in series with it.

*From the Electrical World.

A Young Operator.

Mr. Owen A. Conner, manager of the Boston office of the Western Union Telegraph Company has the distinction of being at the time he learned telegraphy, one of the youngest, if not the youngest, person who ever learned the art.

The *Journal of the Telegraph* many years ago printed a letter to the editor reciting the facts. The letter was written at Strasburg, Va. and was dated December 24, 1881. It was signed by "P" and in it the writer says:

"I notice in your issue of December 16, an item of news headed 'The Youngest Telegraph Operator.' I taught a young child in my office, in 1880, in his seventh year; and when he was eight years old he was fully qualified to take charge of a telegraph office. He received and sent messages with Edward Stewart, one of the champion senders. then in Washington City; it was on line No. 18, running from Staunton, Va. to Washington, D. C., this little operator, Master Owen Conner, worked. His father, John Conner, at that time was building manager on the S. V. R. R. between Waynesboro, Va., and Hagerstown, Md., but is now superinteding the building of lines west of Cumberland, Md., and Pittsburg, Pa. for the Western Union Telegraph Company."

Mr. Conner's early training made a first-class operator of him, and he has occupied positions of importance and trust. He was assistant manager of the Associated Press in New York for several years before entering the Western Union service.

The Late Charles Minot.

BY C. E. MCCLUER, NORFOLK, VA.

In view of the interest that you have aroused in connection with the proposed monument to commemorate the sending of the first telegraphic train order by the late Charles Minot, you may not perhaps be averse to the publication of a few reminiscences of him whose achievement it is thus proposed to honor.

With the foresight and enterprise that were among his chief characteristics, Mr. Minot, then the general manager of the New York and Erie Railway, early discerned the advantages that would accrue to the railway management by the adoption of the newly invented Morse telegraph as an adjunct thereto. Realizing with almost prophetic vision that with the natural increase in passenger and freight transportation, the single track of his road would soon become overburdened and handicapped by the difficulties of moving with dispatch and regularity the large number of train units that would be required, he rightly reasoned that the telegraph would largely solve the problem of handling trains successfully. He therefore, when the telegraph was in the first or second year of its existence, induced his company to authorize the construction of a telegraph line along its right of way, for the exclusive use of the railway management.

When I, a lad of fifteen years, in 1852 entered the service of J. W. Norton, a pioneer in the supply and manufacture of electrical material and apparatus, the railway telegraph line was in process of construction. I found Mr. Norton furnishing material and apparatus for the construction of the line and the equipment of the offices, under contract, and Mr. Minot displaying so much interest in the progress of the enterprise that he would trust no one but himself to give orders for the shipment of material.

It is difficult for one familiar with the electrical industry in this, the sixth decade in the history of the telegraph, to realize that in those early days the Norton establishment was the only electrical manufacturing concern in existence in New York City, if not in the entire country, and that his force of workmen and subordinates comprised only a half dozen journeymen, brass finishers and perhaps an equal number of raw apprentices working in a little shop in Center street near the New York "Bastile," the "Tombs," equipped with no labor-saving machinery or contrivances save a few foot-power lathes and hand drill-presses.

I was Mr. Norton's sole assistant in the storeroom at 177 Broadway, and was required to perform the manifold duties of bookkeeper, cashier, salesman and errand and office boy. On account of Mr. Norton's frequent and protracted absences from the store it often developed upon me to wait on Mr. Minot and show him new material and apparatus, and take his orders. I thus struck up with him quite an intimate acquaintance, and was fortunate in securing his friendship and favor.

On the occasion of one of his visits, Mr. Minot learning of my ambition to become a telegraph operator, volunteered the promise to give me a job on his railway line as soon as I was competent to take charge of an office. Redoubling my efforts to master the art of telegraphy, I practiced assiduously and became so enthused with the idea that I was quite proficient in the use of the Morse alphabet almost before I was aware of it. In fact, having no one to coach me or instruct me in the formation of the dash and dot characters, I did not realize the progress I was making until chance or accident brought an operator into the store one day while I was exhibiting and explaining the operation of the telegraph to a party of visitors anxious to learn something about the time and distance annihilating device. Listening to my dissertation for a while, he finally interposed a suggestion that the party should divide and transmit messages to and fro between the exhibition instruments at each end of the long storeroom. This was done and much interest evinced and amusement enjoyed by the visitors. I officiated at one end of the wire and my friend at the other. After the visitors left us my friend gave expression to the opinion that I was already a good operator and abundantly able to take a position on a commercial wire, adding that I was fully as expert in reading the characters on the register tape, and transmitting the dots and dashes on the wire, as the majority of the fellows in the business.

I had been practicing industriously for five or six weeks, utilizing all my spare time at the key or reading the dead messages on the old register paper sent to us as packing material with instruments returned for repairs, and using my thumb and index finger in the formation of the telegraphic characters while trudging the streets, and the names on the signs over the stores as the subject matter, but I really did not know until on that occasion that I was anything of an operator. My friend however insisted that I hold Mr. Minot up to his promise, which I did on the occasion of his very next visit, with the result that I was soon installed in the railway office at Piermont as assistant to Mr. Chapin, the recently appointed superintendent of the Eastern division.

Thus began my telegraphic career. And now after many vicissitudes and adventures during over fifty years telegraphic and telephonic experience, I find myself back at the "key" where I began. But not the raw youth that I was when Mr. Minot became my benefactor and started me on my electrical career, but in a ripe and rugged old age, though still capable of putting in a good day's work at the key.

I cannot recall whether Mr. Minot's pioneer telegraphic train order episode occurred before or after my connection with the road. But it was a year or two after my début as a telegrapher, and after I had drifted as far West as Owego, before I had an experience which was the immediate occasion of the formal introduction of the telegraphic train order system.

I sincerely hope that a fitting monument to Mr. Minot's genius will be speedily erected and inaugurated.

Line Conductor Requirements for Telegraph Transmission.*

BY FRANK F. FOWLE, CONSULTING ELECTRICAL ENGINEER, CHICAGO.

Telegraph transmission from an engineering standpoint seems to have attracted comparatively few investigators, and when the author undertook a complete investigation of the subject more than a year ago it was found that the existing literature was extremely meager. On the side of practice the telegraph companies have adhered quite closely to rather ancient standards, although there have been persistent efforts to bring about improvements in equipment and radical changes in transmission methods. Very lately there have been a number of notable improvements in equipment, but practically all of the telegraph business of the country is still handled by the Morse system, with manual operation.

Dealing from an engineering standpoint with transmission problems as they now arise, the Morse system becomes practically the sole consideration. The problem of greatest fundamental importance is how to secure commercially efficient transmission at the lowest cost; and where long distances are involved, the largest single factor is the selection of the line conductor. But overall or total efficiency has here two components, or factors —the efficiency of the line and the efficiency of the equipment. Naturally each affects the other, and a proper solution in any case implies that the chosen combination of line and equipment is the most economical one.

It is very well understood in the case of telephone transmission that the size of the line conductor must be increased as the length of the line increases, which was illustrated in a paper read before this Association, by the author, in 1905. The same is true in the case of telegraph transmission, although no rule could be found which expressed the size or properties of the conductor in terms of the length of the line. Perhaps an exception ought to be made in the case of lines wholly in cable, for there the well known KR law has been employed empirically to find the required properties of the conductor. But certainly in the case of lines made up in great part, or wholly, of open wire, there has been no well established rule or proceedure, except to copy existing practice.

Long experience with Morse transmission, by the various telegraph companies, has gradually evolved the present standard practices, reached in most cases by cut-and-try methods. Today there are two types of line conductors used very extensively, No. 9 B. & S. gauge, hard-drawn copper, weighing 209 pounds per mile and No. 8 Birmingham gauge, B. B. galvanized iron, weiging about 385 pounds per mile. These conductors are standard, the former for the lines of greatest length and severest service, the latter for the lines of short and medium length and quite generally for way or local wires. It has become rather the custom to accept these standards without much question as to how closely they fit the needs of the case, or whether different conductors could not be substituted with a marked saving in cost.

The specific problem placed before the author in the investigation before mentioned was a comparison of various kinds of wire for telegraph service, and a determination of their relative costs. Finding no established theory or proceedure as a guide, it was necessary to develop the theoretical side of the subject rather elaborately. This work led to results somewhat beyond the intended scope of the investigation and pointed the way to numerous improvements in telegraph practice, which will be described in their turn.

Morse transmission as employed so extensively in this country makes use of the familiar closed circuit system, and operates with direct-current sources of e.m.f., or energy. In the transmission of impulses, by the opening and closing of a key, there are two distinctive intervals or time-periods to consider. The first interval is that during which the current is changing from one steady value to another, which commences at the instant of opening or closing, and is termed the transient state. The second commences when the steady current value has been established or the transient state ceases, and continues until the next movement of the key. During the transient state the current obeys very complicated laws and in general it takes the form of a high-frequency oscillation. But the transient state is of very brief duration, except in long cables. During the second or steady state the current obeys Ohm's law in every case.

In general there are two factors of practical moment in judging the commercial quality of transmission. These factors are not always separable, but for present purposes we may regard them as so. The first is the speed of transmission, as affected by the duration of the transient state; if the transient state occupies a comparatively long interval, as in high-capacity cables of great length, the signals must be sent at very low speed in order to preserve their individuality and insure their arrival at the far terminus. On lines of open wire not exceeding 500 or 600 miles in length, the transient state is exceedingly brief, and the speed of signalling is ordinarily far above the maximum ability of an expert manual operator.

The second factor is the strength of the signals. Whenever the line is very highly insulated the final strength of the received signal will equal the strength of the outgoing signal, and both are determined by Ohm's law. Referring again to the case of long cables, it is obvious that an outgoing signal may be cut so short that it will never arrive with full strength at the distant end. But open wires have entirely different properties and the very brief nature of the transient state insures that the shortest signal, with manual operation, will penetrate to the far terminal with full strength, when the insulation is high. In every case, however,

*Paper read before the Convention of the Association of Railway Telegraph Superintendents, Boston, Mass., June 26-30.

Digitized by Google

it is evident that inadequate strength is a factor which positively limits transmission, no matter whether the speed is high or low.

Cable transmission, referring to underground and aerial construction, is limited, as we all know, by considerations of speed. There the insulation is ordinarily several hundred megohms per mile, and there is no perceptible loss of current by leakage at any time. Open-wire lines, on the other hand, are never very highly insulated under any conditions, and the degree of insulation fluctuates between wide extremes with changes of weather. Hence both speed and strength of signals must be considered in the latter case, and the KR law is entirely inapplicable for these and other reasons.

Experience with open-wire lines shows us, in a very conclusive way, that where the current strengths are adequate and the relays are properly adjusted, the limits of distance or line length are fixed by the maximum leakage (or minimum insulation resistance) and not by the inability to signal with requisite commercial speed. It is well known, for illustration, that signals can be transmitted to greater distances when the insulation is high, or in fair weather, than when it is low, or during a prolonged or heavy rainfall. American experience confirms this almost universally.

Proceeding from these facts, the theoretical investigation of transmission was confined to a study of the second or steady state, before mentioned, which obeys Ohm's law. The statement of this law in its elementary form is exceedingly simple, but the application of it to the case of a long line with uniformly distributed resistance and leakage requires the use of considerable mathematics, although not of a difficult order.

Mr. Fowle gives the results of the mathematical analysis at considerable length, and then takes up the subject of relative costs of different kinds of line wire.

Under the leakage theory of transmission here developed, the paper continues, the proper basis for comparing different kinds of wire is one of equal conductivity or resistance. This basis, however, only applies to the purely electrical requirements. Equally important is the requirement of tensile strength, including the allied mechanical properties of modulus of elasticity, elastic limit and temperature coefficient of expansion.

Copper and iron have been standard materials for many years, although the so-called iron now obtained is usually mild steel. In the last five years there has appeared on the market a new type of wire known as copper-clad steel, with whose properties some of you are familiar. Fundamentally this wire consists of a steel core with a copper shell or jacket welded thereto, thus avoiding the faults of the early bi-metallic wire. Comparing it size for size with copper and iron, it has more resistance than copper, but less than iron; that is, it is intermediate between the two. But mechanically it is superior to either. Now first of all we need to know how these materials compare in cost for equal resistance.

The proper cost to consider in this case is annual cost, or the sum of the annual interest charges, taxes, depreciation and maintenance. The first cost and the annual cost have been computed for several sizes of each kind of wire, including in the first cost only the wire, insulators, tie-wires, pins, joints and labor of installation—but no pole line cost. Interest and taxes have been taken collectively as 7 per cent. annually, and maintenance as uniformly $1.00 per wire-mile. The total depreciation has been found by deducting the salvage or scrap value from the first cost and adding the cost of taking down the wire when it is worn out; the whole sum has then been divided by the number of years of life, to find the annual depreciation.

The base price used for copper wire is 13.5 cents, with a salvage value of 11.25 cents at the smelter; a small freight allowance has been included both ways.

The base price of copper-clad, current on the same recent date, was 13.25 cents less 3 per cent. for cash in 15 days and 7 per cent. for quantities exceeding 15,000 lbs. The salvage price was 3.5 cents based on actual inquiry of second-hand metal dealers. A freight allowance was made both ways.

The current price of B.B. galvanized iron, which is cheaper for simple conductivity than E.B.B. iron or steel, ranged from 3.25 cents to 4.00 cents, according to size. No scrap value was allowed.

The assumed life for copper is 50 years, based on what the wire ought to do under reasonable conditions. Large wires will last longer, of course, than small ones, owing to the greater strength. As a matter of fact, copper ought to last indefinitely under favorable conditions, because it suffers no corrosion. Its life in service is usually terminated by such factors as heavy sleet storms, the necessity of taking down and moving whole pole lines, gradual stretching and periodical removal of slack, and sometimes by annealing—caused by very heavy foreign currents or exposure to fires. It is also very sensitive to rough handling and often fractures under stress at a small nick or furrow in the surface.

The assumed life for copper-clad is also 50 years, arrived at after a careful study of the properties of the wire and its manufacture, also taking into account the experiences up to this time of numerous users of it. The life of copper-clad ought to be greater, for some reasons, than the life of copper. It is more hardy mechanically and need not be so carefully handled. The tensile strength resides to a great extent in the steel core, which is a large advantage, making it less likely to fracture from nicks or scratches. Compared size for size with copper, it will fail under sleet and wind loads much less frequently and stretch less. It has a much higher elastic limit of strength than copper and consequently relieves itself of stresses due to overloaded spans to a greater degree; this comes about through the increased sag which results from elastic stretching of the conductor. In many cases where copper would stretch permanently, copper-clad will not. Copper is by no means an ideal conductor mechanically,—in fact we tolerate its defects in that direc-

Digitized by Google

tion for the sake of the needed conductivity. On the other hand copper-clad is much superior mechanically and its welded copper jacket presents the same resistance to external corrosion as solid copper. The only other place where corrosion can attack the wire is at exposed ends; and experiments made to determine this, under conditions tending greatly to accelerate it, show an absence of corrosive action at the weld and a tendency to corrode at the center of the core, but not penetrating to a serious extent. This is quite the opposite result from corrosive tests on the early bimetallic, non-welded wire.

The assumed life of iron, of the B. B. grade, double galvanized, is 20 years. This figure is rather high, but has been made so purposely, in order to be conservative in comparing iron with copper-clad. A life of 15 years is probably more representative of average conditions.

The comparison of first cost and annual charges, per mile, is given in Table I. Attention is called to the fact that the gauge used in the table is B. & S. for copper and copper-clad and B. W. G. for iron.

TABLE I.

	First Cost			Annual Charges		
Size.	Copper.	Copper-Clad.	Iron.	Copper.	Copper-Clad.	Iron.
No. 6	$65.66	$55.49	$27.61	$6.05	$5.76	$4.36
No. 7	53.83	45.74	23.48	5.17	4.94	3.87
No. 8	44.44	38.04	21.11	4.47	4.29	3.58
No. 9	37.24	32.11	18.64	3.94	3.79	3.29
No. 10	31.33	27.25	17.14	3.50	3.38	3.11
No. 11	26.82	23.51	15.38	3.17	3.07	2.90
No. 12	22.94	20.44	14.38	2.88	2.81	2.78
No. 13	20.21	18.16	13.27	2.68	2.62	2.64
No. 14	17.79	16.16	12.39	2.50	2.45	2.54

The table shows that size for size copper-clad is cheaper than copper from 9 per cent. to 15 per cent. in first cost. But the comparison of cost on a basis of equal transmission efficiency must be made on a basis of equal resistance and in terms of annual

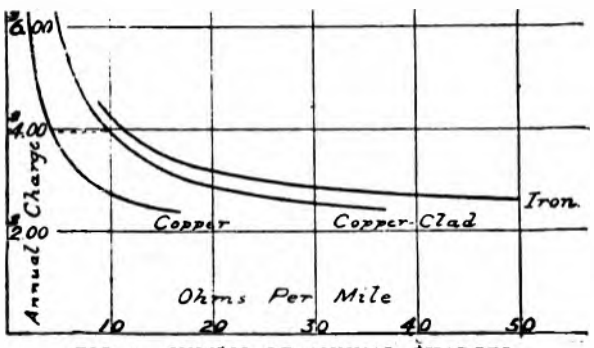

FIG. 1.—CURVES OF ANNUAL CHARGES.

charges. This comparison appears in Fig. 1, where the annual charges are plotted in terms of ohms per mile.

These curves show that in respect to resistance, alone, copper is the cheapest material of all and copper-clad steel second, while iron is the most expensive. It may be emphasized that the showing for iron is the best that can be made assuming it to be new; but when corrosion commences the resistance will increase and then it becomes still more expensive. On a conservative basis, in fact, some increase in resistance should be allowed for at the outset, so that the desired transmission limit will not fall short of requirements before the wire reaches the end of its usefulness or life.

This comparison takes no account, however, of tensile strength. The choice evidently lies between copper and copper-clad, in the first place, on the score of economy. It only remains to take up the question of strength. Obviously copper would be the chosen material for any requirement if it possessed the strength to stand up mechanically. But we know from experience that sizes smaller than No. 9 B. & S. lack strength and even this size fails occasionally in severe sleet storms, and stretches frequently.

The operative limit of such a wire is 437 miles and hence copper is the proper material for lines of this length or greater. But No. 9 B. & S. copper-clad, which is only a trifle less expensive on the score of annual charges, has considerably higher resistance and in consequence an operative limit of only 290 miles. Therefore No. 9 B. & S. copper would be used for all lines between 290 and 437 miles in length. But copper-clad is more economical for all lines less than 290 miles in length,—simplex transmission being always assumed.

This establishes the field for copper-clad in telegraph service, as comprising the lines in general less than 300 miles in length, based on conditions as we find them at present. Where automatic repeater stations can be installed, or now exist, the economical range can be extended very greatly.

* * * * * *

It is convenient to have the operative limits of various sizes of wire of each kind. These are given in Table II, where the sizes of copper and copper-clad refer to the B. & S. gauge and iron to the Birmingham gauge.

TABLE II.

	Operative Distance, in Miles		
Size.	Copper, (B. & S.)	Copper-Clad, (B. & S.)	Iron, (B. W. G.)
No. 6	585	397	306
No. 7	535	358	274
No. 8	485	322	253
No. 9	437	290	229
No. 10	395	261	209
No. 11	357	235	187
No. 12	321	211	172
No. 13	289	188	150
No. 14	260	169	...

While the economical field for copper-clad, under existing conditions of insulation, comprises the lines of 300 miles or less, its field can be extended to 600 miles if the insulation is raised to one megohm per mile. This means, of course, the adoption of better insulators. While this implies an increase in the cost over the present glass insulator, there is every reason to believe that it will be a final economy of no small importance.

METHODS OF IMPROVING TRANSMISSION.

The best conditions for securing the desired transmission most economically have already been covered in part. These will now be recapitulated and several new features added.

(1). SOURCE OF E. M. F.—Divide the total e. m. f. into two equal parts and place one at each terminal. The lumping of the whole e. m. f. at one terminal is the least efficient arrangement possible. Use power generators, motor generators, or dynamotors instead of batteries wherever feasible and economical. When batteries are necessary, operate but one line per battery except where the lines are short and the margin ample.

(2). TERMINAL RESISTANCE.—Keep the total terminal resistance at a minimum. Use resistance lamps with iron filaments instead of carbon. Also keep the terminal resistances as nearly equal as possible. When a generator or some equivalent source of e. m. f. is employed, never use one lamp tap for more than one line, unless the lines are short and the margin ample.

(3). CIRCUIT BREAKERS.—An automatic circuit breaker, of special design, is recommended as a substitute for the lamp resistance. This will avoid the resistance in large part and provide fully as much safety. The circuit breaker can be arranged, if desired to cut in the protective lamp resistance instead of opening the line entirely.

(4). RELAY WINDINGS.—The most efficient insulating material known for magnet windings with wires of small size, is enamel. It occupies less space than a covering of single silk. Consequently the necessary number of turns can be secured with less total resistance. The neutral relay in a quad set is most in need of improvement, comparatively, and here enamel will be of special advantage. One manufacturer who makes both polar and neutral relays, uses enamel with the former and silk with the latter; the practice ought to be reversed—but better still, enamel should be used entirely.

(5). ARTIFICIAL LINES.—The artificial lines employed in duplex and quad equipments, with their lumped resistance, capacity and leakage are exceedingly crude imitations of a real line with the same properties uniformly distributed. Improvement in such equipment, along the pattern of the artificial line described in this paper, will help in extending the range of transmission. The plan may also be carried so far as to provide the artificial line with the electrical equivalent of the distant terminal, which is likely to be of most benefit when the line insulation is at its maximum. The design of such a line offers no serious difficulties, but it will be somewhat more expensive.

(6). RELAY DESIGN.—This subject has been treated at some length in the author's American Institute paper, but the point to be emphasized is the fact that the use of enlarged pole-pieces, with a magnetic circuit of a certain class, increases the pull on the armature. Putting it differently, the pull now obtained in a 150-ohm relay can be produced in a relay of the new type with only a small fraction of that amount of resistance.

(7). IMPROVED INSULATORS.—The advantages of better insulation have already been demonstrated. The means of securing it will be discussed briefly. There is already some experimental evidence, although not extensive, that glazed porcelain makes an insulator superior to glass. But one of the prominent faults of the standard glass insulator is its form, coupled with the method of mounting it. Dependence for insulation is placed primarily on maintaining a dry interior under the outer petticoat, but this fails of realization on account of spattering of water (during rainfall) into the petticoat from the top surface of the cross-arm beneath the insulator.

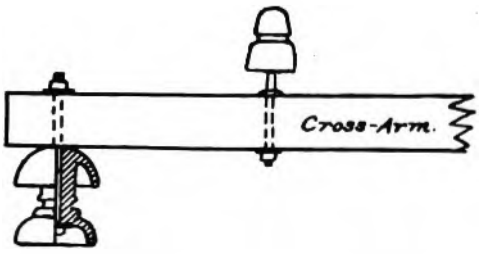

FIG. 2.—INSULATOR BENEATH CROSS ARM.

A superior method of overcoming this appears to be the use of an insulator placed beneath the cross-arm and held by a rigid pin, after the plan shown in Fig. 2. This removes the objection of

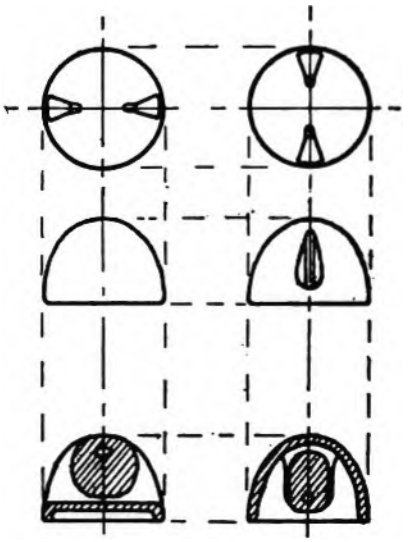

FIG. 3.—NEW TYPE OF STRAIN INSULATOR.

spattering from the arm and is mechanically just as rigid as the present standard; a large under flange is employed to prevent the tie-wire from slipping down.

A more radical proposal is the use of a flexible

Digitized by Google

suspension with a strain insulator of the type shown in Fig. 3. This plan is suitable for straight portions of pole line and owing to its flexible character will tend to reduce wire-stripping in a heavy sleet storm. The insulator itself is suspended from the cross-arm by a loop of wire, and the line wire is supported in turn from the insulator by means of a tie-wire. Attention is called to the form of tie, which is wrapped around the line from each side toward the center, in opposite directions, with the ends pig-tailed at the center; it is practically impossible for it to fail except by fracture. These plans for improving the insulation, and others, are discussed in the other paper before the American Institute of Electrical Engineers, more fully than space permits here.

Vibratory Sending Machines.

BY JOHN A. ESSLINGER, OF WASHINGTON, D. C.

Before the recent discussion arose as to the detrimental effect of vibratory sending machines upon multiplex circuits and knowing of the practical impossibility of passing machine-made signals through repeaters when the signals were speeded up to a point beyond the carrying capacity of the circuit, I realized that if a single set would not carry the rapid dots and dashes a duplex pole-changer certainly could not do so, let alone a quadruplex. The sending machine can be set for a speed of 40 or 45 words per minute by proper adjustment of the weights, one at the spring point and the other at the end of the vibrating device, and it will transmit as well, if not better, than the average hand sending.

The inability of the standard instruments to respond to high speed impulses is due to the fact that an electrical impulse requires time to reach its maximum value. We provide a means in a telegraph line to meet the impulse as nearly half-way as possible, but then the armature of the relay must travel its course without assistance and it is only by reducing the distance between the contact points that higher speeds are possible.

If a telephone receiver is connected between a sending machine and a relay it will be found that the discharge vibrations of the diaphragm receiver and the front contact of the relay armature will occur simultaneously when the speed exceeds the operating capacity of the relay.

On a single line measuring 2,000 ohms resistance with several 150-ohm relays in circuit, each exercising a retarding influence, it is evident that the charges and discharges of the line will reduce the working margin to such a degree that the most distant relay gets only a small amount of current variation.

Sometimes an increase in current strength will aid in carrying the rapid impulses over the line, but when this is done we develop other troubles. Frequently an operator at one end of a single line complains that there is no margin or that the signals come weak, while at the other end the reverse condition exists.

A test was recently made on a New York—Washington circuit which developed a condition similar to this. There was an electrical pressure at New York of 80 volts with an average of .100 amperes, while at Washington there was a pressure of 110 volts and an average of .021 amperes. Such discrepancies could be easily remedied if the line and equipment permitted one office to decrease and the other increase its current output to meet such conditions as these at a moment's notice.

The following table shows why such conditions are difficult to overcome. The table was prepared from average readings taken over a period of two weeks in good weather on two wires, one leased from the Western Union and the other from the Postal. The values given are in milliamperes.

VARIATION IN CURRENT AT WASHINGTON ON OPENING AND CLOSING.

	Line A		Line B	
	Min.	Max.	Min.	Max.
Circuit closed	54	62	23	37
Washington sending	0	58	0	33
Baltimore sending	9	56	4	31
Philadelphia sending	17	54	11	28
Newark sending	21	52	16	26
New York sending	25	51	18	25

Taking a variation of only seven milliamperes in ordinary hand speed, it is not to be wondered at that speeds two to three times as fast made with a vibrator would reduce the margin of current to barely enough to start the relay armature. The variation of twenty-five milliamperes required an adjustment to compensate for the current strength and the impulse must be proportionate. It can be stated that the cause for such a condition is due to a partial ground at some point on the line, usually by moisture effecting an escape. In damp weather when the escape is general or unevenly distributed, the speed of the vibrator is an important factor. If it is too high the dots will not go through, but if the vibrator is held down with sufficient weight, it will form dots superior to hand-made dots, first because there is more uniformity in the contact up to the seventh or eighth dot than any but the most accurate hand can execute; second, because the cleavage is more clearly defined by allowing a greater opening than is usually given the points of a key owing to the inability of the hand to work well on too wide a swing, and third, because the machine produces an initial physical reaction which a key does not, thereby relieving the nerve-trying delayed "sender's interval" when the line is responsive.

Mr. E. W. Collins, district superintendent, Postal Telegraph-Cable Company, Cleveland, Ohio, writes: "I have been renewing my subscription to the TELEGRAPH AND TELEPHONE AGE for so many years that it has become a habit—one of my good habits—and the publication has grown better from year to year, just as you and I have grown older."

Subscribe for Telegraph and Telephone Age. It is the leading paper of its class in America.

QUESTIONS TO BE ANSWERED.

[The success which has attended our plan of publishing in each issue a list of questions covering the subjects considered in Jones' Diagrams, has encouraged us to maintain the work through other books. Students of telegraphy throughout the country are finding these questions of great assistance in their studies of the general principles underlying the operation of the apparatus with which they come in daily contact. Many consider this the best plan which has yet been devised for a systematic study of the technical side of the telegraph. Having completely covered Mr. Jones' book we are now covering "The Quadruplex," by Maver and Davis, and will bring out, in a like manner, all the facts that every telegrapher should know about duplex and quadruplex telegraphy as found in this book.]

CHAPTER VI.

Referring to Fig. 25, which is of the polar duplex, what are condensers *C* and *C'* adjusted for?

Under what circumstances does the line static discharge manifest itself?

What is the effect upon the line discharge of the condenser discharge?

What should be the value of the resistances *H* and *H'*?

How are the electro-magnets of the polar relays wound?

Under what conditions will no magnetism be produced in the home relay?

What will be the effect of placing battery *B'* in the circuit with its negative pole to the line?

What is the result of placing the positive current to the line?

Study carefully the effect of opening the key of the home pole changer while the negative pole of battery *B'* is to the line.

Under this condition is there any current on the line?

What becomes of the current from the two batteries when they are placed in opposition to each other?

If a battery with a strength of 50 units at one end of the line is placed with its positive pole to the line and a similar battery at the other end with its positive pole to the line also, how much current will there be on the line and what will be its sign?

Reverse the polarity of one of the batteries so that its negative pole will be presented to the line, what will be the value of the current on the line and what will be its sign?

If a battery of 100 units positive is connected to line at one end and another battery of 50 units negative at the other end, what is the resultant current upon the line?

Is the magnetic polarity of the home differential polar relay affected by changes of polarity of the home battery?

Deterioration of Ebonite.

Ebonite, or, as it is commonly called, hard rubber, is affected by light and the sulphuric acid thus freed decomposes the material. This effect is shown by discoloration.

The deterioration of ebonite has been investigated by the English national Physical Laboratory and the results are published in the annual report of that institution. Samples of many qualities of ebonite were placed under a sheet of glass to protect them from dust, and exposed for many months to a north light. A portion of each was covered with a brass disk which protected some of the surface of the material from the action of the light, and the production of acid could be roughly gauged by the gradual discoloration of the brass. It was found that a yellow glass acted as a great protection and that a blue glass had but little effect in delaying the production of free acid. The effect can be greatly reduced by covering the apparatus with a glass whose surface is coated with a layer of gelatine containing a yellow or red dye, but this has not been found a complete protection. The only entirely satisfactory method, where high insulation is required, is to cover all ebonite by wood or opaque glass or other material, leaving holes for the handles required for manipulating the necessary switches and for making the electrical connections. A third arrangement which has been successfully adopted is to depend on amberite (an artificial amber made from amber waste) for insulation.

The insulation may be restored by thorough washing, and it has generally been found that the rate of production of acid diminishes and that the trouble lessens as time goes on. In certain qualities of ebonite this is accompanied by a change in the color of the surface, which gradually becomes a greenish gray, and which, as far as observation has gone, is electrically as good and more permanent than the polished black new surface. It is quite possible that a satisfactory material might be produced by aging the surfaces through exposure to a strong light and by frequent washings.

Seasoning Wood by Electricity.

The following item from a British technical paper concerns a new process of seasoning wood by electricity in France.

A large tank is filled with a solution containing 10 per cent. of borax and 5 per cent. of resin, with a trace of carbonate of soda. In the bottom of the tank is a lead plate which is electrically connected to the positive pole of the dynamo. The timber to be treated is stacked on this plate, and when the tank has been filled another plate is superimposed and connected to the negative pole of a dynamo. When the current is switched on it passes through the stack of wood between the two plates, and in its passage it is said to drive out the sap in the timber and deposit borax and resin in its place, completely filling up all pores and interstices. When the process is completed the timber is removed and dried, after which it is ready for use. It is claimed that the timber submitted to this treatment, no matter how green it may be, becomes completely seasoned.

High Speed Automatic Perforators, or Perforator Receivers.*

BY WILLIAM MAVER, JR.

The recent introduction of a night and day "letter" service in this country has virtually necessitated a further resort to the use of automatic telegraphy for the more efficient and possibly more economical handling of the increased business which this service has developed, and should the public appreciation of this service continue to grow no doubt there will be need for a still greater extension of automatic telegraphy in this country.

Thus far the Wheatstone automatic system is the one at present most favored and perhaps this system will continue to be the one most generally employed in connection with certain adjuncts in the shape of key-board perforators for the rapid preparation of messages for transmission, and various forms of so-called receiver perforators which automatically perforate a paper strip with holes representing the dots and dashes of signals arriving at repeating stations (or, if desired, at terminal stations), thus saving the labor and expense of manual reception (or transcription) and subsequent manual re-transmission at such repeating stations.

The nature of the business to which the night and day letter service caters, may be classed as consisting of telegrams, the immediate delivery of which is not vitally important, and therefore may be deferred.. This class of business is largely commercial and social and consequently it concerns the regular telegraph companies more than the railway telegraph departments, but it may be that a brief description of automatic perforating and transmitting devices now being introduced in this country and of others already in use in various other parts of the world for the handling of business of the general nature of night and day letter service, press news, etc., may suggest a possible use of such apparatus in the railway telegraph service. But be that as it may it is believed by the writer that the apparatus in question is itself of sufficient merit and importance to attract more than passing interest on the part of those engaged in the practice of telegraphy in any of its departments, more especially indeed when it is stated that the utility of automatic perforators is not by any means limited to the transmission of press news or to deferred telegrams, as is manifested by the fact that they are also employed in regular telegraph service abroad and are finding an increasing and valuable use in connection with the operation of long Wheatstone duplex circuits of some international telegraph and cable companies.

It is, of course, generally known that messages are prepared for transmission by the Wheatstone automatic system by perforating holes in a paper tape, which holes represent dots and dashes of the Morse or other codes. This tape is in turn passed through a transmitter which, by a system of rapidly oscillating vertical rods, operates a pole changer which results in the transmission of dots and dashes (corresponding to those representing the letters and words of the prepared message) over a line at a speed of about 600 words per minute, on short lines, and at about 100 words per minute in each direction on long duplex circuits, such, for instance, as the New York-Chicago duplex circuits. The messages thus transmitted are usually received on a paper strip in dots and dashes by an ink recorder operated by a main line polar relay.

In the preparation of these messages for transmission, two general methods are employed, namely, the mallet puncher and a keyboard perforator. By the mallet method, three punching keys, or discs, are struck separately by the operator with a rubber tipped mallet; No. 1 key for a dot, No. 2 key for a space, and No. 3 for a dash. The dot key punches two large holes opposite in the paper tape and one center hole; the dash key punches two large holes diagonally across the tape and two center holes; the space key simply perforates a small center hole and advances the paper. This method of preparing the messages, although obviously cumbersome, fatiguing and compaartively slow (about 20 words per minute) is still in extensive use in connection with this system of automatic telegraphy. But as previously intimated, keyboard perforators are also now employed, by means of which the characters of any letter of the Morse alphabet are perforated on the tape by the depression of the key representing that letter. The Buckingham keyboard perforator in this country, and the Gell keyboard perforator in Europe and other foreign countries are the ones most generally employed. The Gell perforator has many points of simplicity, and is in use in numerous instances in the British Government telegraph and newspaper telegraph departments in Great Britain, for the preparation of press dispatches for transmission by the Wheatstone system. By keyboard perforators messages are frequently punched at the rate of 60 words per minute; and in Europe it is common practice to feed the tape thus perforated directly from the keyboard perforator to the Wheatstone transmitter, the keyboard operator supervising the entire operation.

As already noted it has long been the custom to receive the dots and dashes transmitted by the Wheatstone automatic system in Morse characters in ink on a paper strip, from which strip the message is transmitted, or typewritten, by a copyist. In repeater stations, however, the message is frequently relayed by an operator who reads the message directly from the tape, thereby avoiding manual transcription of the message in the repeating station. But to avoid even the necessity for this manual repetition of a message is one object in using automatic receiver perforators,

* Paper read at the Boston Convention of the Association of Railway Telegraph Superintendents, June 26-30. Abridged.

Digitized by Google

or re-perforators. It is a comparatively simple matter to punch short and long holes in one line in a paper strip, as the dots and dashes are slowly received on a Morse relay, but the matter of re-transmitting the message at high speeds from these perforations presents some difficulties. Besides it involves the installation of apparatus different from the existing Wheatstone, thereby adding to the diversity of apparatus in an office, which is sometimes considered more or less objectionable. The Stevens-Wheatstone perforator is a high speed automatic re-perforator of this type. The perforated paper tape is used for re-transmission.

The d'Humy high speed receiver perforator is in use in the Postal Telegraph-Cable Company's service. Unlike the perforations made by the Wheatstone perforator and the Gell re-perforator, which for a dot, dash or space are always of the same length on the paper strip, the holes in the d'Humy perforated strip vary as to distance between them according to the speed of transmission and the rate at which the paper tape is drawn along. Also the perforations for a dot or dash depend on the interval between the marking current and the next spacing current. This receiver perforator is capable of perforating the paper strip at a maximum rate of about 90 words per minute. The maximum speed of re-transmission from this tape is about 50 words per minute.

The Creed high speed automatic re-perforator is due to Mr. F. G. Creed of London, and has come into use within the past few years. By its means the signals received by a main line Wheatstone relay are automatically reproduced in facsimile of the original Wheatstone perforated strip, at a speed of approximately 200 words per minute, which strip can be re-transmitted by a Wheatstone transmitter at any desired rate of speed, within the capacity of the circuit.

Under the control of line signals from a Wheatstone transmitter this automatic perforator is capable of punching the paper tape at a maximum speed of 200 words per minute. Its normal speed is from 125 to 150 words per minute. An important advantage of this tape is that being an exact reproduction of the Wheatstone perforated slip it may be utilized for re-transmission through a Wheatstone transmitter at any speed of which the original is capable. It is worthy of note also that this perforator will reproduce on the paper strip a fac-simile of the Buckingham-Barclay printer alphabet at a higher rate of speed than the same characters can be converted into Roman letters by the printer. Hence, if desired, this strip could be utilized to transmit local traffic into the printer on a local circuit and the through traffic could be re-transmitted from the perforated strip, without additional manual preparation or manual transmission, by the Wheatstone transmitter or other printer circuits.

It is well known that the position method of signaling is employed in submarine cable telegraphy, that is, dots are recorded on one side of a zero line and dashes on the other side of a paper strip by the siphon recorder, and dots and dashes, arbitrarily so called, are of equal length. Then signals are now very generally transmitted over the cable circuits by a machine akin to the ordinary Wheatstone transmitter, but the arrangement of the perforations on the paper strip are different from those of the regular Wheatstone strip, the dot perforations being on one side of the strip, the dashes on the other. The same inventor, Mr. Creed, has devised a machine termed a perforator translator, by which the ordinary Wheatstone strip received by a perforator receiver from the land lines is a cable telegraph station, is translated into a perforated strip for transmission by the cable automatic transmitter. The translator consists of a system of rods which pass through the holes of the Wheatstone strip, or are restrained from this movement by the uncut paper, the mechanism so acting as to produce holes corresponding to dots on one side of the paper and to dashes on the other side. The power for operating the punches in this machine is supplied by a crank pin on a disc operated by an electric motor, in a measure somewhat analogous to that of the Stevens-Wheatstone perforator.

It will be obvious on consideration, as Mr. Creed has mentioned to the writer, that successful practical devices of this kind may find numerous applications. For example, on very long circuits, such as those between New York and San Francisco, which, with ordinary automatic or direct point repeaters might not, under the most favorable conditions, operate at much over manual transmission speed. By placing automatic perforators at the repeating stations a speed equal to that obtainable on the longest single section of the circuit may be attained, which speed might readily be more than double that of hand transmission. The time thus saved on the shorter sections when still higher speeds are of course attainable could be utilized for the transmission of local business. Obviously also in the event of wire trouble on one section of such circuits the business could be automatically perforated at the terminals of that section and transmitted when the wire trouble is removed or, in the meantime, could be re-transmitted by alternative routes, without additional manual preparation.

Another advantage in this relation is that, and referring especially to the Creed device, new and perfect perforated slips are supplied at each repeating station since a distortion of signals that would act unfavorably on a direct point repeater is automatically corrected by this receiver perforator, which by means of its correcting rods has, according to the inventor, a margin for correction of distorted signals of about 50 per cent.

In fact, the Creed receiver perforator has already been utilized in the manner indicated on the 4,000 mile circuit of the Indo-European Company from London to Karachi, India. This cir-

Digitized by Google

cuit has been operated by Wheatstone automatic for several years and has required ten repeating stations, namely at Lowerstoft, Emden, Berlin, Warsaw, Rouno, Odessa, (Russia), Kertch, Sukhum, Kaleh, Tiflis and Tauris. More recently a Creed re-perforator has been installed at Odessa, this breaking up the circuit into two parts with a resulting increase in speed and reliability. Also the Eastern Telegraph Cable Company, operating between Great Britain, Egypt, India, Capetown and Sydney (Australia), is now introducing twenty-six of these perforators on its lines, and these perforators are now in use in Great Britain and other parts of Europe. Hence, from the foregoing, it is evident that automatic perforator receivers have passed the experimental stage, and there appears to be little question that the near future will see an increased employment of such devices, either in their present or in an improved or modified form.

DISCUSSION.

Mr. A. G. Saylor, general superintendent of the Western Union Telegraph Company, New York, being invited to make some remarks, said:

"Permit me to say that I have listened with great interest to the paper just read by Mr. Maver, who so ably and fairly presents the various features of automatic telegraphy. It occurred to me that possibly some remarks in connection therewith may be of interest. I wish to confine myself to the operation of the automatic service, as at present employed in the Eastern Division of the Western Union Company. I will not attempt to bear upon the technical features of the automatic transmission of messages, and it is understood that nothing stated shall be construed as comparing one automatic with another, in either efficiency or economy in operation. All automatics in actual practice have their advantages and disadvantages. At the present time we have in our service, three classifications of automatics, first, the Wheatstone, second, automatic cable transmitter and recorder, third, the automatic printing system.

"I believe it will be conceded that the Wheatstone, in its field, is unexcelled, and is particularly adapted to long land circuits. It is in operation in the Eastern Division between New York and Chicago, and between the Central Cable Office and North Sydney cable station, Nova Scotia. The tape as received is pasted upon the regular receiving blanks, which are then distributed throughout the operating departments, the same as any other messages. With very limited experience, all Morse operators can readily read the Wheatstone tape as recorded in the Morse alphabet. Therefore, the necessity for transcribing this tape is entirely eliminated. The Morse characters as they appear on the Wheatstone tape may not always be uniform, but any imperfection is as readily interpreted as the imperfections of a Morse sending operator. On the ordinary Wheatstone circuit, the average speed approximates 100 words per minute.

"In connection with handling cable traffic, the technical features of the system have been very clearly and ably stated by Mr. Maver. In reference to the automatic perforation of the receiving tape, preparatory to transmission this may have at the present time passed the experimental stage. I believe that it will be obvious in operating practice to concede its value, particularly at relay points, for the reason that it obviates the necessity for manual perforation and any delay incident thereto, but in this connection it should be explained that at cable relay stations, there are two methods employed in transmitting from the receiving tape. On our cable between New York and Penzance, England, via Bay Roberts, N. F., the speed of the two sections is uniform, and the capacity is somewhat over two hundred letters per minute. At Bay Roberts the receiving operator perforates directly from the slip as it is received, and the tape is fed into the transmitter of the second section of the cable. At our Canso, N. S., cable station, the operator transmits the messages from the tape over the second section of the cable as received, the automatic transmission being employed only at times when the load of the traffic justifies it. At some of the intermediate cable stations, there has been employed for many years, an automatic relay or repeater, which is equivalent to the automatic repeater of the land line circuits.

"There is no perceptible difference in operating expense between the automatic relay or repeater and the present method employed in the combination of manual relaying at intermediate cable stations. Automatic repeaters at intermediate stations, do not to any great extent decrease the operating expense. It is doubtful whether the automatic repeaters reduce to any extent the operating cost, for the reason that at the cable stations where they are employed, the operating force has not to any extent been reduced, as it is necessary to maintain the force to meet emergencies when they may arise. The vested capital in the cables is so great that the operating expense is not a great factor compared with the benefit to be derived by operating them to their full capacities as and when required, and to render the public a prompt and reliable cable service.

"Mr. Maver has made reference to the siphon recorder. This recorder at rest makes a straight or neutral line or demarkation on the tape. Upon the reversal of the current by the transmitter, the dots are recorded on one side of the neutral line and the dashes on the other. As you know, the Continental alphabet is used. On many of our cables, the number of dots of a letter is judged by the duration of the period that the siphon records, before it is attracted to the neutral line. The definitions on the tape of various cable circuits materially differ one from another depending upon the length and capacity of the cable. At many stations cable operators of experience can read the tape on the short section but it is with difficulty that they can readily read the definitions of the siphon recorder on the longer sections. At the terminii of the cables, we employ two experienced cable operators on the receiving side of each. The cables as you know are worked duplex. As the tape comes from under the siphon, a cable operator transmits in Continental alphabet

Digitized by Google

to a receiving operator at his side who writes the cablegram on a typewriter.

"The automatic printing system depends entirely upon electrical and mechanical perfection in its operation. The printer now employed has recently been improved so that its efficiency is fairly well maintained during weather-bound conditions. By reason of its sustained efficiency, we now average on the various circuits, approximately 90 messages per hour The messages are first perforated by use of keyboard perforators and fed through an automatic transmitter, and at the receiving station are received automatically in typewritten form, on regular receiving blanks, ready for distribution and delivery. I am not prepared to say that there is any economy in operating expense in the employment of automatic transmission as compared with the regular transmission of business by Morse, but there is no question that there is great economy in plant costs in connection with both the Wheatstone automatic and our printer system."

Mr. W. J. Camp, of Montreal, described the methods in vogue in transmitting business to and over the British Pacific Cable. The Canadian Pacific land lines connecting with this cable between Montreal and Bamfield is operated daily, the distance being over 3,100 miles. The Wheatstone system is used on this circuit entirely whether there is one message or one hundred. Perforated tape is used for transmission on the cable between Bamfield, B. C., and Fanning Island, which he understood is the longest cable in the world. He did not favor vibratory transmitting machines. They do not carry through repeaters so well as hand transmission.

Morse Electric Club Outing.

The summer outing of the Morse Electric Club was held at Donnelly's Boulevard Hotel, College Point, L. I., N. Y., July 8, over one hundred members being present. The weather was delightful and a very enjoyable time was had by all. The party was conveyed to College Point from New York in the afternoon by the Western Union Company's cable steamer, *Robert C. Clowry*, which was placed at the disposal of the club for the purpose. During the afternoon athletic contests were held on the grounds adjoining the hotel.

The baseball game between the Operators and the Executive Department clerks was won by the former, the score being 5 to 3.

The 100 yard dash, handicap, for members only, was won by Mr. J. A. Dierks, Mr. W. A. Schudt, being second, and Mr. L. D. Beall, third.

The second race, 100 yard dash, handicap, was won by Mr. W. C. Merly, Mr. J. A. Berry, second, and Mr. J. A. Sweeney, third.

The third race, 100 yard dash, free for all, (non-members) was won by Mr. J. C. Coffey with Mr. L. V. Murphy second and Mr. H. Ayres, third.

The fat man's handicap of 60 yards was the next event and caused considerable merriment. It was won by Mr. J. F. Nathan, with Mr. J. F. McGuire, second, and Mr. M. J. Hayden, third.

The free for all race, 100 yard handicap, was won by Mr. A. C. Gibbs, Mr. W. Finn taking the second prize and Mr. A. Finn the third.

The starter in these events was Mr. J. F. Nathan and the judges were Messrs. B. H. Reynolds, and L. Dresdner.

An excellent dinner was served and during the meal entertainment was furnished by a guitar and mandolin quartette and songs by Mr. W. Logan, all joining in the chorus. At the conclusion of the dinner there was a drawing for prizes which included canes, umbrellas, fountain pens and roasts of beef.

The party returned to the city by boat and the sail on the sound and river in the moonlight was delightful. During the games in the afternoon the party was interested in the flight of an aeroplane high above the ball field.

The Turner Monument Fund.

At the recent meeting in New York of the Railway Signal Association favorable mention was made of the Turner Monument project and it is probable that this branch of the railway service will support the movement.

Mrs. Geo. S. Minot, of Brookline, Mass., a niece of the late Charles Minot, has subscribed $25 toward the Turner Monument Fund. Mrs. Minot was a guest of honor at the recent convention in Boston of the Association of Railway Telegraph Superintendents and prior to the session of the first day she received in the hotel parlors those members of the Fund committee that were present.

Mr. E. P. Griffith, chairman, and the other members of the Fund Committee, are to be congratulated on the able manner in which they have handled the work of securing the necessary funds and the generous response of Mrs. E. H. Harriman, of Arden, N. Y., has given special gratification. The committee in co-operation with Mrs. Harriman's representative and Sculptor Charles Keck of New York, are actively engaged on the final preparations for the monument.

Any one who desires to contribute toward the fund has yet an opportunity to do so. No one having any pride in the object of this project should fail to subscribe. The list is still open, and contributions should be forwarded to the treasurer, Mr. J. B. Taltavall, TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

Contributions received up to date are as follows: Previously acknowledged, $1,616.25; Mrs. Geo. C. Minot, Brookline, Mass., $25.00. Total, $1,641.25.

Indictment of Wire Corporation Officials.—The grand jury, United States Circuit Court, New York, on June 29 returned nine indictments against officers of the American Steel and Wire Company and thirty-five other corporations and partnerships in the steel and wire industry which the Federal authorities have been investigating. These indictments are found under the Sherman Act, and charge a combination and conspiracy in restraint of interstate and foreign commerce.

Report of Committee on High Tension Wire Crossings.*

The Committee on High Tension Wire Crossings submitted specifications for overhead crossings of electric light and power lines, the same being the joint report of similar committees of the National Electric Light Association, the American Railway Engineering and Maintenance of Way Association, the American Electric Railway Association, the American Institute of Electrical Engineers and the Association of Railway Telegraph Superintendents.

Following are the specifications recommended for adoption:

GENERAL REQUIREMENTS.

1. SCOPE: These specifications shall apply to overhead electric light and power line crossings (except trolley contact wires) over railroad right-of-way, tracks, or lines of wires; and, further, these specifications shall apply to overhead electric light and power wires of over 5000 volts constant potential, crossing or constructed over telephone, telegraph or other similar lines.

2. LOCATION: The poles, or towers, supporting the crossing span preferably shall be outside the Railroad Company's right-of-way.

3. Unusually long crossing spans shall be avoided wherever practicable.

4. The poles, or towers, shall be located as far as practicable from inflammable material or structures.

5. The poles, or towers, supporting the crossing span, and the adjoining span on each side, preferably shall be in a straight line.

6. The wires, or cables, shall cross over telegraph, telephone, and similar wires wherever practicable.

7. Cradles, or overhead bridges, shall not be used.

8. CLEARANCE: The side clearance shall not be less than twelve feet (12'0") from the nearest rail of main-line track, nor less than six feet (6'0") from the nearest rail of sidings. At loading sidings sufficient space shall be left for a driveway.

9. The clear headroom shall be not less than thirty feet (30'0") above the top of the rail under the most unfavorable conditions of temperature and loading. For constant potential, direct current circuits, not exceeding 750 volts, when paralleled by trolley contact wires, the clear headroom need not exceed twenty-five feet (25'0").

10. The clearance of alternating-current circuits above any existing wires, under the most unfavorable condition of temperature and loading, shall be not less than eight feet (8'0") wherever possible. For constant potential, direct-current circuits, not exceeding 750 volts, the minimum clearance above telegraph, telephone and similar wires, may be two feet (2'0"), with insulated wires and four feet (4'0") with bare wires.

11. The separation of conductors carrying alternating current, supported by pin insulators, for spans not exceeding 150 feet shall be not less than:

Line Voltage.	Separation.
Not exceeding 6,600 volts	14½ in.
Exceeding 6,600 but not exceeding 14,000	24 in.
Exceeding 14,000 but not exceeding 27,000	30 in.
Exceeding 27,000 but not exceeding 35,000	36 in.
Exceeding 35,000 but not exceeding 47,000	45 in.
Exceeding 47,000 but not exceeding 70,000	60 in.

For spans exceeding 150 feet, the pin spacing should be increased, depending upon the length of the span and the sag of the conductors.

NOTE.—This requirement does not apply to wires of the same phase or polarity between which there is no difference of potential.

With constant potential, direct-current circuits, not exceeding 750 volts, the minimum spacing shall be ten inches (0'10").

12. When supported by insulators of the disc or suspension type, the crossing span and the next adjoining spans shall be dead ended at the poles, or towers supporting the crossing spans, so that at these poles, or towers, the insulators shall be used as strain insulators.

13. The clearance in any direction between the conductors nearest the pole, or tower, and the pole, or tower, shall be not less than:

Line Voltage.	Clearances.
Not exceeding 14,000 volts	9 in.
Exceeding 14,000 but not exceeding 27,000	15 in.
Exceeding 27,000 but not exceeding 35,000	18 in.
Exceeding 35,000 but not exceeding 47,000	21 in.
Exceeding 47,000 but not exceeding 70,000	24 in.

14. CONDUCTORS: The normal mechanical tension in the conductors generally shall be the same in the crossing span and in the adjoining span on each side, and the difference in length of the crossing and adjoining spans generally shall be not more than 50% of the length of the crossing span.

15. The conductors shall not be spliced in the crossing span nor in the adjoining span on either side.

16. The method of supporting the conductors at the poles, or towers, shall be such as to hold the wires, under maximum loading, to the supporting structures, in case of shattered insulators, or wires broken or burned at an insulator, without allowing an amount of slip which would materially reduce the clearance specified in paragraphs No. 9 and No. 10.

17. GUYS: Wooden poles supporting the crossing span shall be side-guyed in both directions, if practicable, and be head-guyed away from the crossing span. The next adjoining poles shall be head-guyed in both directions. Braces may be used instead of guys.

18. Strain insulators shall be used in guys from wooden poles carrying any power wire of less than 6,600 volts. Strain insulators shall not be used in guying steel structures, nor required on wooden poles carrying wires all of which are 6,600 volts or more.

19. CLEARING: The space around the poles, or towers, shall be kept free from inflammable material, underbrush and grass.

20. SIGNS: In the case of railroad crossings,

*Presented at the Boston Convention of the Association of Railway Telegraph Superintendents, June 26-30.

Digitized by Google

if required by the railroad company, warning signs of an approved design shall be placed on all poles and towers located on the railroad company's right-of-way.

21. GROUNDING: For voltages over 5,000 volts, wooden crossarms, if used, shall be provided with a grounded metallic plate on top of the arm, which shall be not less than one-eighth inch (⅛") in thickness and which shall have a sectional area and conductivity not less than that of the line conductor. Metal pins shall be electrically connected to this ground. Metal poles and metal arms on wooden poles shall be grounded.

22. The electrical conductivity of the ground conductor shall be adjusted to the short-circuit current capacity of the system and shall be not less than that of a No. 4 B. & S. gauge copper wire.

23. TEMPERATURE: In the computation of stresses and clearances, and in erection, provision shall be made for a variation in temperature from 20° F. to 120° F. A suitable modification in the temperature requirements shall be made for regions in which the above limits would not fairly represent the extreme range of temperature.

24. INSPECTION: If required by contract, all material and workmanship shall be subject to the inspection of the company crossed; provided that reasonable notice of the intention to make shop inspection shall be given by such company. Defective material shall be rejected and shall be removed and replaced with suitable material.

25. On the completion of the work, all false work, plant and rubbish, incident to the construction, shall be removed promptly and the site left unobstructed and clean.

26. DRAWINGS: If required by contract, complete sets of general and detail drawings shall be furnished for approval, before any construction is commenced.

LOADS.

27 The conductors shall be considered as uniformly loaded throughout their length, with a load equal to the resultant of the dead load plus the weight of a layer of ice one-half inch (½") in thickness, and a wind pressure of 8.0 lbs. per square foot on the ice-covered diameter, at a temperature of 0° F.

28. The weight of ice shall be assumed as 57 lbs. per cu. ft. (0.033 lbs. per cu. in.).

29. Insulators, pins and conductor attachments shall be designed to withstand, with the designated factor of safety, the tension in the conductors under the maximum loading.

30. The poles, or towers, shall be designed to withstand with the designated factor of safety, the combined stresses from their own weight, the wind pressure on the pole, or tower, and the above wire loading on the crossing span and the next adjoining span on each side. The wind pressure on the poles, or towers, shall be assumed at 13 lbs. per square ft. on the projected area of solid or closed structures, and on one and one-half (1½) times the projected area of latticed structures.

New Book.

"Wireless Telegraph Construction for Amateurs." By A. P. Morgan. The intense general interest in wireless telegraphy is evidenced by the number of books being published on the subject, and as a rule they are excellent expositions of the art. This new book is all that could be desired for the beginner especially, and, indeed, for the technical and practical wireless telegrapher as well.

The subject is very thoroughly covered, and the language is so clear that the reading and study of the work is a course of instruction in itself. An idea of the scope of the book may be obtained from the chapter headings as follows: Introductory, Apparatus, Aerials and Earth Connections, Induction Coils, Interrupters, Transformers, Oscillation Condensers and Leyden Jars, Spark Gaps or Oscillators, Transmitting Helixes, Keys, Aerial Switches and Anchor Gaps, Hot Wire Ammeter, Oscillation Detectors, Tuning Coils and Transformers, Receiving Condensers, Telephone Receivers and Headbands, Operation.

The book is well illustrated with views of aerials and circuits of all kinds and of the instruments used in wireless telegraphy. The author's purpose is to give practical information for those who may wish to build for private or experimental use a set of wireless instruments which are more than toys but yet not so expensive as the commercial apparatus, and he has used the English language to good advantage in the attainment of his purpose. The book is well gotten up and shows pains and experience in its execution. The price is $1.50 per copy, and copies can be had from Telegraph and Telephone Age, 253 Broadway, New York.

Electric Interlocking Machines.—The General Railway Signal Company, Rochester, N. Y., has issued a supplement to its catalogue of its model 2 electric interlocking machine. The supplement deals with special parts for the control of the model 2-A dynamic indication semi-automatic signals as shown in catalogue, section 8, part 3, issued by this company.

LETTERS FROM OUR AGENTS.

NEW YORK, WESTERN UNION.

Miss Jane F. Powell of this office has been transferred to the United States Hotel office at Saratoga, N. Y., as manager and Mrs. S. Kirschbaum has been transferred as manager of the Fort Griswold Hotel, New London, Conn.

Mr. James Young has been appointed acting manager of the 65 Gold Street office, vice Mr. L. E. Westrope who is now acting manager of the 91 Wall Street office.

Mr. V. M. Sozzi has been appointed manager of the newly-opened office in the Heidelberg Tower Building, Forty-second Street and Broadway, New York.

Mr. J. Reynolds has been appointed manager of the office at 32 Desbrosses Street, vice Mr. V. M. Sozzi.

Mr. M. Silverstein has been appointed manager

Digitized by Google

of the office at 1771 Broadway, vice Mr. A. K. Ainley, who has left the service.

Mr. Joseph Silberstein has been appointed manager of the office at 449 West Thirteenth Street, vice H. Weidler transferred to the commercial superintendent's office, New York.

PHILADELPHIA, WESTERN UNION.

Miss Nellie Hayes, chief clerk to general traffic manager, F. R. Webb, was married to Mr. M. A. Maloney on June 26. Miss Hayes was so well thought of that the employes presented her with a solid silver service. After her honeymoon she will reside in West Philadelphia.

Miss Bessie Sacks is on her usual summer vacation of three months in Maine, and Mrs. Katie Quinn, wife of the assistant night chief, is subbing for her.

The company is putting in large ventilators which it is hoped will afford some relief to the heated conditions in this office.

J. J. Richards, chief machinist of the Barclay printer, has resigned and his place has been taken by H. H. Swartz, who recently returned from South America.

Traffic chiefs from Baltimore and Washington, together with those from Philadelphia, held a conference here a few days, for the purpose of exchanging ideas and experiences. After the business session they were entertained on the roof garden of the Continental Hotel.

Mrs. Frank E. Maize, has been selected as chairwoman of the entertainment committee of the Old Timers at Atlantic City, N. J., September 5, 6, and 7, and she promises the ladies a good time.

ST. LOUIS AMERICAN TELEPHONE & TELEGRAPH.

Mr. Charles Gadberry, late chief test board man at Denver, Col., has been transferred to the test room at St. Louis.

Mr. Octavus M. Eaves has been transferred from the test room at St. Louis to Denver, as test board man.

Mr. J. C. Fallinger, late operator in the division office at St. Louis, has gone to Kansas City, Mo., to fill a similar position there, the division office having been removed to Kansas City.

Mr. M. M. O'Neill, of the test room has the sympathy of his many friends in the loss of his little daughter, who died on June 27.

Mr. A. H. Fredericks, recently of the Postal Company, is substituting in the test room during the summer vacations.

Mr. Sidney J. Ewald, late district plant chief at St. Louis, Mo., on the eve of his departure for his new post as district plant chief at Indianapolis, Ind., was the recipient of a handsome alligator traveling bag and toilet outfit from the St. Louis employes, as a token of their respect and esteem.

MOBILE, ALA., WESTERN UNION.

Mr. S. Boone has been appointed chief operator of this office succeeding Mr. J. D. Hester who retains the position of wire chief.

DALLAS TEX. WESTERN UNION.

Mr. H. P. Bond of this office has been promoted to be night chief operator, vice R. E. De Lay, resigned.

On his departure, Mr. De Lay was presented with a gold watch and fob by the operating force, as a token of their esteem.

Mr. J. B. Dillon, assistant wire chief days, succeeds Mr. Bond as wire chief.

The great telegraphic song hit,
"SEND ME A NIGHT LETTER, DEARIE."
Good, catchy music; beautiful title design magnificently printed in colors. Title contains night letter. Sung all over New York, 17c. by mail. All popular music sent by mail.
B. L. BRANNAN,
195 B'way, N. Y.

FOR SALE—A Bunnell galvanometer, complete in leather case, with resistance coils and connections for Wheatstone bridge measurements. Must be disposed of immediately to close an estate. Cost over $100.00. Will sell for $35.00. Address "Galvanometer," care Telegraph and Telephone Age, New York.

The Telegraphers' Mutual Benefit Association, 195 Broadway, New York, combines fraternalism with sound business principles; it offers to the telegraph and telephone employe an absolutely safe form of protection, at a cost within the reach of all and lower than can be found elsewhere. Membership only open to employes in commercial or railroad telegraph or telephone service, and it is manifestly to the interest of those who are eligible and wish to secure life insurance within their means, to secure without delay a certificate for $1,000 or $500, or both, at rates based on present age.

TRANSMITTING MACHINES

I am placing on the market improved YETMAN TRANSMITTING TYPEWRITERS, and KEYBOARD TRANSMITTERS without typewriting features. Am prepared to exchange, repair or rebuild all old machines. Write for catalogues and particulars to

James Uncles, NORTH ADAMS Massachusetts

Rubber Telegraph Key Knobs.

No operator who has had to use a hard key knob continuously should fail to possess one of these flexible rubber key caps, which fits snugly over the hard rubber key knob, forming an air cushion. They render the touch smooth and the manipulation of the key much easier. Price, fifteen cents.

J. B. Taltavall, TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

Every one engaged in telegraphy and telephony should be a constant reader of TELEGRAPH AND TELEPHONE AGE. It gives the latest news in both these fields. Subscribe now. Subscription price, $2.00 per year.

SOME POINTS ON ELECTRICITY.

BY WILLIS H. JONES.

A NON-SPARKING POLECHANGER.

One of the factors which tend to lower the effectiveness of polechangers, is the tendency to sparking at the contact points when the current is broken, which is particularly pronounced in the walking-beam pattern.

This defect has thus far always been minimized by means of condensers employed for that purpose. It is obvious, therefore, that a polechanger which requires no extra condensers is a move in the direction of economy to say the least.

The accompanying diagram shows the connections of a new polechanger recently invented by Mr. Stephen D. Field, which seemingly is nonsparking up to 200 volts pressure. It is also a continuity-preserving contact-point device; contains no extra resistances and occupies less space than the old walking-beam apparatus.

Referring to the illustration, transmitter *I* is actuated by the local battery *L* which, when the key is closed, energizes the "kick-off" coil *I* as well as magnet *T*. Armature *A* is made of steel and receives a residual charge from magnet *T*, becoming selfpolarized, the charge changing with the change in direction of the current from the local battery.

When the key opens the "kick-off" coil *I* acts on the selfpolarized armature and sends it back with a force equal to that by which it was attracted. Spring *S* possesses sufficient tension to preserve the back contact unbroken in the event of jarring of the table when the local circuit is open. This form of spring is "atonic," that is to say, possesses no time of vibration and acts instantly, while at the same time the contacts thus made are singularly free from rebound.

The neutral coils *B*, *C*, are automatically cut out of circuit, while their discharge being in the same

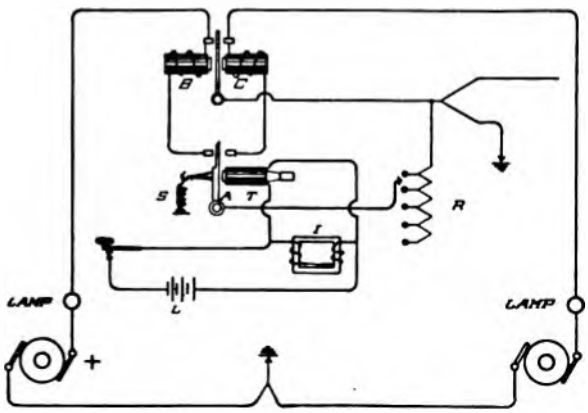

DIAGRAM OF NON-SPARKING POLE CHANGER.

direction as the current by which they are energized compensates for the momentary disturbance in the circuit during the period the spacing lever is occupied passing from one contact point to the other.

Mr. Field states that one of these polechangers has been in practical operation on a 325-volt circuit for more than two months and so far shows no tendency to spark.

While on the subject of polechangers it may be in order to say that that instrument, together with the carelessness with which it is frequently handled, has always been one of the weakest factors in the dynamo quadruplex system, owing to the break which occurs during reversals. The latter defect can be minimized by means of condensers and close adjustment of the contact points but unfortunately close adjustment of points is not always permissible on long circuits employing high voltages. Even when conditions favor a close adjustment it has been almost impossible to maintain the same because operators and others insist upon giving the lever wider play in order to hear the transmitted signals. This practice reduces the working margin of the neutral side of the quadruplex circuit.

Digitized by Google

The true aim, therefore, is to devise a polechanger which will possess continuity-preserving contact-points and be free of tendency to spark. The apparatus herewith illustrated was devised with the aim of meeting both of these requirements.

Let us hope that another advance has been made in this line of progress. If we do finally succeed in obtaining a reasonably perfect instrument half the "troubles" now experienced by quadruplex attendants will be eliminated.

Recent Telegraph and Telephone Patents.

ISSUED JUNE 13.

996,580. Wireless Telegraphy. To C. M. Green, Lynn, Mass.

ISSUED JULY 4.

996,701. Automatic Cut-Out for Aerial Telephone Lines and the Like. To L. W. Carroll, Anamosa, Ia.

996,770. Combined Telephone and Electric Lamp. To F. J. Kerbel, New York.

ISSUED JULY 11.

997,288. Connecting Circuit for Telephone Exchanges. To Everett D. Hall, New York.

997,515. Signaling Apparatus. To Harry Shoemaker, Jersey City, N. J.

997,516. Receiving Apparatus. To Harry Shoemaker, Jersey City, N. J.

997,594. Telephone Repeater. To Willard Anderson, Longdale, Okla.

997,651. Telegraphic Recording Apparatus. To Thomas McClelland De Bingham, London, England.

997,756. Telephony. To George C. Cummins, Western Springs, Ill.

Personal.

Mr. Thomas A. Edison will sail for Europe, August 2.

Senor Don Camilio A. Gonzalez, director-general of the federal telegraph lines of Mexico, has resigned.

Mr. Louis E. McCabe, a former telegrapher, has been appointed superintendent of the Illinois Central Railroad at Mattoon, Ill.

Mr. Roy W. Howard, general news manager of the United Press Association, New York, is on a business trip to the Pacific coast.

Mr. C. R. Underhill is now connected with the Acme Wire Company, of New Haven, Conn., in the capacity of electrical engineer.

Mr. Fidel Villacorta has been appointed telegraph and telephone inspector for the first zone, Republic of Salvador, Central America, with headquarters at San Salvador.

Mr. G. H. Corse, Jr., of Shanghai, China, has arrived at San Francisco on a two months' visit and will arrive in New York about September 1. He will return to the Orient about October 15.

Mr. T. Buckley, chief electrician Post and Telegraph Department, Wellington, New Zealand, is in New York visiting the telegraph and telephone plants and other electrical industries. He will leave for England and the Continent in about three weeks and return home in November.

Postal Telegraph-Cable Company.

EXECUTIVE OFFICES.

Mr. Clarence H. Mackay, president, sailed for Europe July 11, to be gone six weeks.

Mr. J. F. Skirrow, associate electrical engineer, New York, is spending a vacation at Lake George.

Mr. C. F. Leonard, district superintendent, New York, is absent on his vacation.

Mr. C. A. Richardson, manager of the Boston office of this company, has been advanced to the position of district superintendent with headquarters at Boston, vice A. L. Edgecomb resigned.

Mr. E. P. Tully, manager of the New York office, has returned from Boston where he spent a few days on company business.

Mr. J. L. Fuller, manager of the North American Telegraph Company, at Duluth, Minn., was a recent executive office visitor.

Mr. Charles Many has been appointed manager of the 274 Columbus Avenue office, New York, vice Mrs. Scriver transferred to night duty at the Hotel Imperial.

Mr. Charles A. Richardson, recently appointed district superintendent of the Postal Telegraph-Cable Company, with headquarters at Boston, Mass., is a New Englander by birth, having been born in Newburyport, Mass., a little over forty years ago. He has been with the Postal company for more than a quarter of a century and has advanced from the position of operator to that of superintendent through every intermediate grade. He began his services with the company as operator in New York and remained there for fifteen years, becoming in the meantime traffic and wire chief. On January 1, 1900, he was appointed manager of the Boston office and held this position at the time of his promotion to the superintendency. His wide and long experience with the company and his personal qualities especially fit him for the important duties of his new position, and his appointment gives general satisfaction.

Western Union Telegraph Company.

EXECUTIVE OFFICES.

Messrs. Belvidere Brooks, general manager, G. M. Yorke, engineer, W. N. Fashbaugh, traffic engineer and W. C. Merly, secretary to the general manager are on a business trip in the West which will take them as far as Salt Lake City, Utah.

Mr. A. G. Saylor, general superintendent Eastern Division, New York, is on a short business trip to Maine.

Digitized by Google

Mr. R. W. Whitehead, division plant superintendent at Denver, Col., has been transferred to a similar position in the Western division with headquarters at Chicago.

Mr. A. R. Porte, superintendent Great North-Western Telegraph Company, Ogdensburg, N. Y., was a recent executive office visitor.

Mr. S. G. Bentley has been appointed manager of the Mobile, Ala., office of this company to succeed Mr. C. R. Hughes resigned.

Mr. P. F. Dowd has been appointed manager of the office at 129 Columbus Avenue, New York, vice Mr. H. Putterman transferred to the main office.

Mr. A. J. Lemaire has been appointed manager of the 1647 Broadway office, New York, vice Mr. J. J. Shelley appointed solicitor in the territory of Mr. C. B. McCann, district commercial manager.

The cotton exchange office at New Orleans, La., has been enlarged and fitted out in the most modern manner through the efforts of Manager W. A. Porteous.

The Telephone.

Telephony in Japan.—The Japanese Department of Communications has decided to build a telephone line between Kobe and Arima.

Telephones in New York City.—The number of telephones in use in New York City July 24 was 420,688, an increase of 20,160 since January 1.

Submarine Telephone Cable.—A fifty-mile gutta-percha cable containing Pupin coils has been ordered for use between England and Belgium in telephone service.

Telephone Earnings.—The earnings of the American Telephone and Telegraph Company in the six months ended June 30 were $18,203,000, or about $600,000 more than in the corresponding period last year. Net earnings—$16,421,000—show an increase of $520,000. The surplus after deducting interest and dividends shows a decrease.

Texas Telegraph and Telephone Company Sold.—The Texas Telegraph and Telephone Company has sold its 500 miles of toll lines and other physical property to the Southwestern Telegraph and Telephone Company. The system embraces exchanges at Llano, Mason, Fredericksburg, Marble Falls, Sansaba, and Austin, Tex., and connecting toll lines.

Private Line Telephones in London.—One class of telephone business developed in London is that of the private line between two business houses or a man's office and his home, over which he can speak without going through an exchange, merely lifting his receiver to make a call. The service is fairly cheap, as it carries no operating expenses, and is further attractive because no royalties need be paid to the postoffice on this kind of connection.

Blind Telephone Operators.—The Bloomingville, Ohio, telephone exchange is operated by two persons, man and wife, who are totally blind, and it is stated that the service is very satisfactory to the patrons. An ordinary switchboard is used except that it has a small bar running beneath the drop shutters on the board. When a shutter drops the operator runs his or her hand along the bar until the shutter is touched. By touching the bar just beneath, the number is given the operator by raised figures. The plug is inserted, the desired number asked, and the hand is again run along the bar until that number is reached. Then the connection is made.

Radio-Telegraphy.

Wireless Station for Madrid.—The Spanish Government is about to erect a wireless station in the camp at Carabanchel, near Madrid, the range of which is 300 miles beyond the coast.

Wireless in Forest Patrol.—Assistant Chief United States Forester, Mr. William Potter, will recommend that wireless telegraphy be used instead of the telephone in connection with the patrol of the great forest reserves of the West.

Steering by Wireless.—A demonstration is reported to have been given on the Wannsee, Berlin, of the capabilities of a boat devised by Christian Wirth, of Nuremberg, which is steerable by means of wireless transmission. After the boat had been towed out far into the lake, and it had been ascertained that no one remained on board, the inventor manœuvered the boat by means of transmitting apparatus arranged on a terrace on the shore of the lake, where many spectators were present, including representatives of the army and navy.

Wireless Telegraphy in the Kongo.—Early this year a wireless-telegraphy expedition left Antwerp, Belgium, for the Kongo. This expedition was organized by M. Goldsmith, of Brussels, for the King of Belgium, who has allotted for the purpose part of a fund of 3,300,000 francs ($636,900) to be used each year for the improvement of the Kongo. The purpose of the expedition is to erect several experimental wireless stations and test the practicability of establishing wireless communication with Europe and extending the system throughout the territory of the Kongo. The expedition consists of six men, representing two different companies who are competing for the contract for the complete installation of wireless in the Kongo. These companies are the Telefunken of Berlin and the Radio-Telegraphie of Paris. The former system has been

Digitized by Google

installed at Boma, about 55 miles up the Kongo River, and the Radio-Telegraphie system, at Banana, at the mouth of the Kongo. Two more stations are to be installed by the Telefunken, one at Leopoldville, about 220 miles up the river, and the other at St. Paul de Loanda, about 200 miles south of the mouth of the Kongo. The stations at Boma and Banana are now in operation and have succeeded in establishing communication with each other and with vessels at considerable distances at sea.

Municipal Electricians.

Superintendent of Milwaukee Fire-Alarm System.—The position of superintendent of the consolidated fire and alarm telegraph systems has been created in Milwaukee, Wis.

Fire Alarm System in Factory Buildings.—At the last session of the New Jersey Legislature an act was passed requiring that factory buildings more than two stories in height shall be equipped with fire alarm boxes on each floor, connected by electric wiring to a relay and from the relay to alarm gongs on all the floors, and to an annunciator on the ground floor and to properly located batteries.

Death of Superintendent S. W. Manning of St. Paul.—Mr. S. W. Manning, superintendent of fire alarm telegraph, St. Paul, Minn., was killed by coming in contact with a high voltage wire while investigating some trouble on fire alarm wires at the fair grounds in that city on July 19. Mr. Manning was chairman of the executive committee of the International Association of Municipal Electricians and his sudden death will probably affect the plans for the next convention of that association, which was to have been held in St. Paul, September 12-15.

Obituary.

John C. Lauber, aged 48 years, chief operator for the North American and Postal Telegraph-Cable Companies at Minneapolis, Minn., died at that place July 8.

George C. Pierce, vice-president of the Old National Bank, Grand Rapids, Mich., and an old-time and military telegrapher, died in that city July 15, at the age of 67 years. This is the nineteenth death among the members of the United States Military Telegraph Corps since September last year.

Cable Earnings.—The semi-annual report of the Anglo-American Telegraph Company, according to a London dispatch, shows a decrease of $188,970 in traffic receipts and an increase in expenses of $6,640. Regarding the agreement with the Western Union Telegraph Company the report says it is "settled in principle and detail, but not yet exchanged."

Some Observations on Telephone Transmission.*

BY J. L. MCQUARRIE, OF NEW YORK.

Since the beginning of the industry, telephone engineers and inventors have been confronted by two problems with respect to transmission: First, to increase the possible range of communication, that is, the distance over which it is possible to provide a satisfactory grade of telephone conversation; and, second, to cheapen the methods or means of furnishing this transmission.

The reason for development along each of these lines is at once obvious. The range of telephone transmission can be extended either by increasing the efficiency of the instruments employed, or by increasing the efficiency of the line. The cost of providing telephone facilities can be reduced either by improving the instruments or by cheapening the line while maintaining a given standard of efficiency, since for a given grade of transmission with improved telephone instruments, a cheaper type of line is possible.

One of the most interesting problems concerning telephone transmission is that of the repeater. The demand for an instrument which would relay the voice currents was very early appreciated, and much thought and labor have been devoted to this subject. The problem of the repeater consists really of two problems; first, a device for amplifying weak telephone currents without distorting them; secondly, an arrangement of circuits which will permit repeating both ways without switching. A repeater which accomplishes both of these objects has been employed on the long lines of the American Telephone and Telegraph Company for about six years. This repeater is capable of extending the range of transmission by 40 per cent., which means in terms of 210-pound copper circuit an increase in talking distance of about 250 miles.

The instruments which are employed for telephone transmission must of necessity be of a somewhat delicate nature because the energy with which they deal is of small magnitude. This, coupled with the fact that they are subjected to severe treatment in service, makes it essential that they be of substantial design, and that they be manufactured with great care. Uniformity in the product is also a very important factor—and these requirements are best realized under conditions which provide for the attention of trained experts of long experience.

It was to be expected that the first telephone lines should be similar to the then existing telegraph lines. Iron wire and grounded circuits constituted the early practice, and many years elapsed before proper attention was devoted to the lines to adapt them to the peculiar requirements of telephone service.

*Abstract of paper read at Boston Convention of Association of Railway Telegraph Superintendents, June 26.

Digitized by Google

The first important improvement in the line plant consisted of the introduction of metallic circuits. This change was a measure of necessity to prevent disturbances caused by other electric circuits, as well as to avoid objectionable cross-talk between adjacent telephone lines.

The next improvement of importance in the line plant affecting transmission was the employment of hard drawn copper wire in place of iron. The limitations of iron wire were appreciated as soon as efforts were made to extend the range of transmission, and, while copper had previously been used for electric circuits, it was not suitable for aerial lines because it was too soft. Mr. T. B. Doolittle, an engineer in the employ of the American Bell Telephone Company, developed a process for manufacturing hard drawn copper wire, and this was the first important step toward the realization of long distance telephony.

As the business grew, and the demands for service increased, the congestion of overhead wires in cities led to the employment of cables. At first, as in the case of open wire lines, telephone cables were similar to the then existing telegraph cables. It was soon discovered, however, that owing to cross-talk or overhearing between adjacent conductors, it was not possible to extensively employ grounded telephone lines in cables, and metallic lines, with the two conductors twisted together, were found to be necessary. Practically the only satisfactory telegraph cable at that time was the one insulated with gutta percha. As this was very expensive and also, because of its high capacity, very inefficient, the problem confronting the telephone engineer at that time was the development of a satisfactory telephone cable. A large number of designs of cable were experimented with, but the final type which is now used under all conditions excepting the most severe submarine service, is the dry core paper-insulated lead-covered cable.

Following the development of the hard drawn copper wire, and of the dry core paper cable, some years later an invention was perfected which provided a means for not only extending the limit of telephone transmission, but also for effecting economies in the construction of the lines. Especially in the case of cables the economies are so great as to permit of the use of underground cables between points which, without this means, it would be practically impossible to connect by cables. This is of great practical advantage since overhead lines are notably subject to trouble from storms, while cables are free from such troubles. The invention to which I refer is the use of loading coils in the lines. This invention, more than any of the preceding improvements, marked the application of scientific principles to the problems of telephone transmission.

In the early records of tests on telephone transmission through cables are to be found statements to the effect that the transmission over cable circuits is equally as good as that over open wire circuits. As the length of cable was increased, however, it was soon found that this was not the case and that telephone transmission was reduced very much more by passage through cables than over a corresponding length of open wire line employing the same gauge of copper conductor. It was quite early recognized that, since the cable had very much larger mutual capacity than the open wire line, telephone transmission must be poorer over the cable. This conclusion developed from the scientific work performed by the late Lord Kelvin in connection with submarine telegraph circuits. What was not realized, however, for many years was the fact that in the case of open wire lines there was present to a considerable degree what may be termed, from the point of view of the telephone engineer rather than from a purely physical standpoint, a "corrective element," namely, the self-inductance of the line. In the case of cables, due to the fact that the two wires are very close together, corresponding to the non-inductive winding of a resistance coil which is so familiar to you all, the self-inductance of the circuit is a minimum. In case of the open wire line, the wires being 12 inches or more apart, the self-inductance has a comparatively large magnitude and is of great importance in telephone transmission. For instance, in the case of a No. 8 B. W. G. copper circuit, which has a conductor weighing about 435 pounds per mile, the range of commercial transmission between stations equipped with standard instruments is about 1,000 miles. If we could conceive of the wires being left 12 inches apart so that the capacity would be the same as at present, but in some mysterious manner the self-inductance of the circuit would be obliterated, the commercial range of transmission over this circuit would be reduced to perhaps 350 miles. I present this as an illustration of the importance of self-induotance in telephone circuits. Of course, if we could by some means avoid the capacity in a telephone circuit, we would prefer not to have the self-inductance present. If, however, the capacity is to be present, to obtain an efficient telephone circuit a comparatively large amount of self-inductance should also be present.

It was pointed out that to improve the transmission over open wire lines, the self-inductance that was present should be substantially increased, and that over cables, where the amount of self-inductance was almost negligible, it should be still further augmented in order to obtain the best results, and it was suggested that one method of increasing the inductance of the circuit would be to insert at intervals self-inductance coils, one winding in each of the two wires of a metallic circuit, or else a separate coil in each wire. No one, however, seemingly was able to show the telephone engineer how to introduce these coils into the lines.

Professor Pupin, by mathematical investigation, checked by experiments, about ten years ago furnished the telephone engineer with a practical plan for the employment of self-inductance coils which came to be known as "loading coils," this designation being derived from the analogy of the telephone circuit, with a string loaded with weights at intervals. Without pointing out the complete an-

Digitized by Google

alogy between a motion of waves along a string and the telephone circuit, it may here be said that the telephone current is transmitted in the form of waves, and as these current waves progress along the conductor, they become altered in form as a result of counter influences inductively created by the current wave itself, and, inasmuch as the loudness and clearness of transmission is determined by the accuracy of reproduction of the wave form, and by its amplitude or height, the effect of the action of these inductive influences is to impair the transmission efficiency of the circuit. In seeking a remedy in the case, the object to be obtained is to preserve the original form and amplitude of the wave as far as possible. In the case of the string, it is found that for a given frequency, tension and amount of frictional losses, the larger the mass per unit length the greater the distance a wave of a given amplitude will be transmitted before being reduced in height by a given amount.

Loading has been very successfully employed on open wire lines and on underground and submarine cable circuits. An idea of the improvement in the transmission which results from the use of loading coils may be gained from the statement that where conditions favor loading, the 175-pound copper open wire circuit by loading is made equivalent in transmission efficiency to a 435-pound copper open wire unloaded circuit. In the case of cable, still greater relative gains in efficiency are possible; for example, a No. 19 B & S gauge cable suitably loaded has a higher telephonic efficiency than a No. 10 B & S gauge cable non-loaded. The No. 19 cable conductor weighs but one-eighth of the No. 10.

Phantoming has been employed in the past to produce economy in the telephone plant, because the phantom circuit provides a means for obtaining an additional line from two existing lines. It is but recently, however, that advantage has been taken of the increased efficiency of the phantom circuit to extend the range of transmission. The New York-Denver line lately placed in service, and the Boston-Washington underground cable now being laid, are examples of the latest advances in this branch of the art.

For a long time extensive use has been made of means permitting the simultaneous use of a line for telephony and telegraphy. If the two wires of a metallic telephone circuit are used for independent grounded telegraph circuits, we say the line is "composited;" but if the two wires of the telephone circuit are used in parallel as a telegraph circuit, we say the line is "simplexed." The compositing of a circuit does not limit the possibilities of also using it as one side of a phantom. The composited or simplexed circuits result in large savings, but whether the former or latter should be used depends upon a number of considerations. It may here be stated, however, that in general the use of simplexed circuits presents fewest complications, so that where an adequate supply of telegraph circuits can be obtained by this method it is not usual to resort to composited circuits. This should not be understood as implying that the use of composited circuits involves much complication, since, provided suitably designed equipment has been procured, the operation of composited circuits presents no difficulties. The transmission loss due to the addition of composite apparatus to the two ends of a circuit is just noticeable, being about 10%, or one mile of standard cable. The loss due to simplexing depends upon the type of simplex employed, whether "bridged retardation coil" or "repeating coil," and in each instance upon the type of apparatus used. In the case of small cheap repeating coils sometimes employed, the loss may be serious, being perhaps 50% or six or seven miles of cable.

In the case of composite apparatus especially, it is important that it should be carefully designed so that the telephonic efficiency will be a maximum and the chances of interference due to noise between the telegraph and telephone made a minimum.

(*To be continued.*)

Turner Monument Fund.

Interest in the Turner monument to be erected at Turner, N. Y., to commemorate the sending of the first telegraphic train order continues and contributions toward the fund are being received. As already announced the list is still open for further contributions, and will remain open for some time yet. In the meantime the committee is actively engaged on the plans with the co-operation of Mrs. E. H. Harriman's representative, Mrs. Harriman having very generously offered to meet the cost of the monument and the necessary cutting.

Those who have not sent in their subscriptions toward the fund are urged to do so at once in order to facilitate the work of the committee; and all interested in the railroad and railroad telegraph service should be represented in this interesting project. The fund committee consists of E. P. Griffith, superintendent telegraph, Erie Railroad, Jersey City, N. J., chairman; Charles Selden, superintendent telegraph, Baltimore & Ohio Railroad, Baltimore, Md.; J. B. Taltavall, TELEGRAPH AND TELEPHONE AGE, New York; E. A. Chenery, superintendent telegraph, Missouri Pacific Railroad, St. Louis, Mo.; W. J. Camp, electrical engineer, Canadian Pacific Railway, Montreal, Canada; Col. W. B. Wilson, president Old Time Telegraphers' and Historical Association, Holmesburg, Philadelphia; F. J. Sherrer, secretary Old Time Telegraphers' and Historical Association, New York. All remittances should be made to Mr. J. B. Taltavall, TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York, who has been elected treasurer of the fund. All contributions are acknowledged in the columns of TELEGRAPH AND TELEPHONE AGE, and the funds deposited with the Washington Trust Company, New York, as soon as received.

Contributions received up to date are as follows: Previously acknowledged, $1,641.25; W. B. Latta, El Paso, Tex., $2.00; Wm. Maver, Jr., New York, $2.00; total, $1,645.25.

A Voltmeter Loop Test.

BY R. L. GILLES, TOPEKA, KAN.

In offices where there is no bridge the following test will be very useful in locating trouble in cables or telephone lines. The accuracy of this test will depend on the reading of the deflections and the resistance of the wires being equal.

The drop in voltage is directly proportional to the resistance; the resistance is directly proportional to the length of wire; therefore the drop in volts is directly proportional to the length of line.

Suppose we have a wire 100 miles long divided into 25-mile sections, as shown in Fig. 1. If the voltage between A and E measures 100 the drop

FIG. 1.—DIAGRAM OF ONE-HUNDRED MILE CIRCUIT.

from A to B will be 25 volts, also between B and C; C and D; D and E; likewise the drop will be 50 volts from A to C; B to D; and C to E. Suppose now this line to be doubled back at C to form a loop (as illustrated in Fig. 2) and grounded at D.

The drop from E to D is 25 volts and the drop from D to A is 75 volts. Then $25:75::ED:DA$, and also drop ED: length E to D:: drop EA: length E to A, therefore the distance E to D: drop ED:: distance E to A: drop E to A, or distance

$$E \text{ to } D = \frac{\text{drop } E \text{ to } D \times \text{distance } E \text{ to } A}{\text{drop } E \text{ to } D + \text{drop } D \text{ to } A}$$

The sum of the two readings will not always equal the voltage at the loop terminals, due to the resistance in the ground and the variation in currents when the voltmeter is shunted across the portions of the loop. This error cancels out, however, and the proportion is correct.

If using gravity batteries in this test, all wires should be taken off so as to get a steady reading.

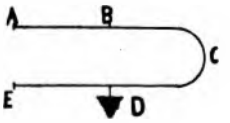

FIG. 2.—CIRCUIT LOOPED.

It is necessary that all equipment be taken from the line and a good short be put on beyond the trouble. An illustration of the test is shown in Fig. 3: Let X and Y be two lines and Y grounded at G and a short circuit put on the line at AB.

Reading $X' = 28$ volts

Reading $Y' = 12$ volts

$$\text{Distance } Y \text{ to } G = \frac{12}{28+12} \times 200 = 60$$

Length of loop $XABY = 200$ miles

or distance to the ground is 60 miles from Y.

In case X and Y are telephone wires and Y is crossed with a telegraph wire or other wire, the test would be the same, only using the crossed wire in place of the ground for taking the readings.

In case of a short circuit on a pair, if the short circuit be a solid one, this test can be used by put-

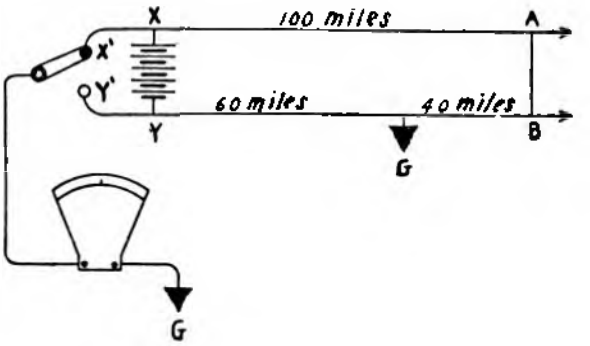

FIG. 3.—DIAGRAM OF TESTING ARRANGEMENT.

ting on a ground between the office and the short as follows:

$$\text{Distance around loop} = \frac{\text{Distance to ground} \times X' + Y'}{Y'}$$

$$= \frac{60 \times 40}{12} = 200 \text{ miles}$$

or the distance to the short circuit equals half of the loop distance, or 100 miles.

If possible, it is best to have the wires under test opened at a convenient place beyond the portion under test so as to remove any error due to another trouble on the same wires. The distance around the loop or to the ground, as the case may be, can be calculated from time tables or from a map drawn to scale.

Apparatus for Charging Storage Batteries.*

Storage battery installation may be of two general types—stationary or portable. Stationary batteries may be concentrated at a single location, near the power plant, as in the case of electric interlocking, or they may be distributed at a number of locations, and charged from a transmission line, as in the case of automatic signals. Portable batteries are charged at a concentrated location and distributed for use. Because of the nature of the battery applications, charging appliances for signaling may be divided into two types; first, those for charging a battery at or near a power plant; second, those for charging through a transmission line.

The first type will ordinarily require a minimum of about two volts and a maximum of about 175 volts, with a minimum of 5 and a maximum of 40 amperes. The second case will require, for transmission line of average length, from 500 to 600

* Abstract from paper presented by H. K. Ferguson, R. E. Russell and E. E. Kimball at the meeting of the Railway Signal Association, New York, June 14.

Digitized by Google

volts, with any economical charging rate. This may, in some instances, be surprisingly low, with good results. The usual rate is from 4 to 10 amperes. In order to strike a fair average, we have based the following discussion upon a 5-kilowatt requirement, which is rather above, than below, the usual size.

If current can be secured from an outside source the purchase and operation of an expensive prime mover may frequently be omitted with a consequent reduction in initial and operating costs. If not there is, of course, no alternative except the installation of a complete power plant for battery charging.

The most desirable and economical condition and the one least frequently found in actual practice, is when direct current can be secured at a fair price, and at a practically constant voltage, equal to, or only slightly exceeding, the maximum voltage required for battery charging. In cases of this kind, regulation between the maximum and minimum potentials required may be readily accomplished by the use of suitable resistance or rheostats. No rotary machines are necessary, but only a simple switch-board panel, for mounting the proper instruments and regulating and protecting devices. Aside from this solution, any battery-charging plant will have to embody one or more of the following types of apparatus: (1) direct current-direct current motor generator set; (2) alternating current-direct current motor generator set; (3) mercury arc rectifier; (4) dynamotor; (5) rotary converter; (6) steam turbine driven unit; (7) steam engine driven unit; (8) gasoline engine driven unit; (9) switchboard panel; (10) battery charging panel.

The first five types are converters of electric energy, and, adapted for battery charging only with an external source of current. Types six and seven may ordinarily be taken to pre-suppose an existing steam supply, as the installation of individual boiler capacity would be prohibitively expensive. Type eight, the gasoline outfit, is the best practical outfit at present, where no external source of energy exists. Type nine is accessory to the preceding items, with the exception of the mercury arc rectifier, which requires no additional switchboard. Type ten is also accessory, but used only where several sets of duplicate battery at concentrated locations require special controlling devices not convenient for mounting on the panel.

Items four, five and six will not prove applicable to many railway signals installations. The dynamotor is a machine with two independent armature windings on the same core, each winding having a separate commutator. One field winding, only, is provided for both armature windings. Difficulties with the voltage regulation, and the fact that these machines are more or less special, and consequently rather expensive, have so far prevented their general application to signal battery charging. The rotary converter, in small sizes, is in little demand, and is likely, in consequence, to be rather high in price. Besides this, the impressed alternating current voltage bears a constant ratio to the direct current voltage generated by the rotary converter, so that the direct current voltage can only be changed by regulating the alternating current voltage. The ratio of alternating current to direct current is .6 for three-phase circuits, and .7 for single and two-phase circuits. Steam turbines, in small sizes, are not ordinarily as efficient or as easily regulated as the small steam engine. Also, they are not so frequently used, and, in consequence, are more expensive.

The field is thus limited to motor generator sets, rectifiers and steam engines, where electric or steam mains are available, and to the gasoline engines, for isolated locations.

The efficiency of the mercury arc rectifier is approximately constant at 80 per cent and of motor generator sets from 60 to 72 per cent, within limits at which they are operated. The thermal efficiency of the gasoline engine is much higher than that of the steam engine, but this advantage is usually much more than offset by the cost of fuel. In general, it may be said that the first cost of the mercury arc rectifier will usually be least; motor generator sets will be only slightly higher, with steam engine sets next, provided boiler capacity is available, and gas engine outfits most expensive. These types will rank in the same order as regards the amount of floor space required.

Motor generator sets are in common use for signal battery charging. They should be preferably direct connected, because more reliable, and requiring less floor space. They are readily adapted for all of the current and voltage requirements for signal work. While constant voltage is desirable for driving the motor, even trolley current, fluctuating rather widely, may be used, with a proper automatic voltage regulator. A particularly desirable method of operation may be obtained by using a small motor generator set for continuous operation, with the battery, load and generator all in multiple. This method, which is ordinarily known as "floating the battery," permits the generator to carry most of the load, and charge the battery at a slow rate. When heavy current output is required, and the generator voltage is pulled down, the battery helps out the generator by feeding into the circuit in parallel with it. The battery is also available as a reserve to carry the load for some time in case of a failure of the power supply or motor generator set. The shunt wound type of generator is best adapted for battery charging, because of convenience of voltage regulation, a primary essential for any generator for such service. Alternating current motors for alternating current-direct current sets should be three-phase if it is possible to obtain three-phase power service, because a three-phase motor is usually smaller, and less expensive, and the small sizes require no starting apparatus. Some phase-splitting starting device is necessary with any single-phase motor.

Digitized by Google

In sets of odd size, where direct connection would be expensive, because of special speeds or sizes, an alternative is presented by the use of a "silent chain drive," which is reliable, requires much less floor space than any possible belt connection, and may sometimes prove economical in first cost, without increasing operating expense.

The mercury arc rectifier with the improvements made in recent years is proving to be one of the most valuable devices for battery charging. These rectifiers are complete in themselves, requiring no apparatus not included within the smallest floor space required for any battery charging outfit. They are made in standard sizes ranging from zero to 175 volts, direct current, and from 10 to 40 amperes. This range of voltage limits the rectifier at present to battery charging at concentrated locations, and for short transmission lines, as its maximum voltage is not high enough to operate a long series charging line successfully, even at a low charging rate. Ordinarily the rectifier is designed for operation on 60 cycles, at 110 volts or 220 volts, single-phase alternating current, but it may readily be adapted for other voltages, or frequencies down to 25 cycles.

Steam driven units can be obtained in small sizes, adapted for steam pressure as low as 80 pounds. These sets are useful wherever steam pressure may be had. Steam sets are ordinarily provided with a heavy fly-wheel and closely regulating governor, which results in close speed regulation, and practically constant voltage. Consequently, no automatic regulators of any sort are necessary or advisable.

With the present cost of fuel, gasoline engine sets are more expensive in operation than any of the previously mentioned outfits. They require some cooling apparatus beside the engine and generator. With slight modifications, they may be operated by either gasoline or gas. They are built with various numbers of cylinders, for either two or four cycle operation. When reliably built, and of good design, the gasoline engine is, however, undoubtedly the best, and practically the only economical prime mover for battery charging service at isolated locations.

New Form of Electric Cable.

Mr. J. H. Cuntz, of Hoboken, N. J., has been granted two patents on a special form of cable and on electric wave transmission over underground and submarine cables.

The first patent relates to the construction of a cable for wholly or in part counteracting the effects of capacity by increasing the inductance proportionately.

By Mr. Cuntz's method of construction a cable can be produced with an inductance as large as required under any given conditions, and what is more important, the amount can be predetermined and the elements of the cable so adjusted as to secure the proper amount in a simple and practicable manner.

In the construction of the cable the conductor is carried in a helical path on a paramagnetic core which increases the inductance of the line.

The last three claims of the patent read as follows:

16. A long-distance electric transmission line having a non-current-carrying core, and an insulated conductor wound in an open coil about said core so as to neutralize suitably the electrostatic capacity of the line.

17. An electric circuit comprising a conductor substantially continuously wound to produce inductance sufficient in amount to suitably counteract the capacity of the circuit, and a magnetizable core for said circuit.

18. In an electric circuit, the combination of a magnetic core, a conductor so disposed about said core as to introduce inductance in a continuous manner throughout the length of the circuit so as to counteract adequately the electrostatic capacity of the circuit, and insulating material surrounding said conductor.

Mr. Cuntz's second patent relates to the distribution of inductance in such a manner as to counteract the effect of distributed capacity, more particularly on metallic circuits, by means of the specially constructed cable described. Such circuits may be used for telephone, telegraph, power transmission and all other purposes.

The last two claims of the patent read:

4. In an electric circuit, outgoing and returning conducting wires substantially continuously wound, in opposite senses, to create inductance sufficient in amount to suitably counteract the capacity of the circuit, and a magnetizable core for said wires extending substantially throughout the length thereof, the said core being metallically discontinuous.

5. In a system of telephone transmission, a complete metallic circuit, a magnetic core extending substantially throughout the circuit, and windings of the induction coil of the microphone transmitting apparatus disposed about said core.

Unbreakable Insulators.—An insulating substance of great toughness is being introduced in England and the claims made for it should appeal to telegraph and telephone companies. It is claimed that insulators made of this special composition are bullet-proof as well as unbreakable. The material is weather-proof and almost indestructible, and the screw threads are accurately cut, so that they are easily fitted to the supports, without the use of cement. The insulation resistance of the insulators, as tested in water at Faraday House, was over half-a-million megohms after seven days' immersion in brine, the insulation resistance was about 100,000 megohms, and on applying an alternating pressure at 50 cycles per second the insulation was not broken down until pressures exceeding 13,000 volts were attained. Fired at with shot-gun the insulators showed merely superficial injuries.

Improvised Repeaters.

BY C. A. COOK, PORTLAND, ORE.

The writer was called upon to supply, at short notice, single-line repeaters in addition to the regular equipment. There being eight or ten Atkinson half sets at hand these were adapted for use as full-sets in the manner shown in the accompanying diagram. There was, however, added to each a three-point switch, the lever of this switch being connected to the ground terminal of the transmitter coils. The left disk of the switch was connected to the ground wire which was removed from the ground terminal so that when the lever was thrown to that side the set was practically unchanged. The right disk of the switch was connected to the regular local feed wire of say 26 volts.

In the illustration only one half set is shown, the other half being an exact counterpart and connected with it by means of the connecting cord shown at the right of the diagram.

To use any two half-sets thus equipped as one full-set, insert their duplex wedges in a shorted jack as shown, and the two half-sets then will operate together as one full repeater; their main-line single wedges of course being inserted in the lines to be repeatered.

The convenience of this arrangement is manifest inasmuch as the half-set main-line wedges are usually distributed along the different sections of the switchboard, and their duplex wedges grouped in front of the loop-board, where any two may be coupled together in the spare-jack. This jack, it will be seen, serves to connect the face of one duplex wedge to the back of the other, and vice versa, thus placing the transmitter of one set under control of the relay of the other set.

This makes an excellent, quick-breaking full-repeater, and one that may be relied upon on bad-working wires; and it has given such good results that a number of sets have been similarly equipped. Another point in favor of this arrangement is that its use as a full repeater does not in the least detract from its utility as a half-set.

Multiplex Telegraphy and Telephony.

At the recent convention in Chicago of the American Institute of Electrical Engineers, Major George O. Squier read a paper on "Multiplex Telephony and Telegraphy by Means of Electric Waves Guided by Wires."

Major Squier gave the results of experiments made by him at Washington to determine the feasibility of superposing on an ordinary telephone line one or more separate telephonic circuits actuated by high-frequency currents that would not interfere with one another. His idea was to use frequencies above the limit of audibility, viz., from 15,000 to 100,000 cycles per second. The telephone line used in the experiments had a length of about seven miles. It was a twisted pair carried in lead-covered cable from the Bureau of Standards through three telephone exchanges to the laboratory of the Signal Corps. With the exception of 3,400 feet, all the cable was underground. The line resistance was 776 ohms, and the capacity 0.69 microfarads. A specially constructed 100,000-cycle generator was used as the source of the high frequencies. The first tests showed that frequencies from 30,000 to 100,000 could be impressed on the line without being detected in the ordinary telephone receivers. The line was then equipped with the ordinary telephonic apparatus at each end and a high-frequency equipment of the wireless type was also placed at each end; the latter included a microphone transmitter and a perikon crystal detector. By means of a double throw switch an interrupter could be substituted for the microphone, thus permitting high-frequency telegraphic signals to be sent and received. Speech was transmitted and received successfully over one of the wires with ground return. At the same time the ordinary low-frequency telephone equipment was successfully used without interference from the high-frequency currents, thus achieving true duplex telephony. By the insertion of tuning inductances and condensers the transmission was improved and cross-talk and earth disturbances eliminated. An audion detector was used in the final experiments and both bridging and series arrangements successfully used. By holding one telephone receiver to one ear and the other receiver to the other ear, the receiving operator could hear two entirely different conversations simultaneously over the same pair of wires. Duplex-diplex Morse and high-frequency telegraphy was also carried on. Many measurements of electric waves at frequencies from 20,000 to 100,000 were also made and numerous resonance curves drawn for the open and closed line. The author in concluding his paper called attention to the fact that his system is not intended to supplant, but rather to supplement, the present systems. He contended that his experiments show the value of a metallic wire guide for the energy of electric waves, thus furnishing a directive wireless system and solving the problem of interference of messages, at the same time reducing the distortion of speech.

Wireless Telegraph Waves from the Sun.—In a certain sense every shining star in the heavens is constantly sending out spherical electromagnetic waves within the range of visual perception, besides probably many longer waves, outside of that range. In this particular sense we are constantly receiving wireless telegraph waves from every visible orb, and the message received is not news but light. Moreover, since all animal energy is derived from plants, and all plants build up their substance from the energy contained in the sunlight they receive, it follows that all our muscular energy is derived indirectly from wireless telegraphy waves received from the sun.—From *Wireless Telegraphy and Wireless Telephony*, by Dr. A. E. Kennelly.

ADDRESS ALL COMMUNICATIONS TO
J. B. TALTAVALL, - Editor and Publisher
253 BROADWAY, NEW YORK.
T. R. TALTAVALL, Associate Editor.

CABLE ADDRESS: "Telegage," New York.
Telephone: 6657 Barclay

CHANGES OF ADDRESS.—In ordering a change of address the old as well as the new address must be given.
REMITTANCES to Telegraph and Telephone Age should be made invariably by draft on New York, postal or express money-order, and never by cash loosely enclosed in an envelope. By the latter method money is liable to be lost, and if so remitted is at the risk of the sender.

August 1, 1911.

Seeking Employment in New York.

It seems to be the ambition of many operators, particularly young men, to obtain a position in the New York office, thinking, probably, that a course of experience in this city will finish off their telegraphic education. Many such operators are possessed with the idea that to be able to say that they have worked in the New York office gives them a telegraphic standing that they could not otherwise obtain, and that it is a sufficient recommendation for a position elsewhere.

To those who have such yearnings we would offer a word of caution, especially to men who have families. We have frequently been asked for advice by operators and even managers in small towns who have families and are relatively well off in their own communities as to the advisability of their coming to New York. To such requests we have only one reply to make and that is: "Don't"—with a big D and the other three letters big as well. To make such a move is rank folly. The thought is almost unbelievable that a man with a family, who possibly has attained a position of prominence in his little town could for a moment entertain the idea of surrendering a life of comparative peace and happiness for one of turmoil and discomfort, but it is true that there are such cases.

It is hardly necessary to state that a man with a family in New York receiving the ordinary salary paid to operators will find it uphill work indeed to live as comfortably as he could on less salary in a smaller town.

With young unmarried men the case is slightly different but even they should move with caution. An operator in a small community can, if he has any ambition at all, become prominent and influential, but in crowded cities like New York the individual cannot make himself felt to so great an extent. If wishing to get a taste of New York life come for a visit only and not with the intention of making it a place of permanent residence.

Cupid in Telephone Exchanges.

Telephone companies frequently complain of the losses in the ranks of their female operators by marriage, and strange as it may seem, the companies themselves are largely to blame for this state of affairs, if one may judge from the employment qualifications of a company in a western city. This company requires applicants for positions as operators to be of good character, have good sight, good hearing, a pleasant voice, good health, obedient, honest, industrious, polite, of good temper and have no disposition to pry into or discuss the affairs of others. It is no wonder that telephone companies are hampered by cupid when they employ such perfect specimens of womanhood and their subscribers find it out.

Airships and Wires.

Another strong argument in favor of placing telegraph and telephone wires underground is found in the increasing use of balloons and airships. At first glance the relationship between the two ideas seems to be remote, but when a balloon or an airship gets entangled with an aerial line it supplies some food for thought. Such an occurrence actually took place recently in a western town. The time may soon come when airships will be so numerous that telegraph and telephone companies will, for their own protection, be compelled to surrender the air to the human birds and fall back entirely upon the tender mercies of mother earth.

High Tension Wire Crossings.

We conclude in this issue the report of the High-Tension Wire Crossings Committee of the Association of Railway Telegraph Superintendents which was submitted to and approved by that body at the recent Boston convention. This report is an important one and represents the results of the careful joint deliberations of committees representing the National Electric Light Association, the American Railway Engineering and Maintenance of Way Association, the American Railway Association, the American Institute of Electrical Engineers and the Association of Railway Telegraph Superintendents, but strange as it may seem the telegraph and telephone companies—really the ones most vitally interested—were not represented. These, however, have been invited to participate in the further work of the committees.

All interests concerned should co-operate in the effort to standardize the practice of providing pro-

Digitized by Google

tection against physical crosses between high and low potential wires, such for instance as electric light or electric railway wires and telegraph and telephone lines. Such crosses are at all times a positive menace to life and property, and the object of the work of the joint committees has been to minimize these dangers by removing the cause as far as possible.

The recommendations of the committee are very complete and seem to provide for every contingency. The report in itself, however, is ineffective; its provisions must be carried into practice and every company concerned should cooperate in the work.

Automatic Systems in Handling Cable Business.

Considerable light was thrown upon the practical operation of the Wheatstone system, the siphon recorder and the automatic printing system as used by the Western Union Telegraph Company, in the discussion by Mr. A. G. Saylor of Mr. Maver's paper read at the recent Boston convention of the Association of Railway Telegraph Superintendents on "High Speed Automatic Perforators, or Perforator Receivers," and printed in the July 16 issue of this paper. Relatively few telegraphers have any practical knowledge on the modern methods of operation of these systems, and for this reason the information imparted by Mr. Saylor will be welcome. Another reason that will render it more valuable is the fact that it comes from a high official of the Western Union Telegraph Company and is therefore reliable and authentic.

The keynote of Mr. Saylor's remarks is speed, and it is interesting to learn how the reduction of time-losses has been accomplished in handling cable business. It is pointed out that these improvements do not always mean economy in cost of operation, but they do effect a saving in time which is the factor of prime importance in cable service.

Principles of Conduct.

To achieve success a man should first convince himself that he is in a congenial business. Whether it be a trade or a profession—both are honorable and profitable—let him satisfy himself above all else that it enlists his personal interest. If a man shows that he has his work at heart, his success can be relied upon. Personal interest in any work will bring other things; but all the other essentials combined cannot create personal interest. That must exist first; then two-thirds of the battle is won. Fully satisfied that he is in the particular line of business in which he feels he has a stronger, warmer interest than in any other, then he should remember:

First—That, whatever else he may strive to be, he must be absolutely honest. From honorable principles he never can swerve. There can be no half-way compromise.

Second—He must be alert, alive to every opportunity. He can not afford to lose a single point, for that single point may prove to be the very link that would make complete the whole chain of a business success.

Third—He must ever be willing to learn, never overlooking the fact that others have long ago forgotten what he has still to learn. Firmness of decision is an admirable trait in business. The man whose opinions can be tossed from one side to another is poor material. But life is full of errors, and caution is a strong point.

Fourth—If he be wise he will entirely avoid the use of liquor. If the question of harm done by intoxicating liquor is an open one, the question of the actual good derived from it is not.

Fifth—Let him remember that a man's strongest recommendation is his respectability. Some men, apparently successful, may be flashly dressed, loud in manner, disrespectful to women and irreverent towards sacred things. But the man who is respectable always wears best. The way a man carries himself in his private life oftimes means much to him in his business career. No matter where he is, or in whose company, respectability, and all that it implies, will always command respect.—*The Pacific Telephone Magazine.*

Wireless Telegraph Detectors.

When the high frequency currents of a wireless system strike the detector a weak pulsating direct current is set up. This action is due to a peculiar rectifying property of the mineral. The receiving range of a station is not as much dependent upon the aerial system as it is upon the adjustment of the tuning circuits and the detector.

Certain minerals and crystals, principally members of the carbon and sulphur groups, possess the peculiar property of rectifying electrical oscillations and converting them into a pulsating direct current. These crystals conduct the current better in one direction than in the other. In the case of a current having a potential of ten volts and applied to the ends of a carborundum crystal the current may be one hundred times greater when flowing in one direction than when flowing in the other. This ratio decreases as the voltage is raised, for with 25 volts it may be only about forty times greater. The crystals when properly inserted in the aerial circuit are enabled to rectify the oscillations and produce sounds in the telephone receivers without the aid of a battery.

Mr. J. M. Barnes, of St. John, N. B., writes: "In renewing I wish to say that the AGE is very helpful in keeping me in touch with the changes and improvements connected with telegraphy, and the articles by Mr. Jones each month should be read and studied by all who purpose making their living at this business."

Revised Instructions on Quadruplex Installation and Operation.

The engineer of equipment of the Western Union Telegraph Company, Mr. W. E. Athearn, has issued revised instructions pertaining to quadruplex installation and operation,* which are printed in the June number of the *Journal of the Telegraph*.

The line resistance box which was originally intended to contain only one set of resistance coils for use in the main line under certain specified conditions, has been redesigned so as to include another set of similar resistances to be used in the artificial

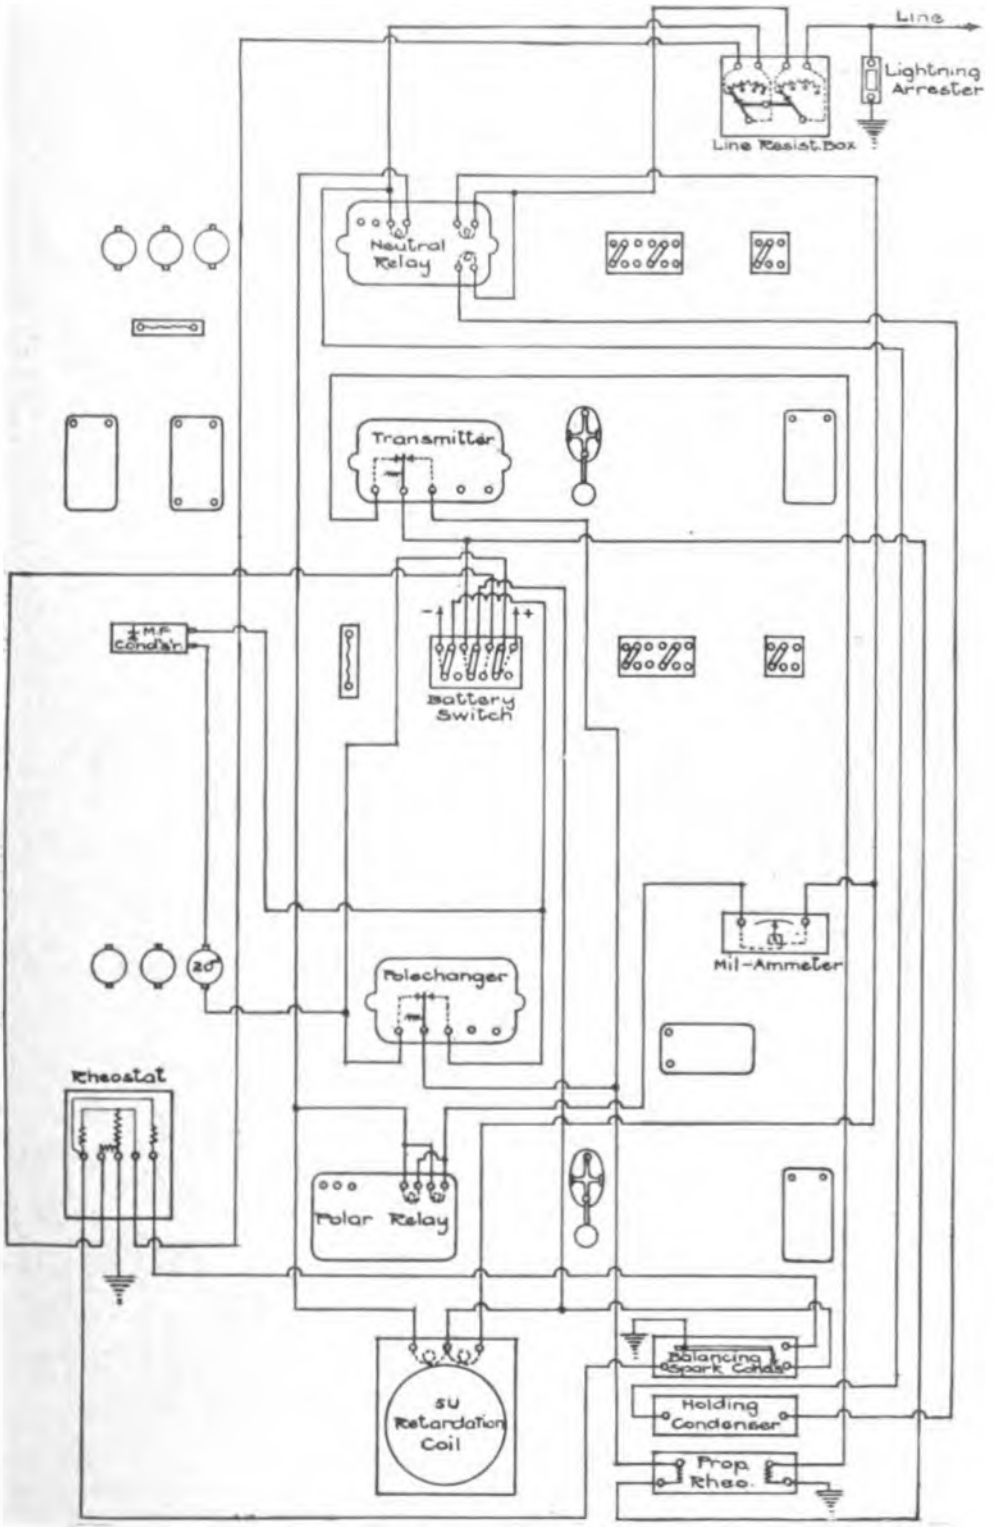

FIG. 1.—WIRING DIAGRAM OF MAIN LINE CIRCUITS

*See Telegraph and Telephone Age, March 16 and April 1.

Digitized by Google

line as compensation for such added line resistance.

New instructions are given covering the "Centering of Polar Relay," "The Transmitting Appliances," "Transmitting Apparatus Adjustments," "Line Resistance Box," and "The Quadruplex Repeater."

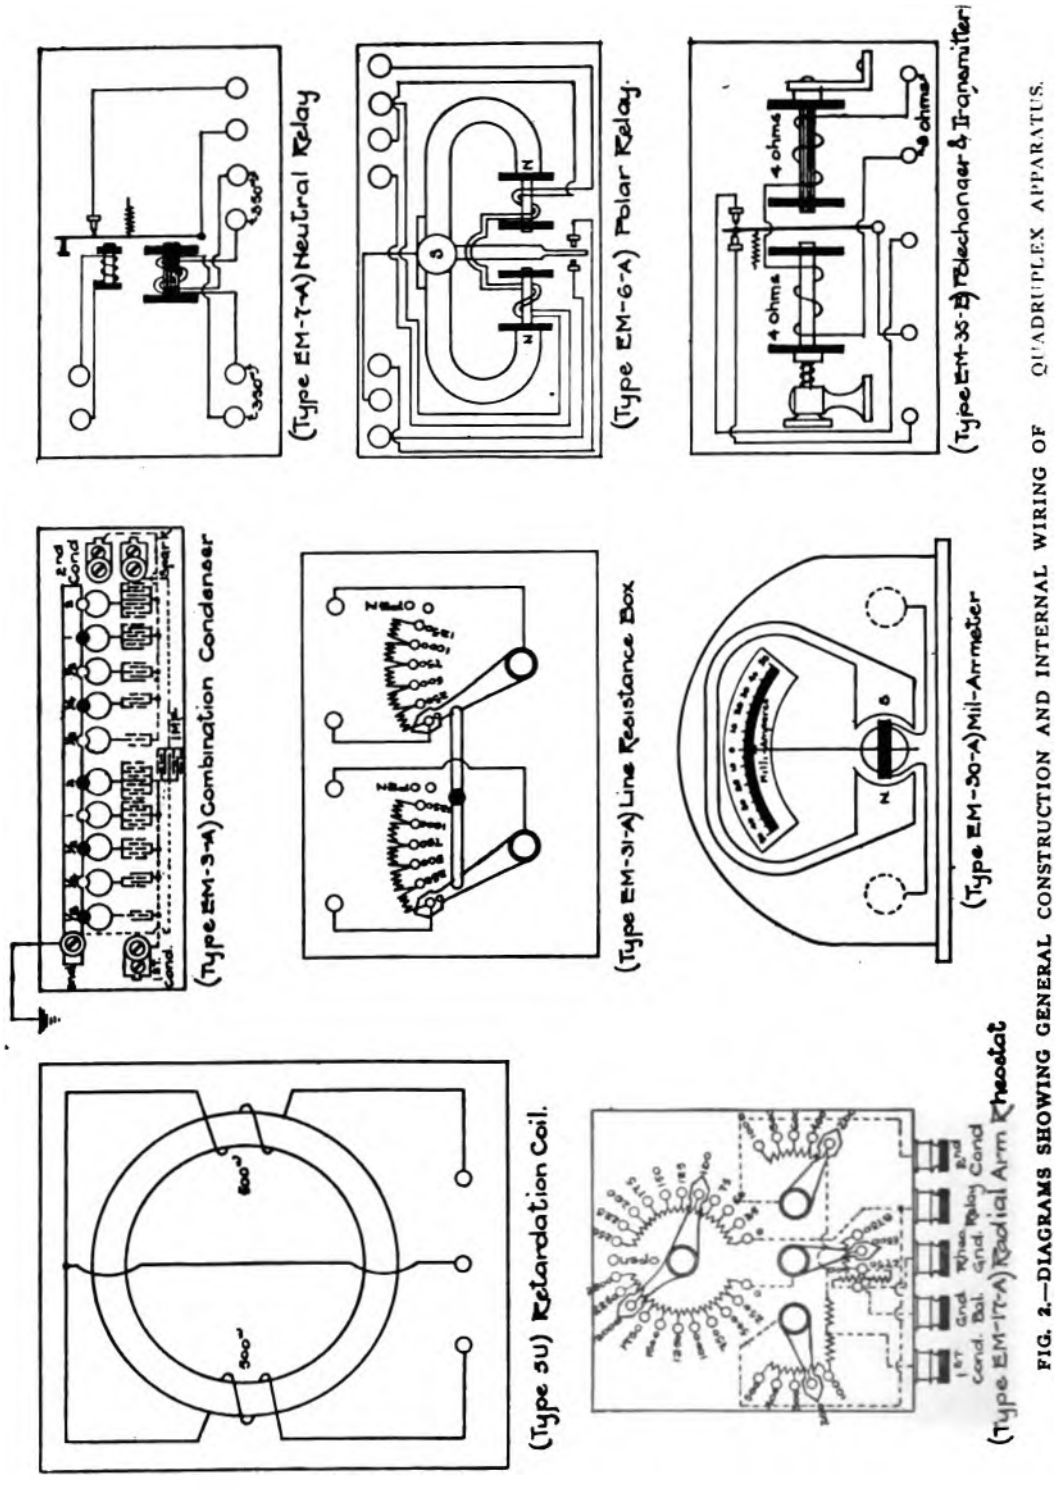

FIG. 2.—DIAGRAMS SHOWING GENERAL CONSTRUCTION AND INTERNAL WIRING OF QUADRUPLEX APPARATUS.

CENTERING OF POLAR RELAY.—In order to center the relay (which course is always advisable in the initial stages of adjustment), first throw the double lever of the line resistance box (Fig. 1) over to its extreme right hand position, which will open both the main and artificial lines. Then set the armature lever midway between the relay cores, leaving an air gap of about 1-32 inch on each side. Afterwards adjust the limiting stops until the play of the

Digitized by Google

lever between them is just sufficient in amount to prevent sticking, and ensure clear breaking of the contact points.

THE TRANSMITTING APPLIANCES.—The form of polechanger and transmitter shown in Fig. 2 is specially designed for rapid action, and to minimize the "interval of no current" when acting in the capacity of current reverser.

The armature of this instrument is placed between two short electromagnets connected in series with each other, one of which (that to the left of the armature) is provided with a solid iron core enclosed in a copper cylinder or jacket so as to make it less active than the other electromagnet, the core of which is of laminated soft iron in order to hasten the rise and fall of the magnetism developed therein. The movements of the armature lever are greatly accelerated by this arrangement, which reduces the

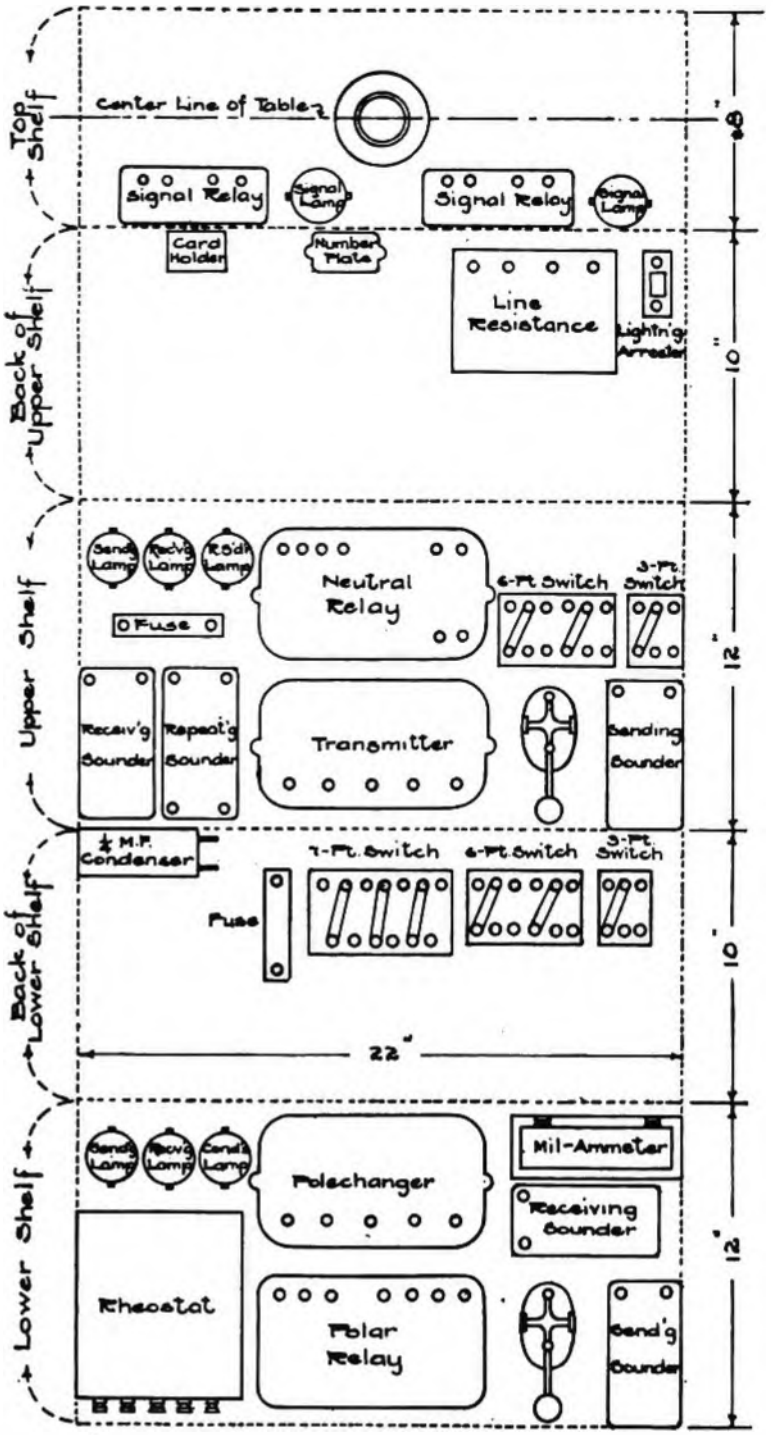

FIG. 3.—DIAGRAM SHOWING LOCATION OF APPARATUS ON REPEATER TABLES.

Digitized by Google

time interval in the passage of the armature between its battery contacts and correspondingly increases the working margin of the neutral relay at the distant station.

an ordinary receiving blank) between the armature and core of the right hand electromagnet, which latter should then be permanently fixed in that position.

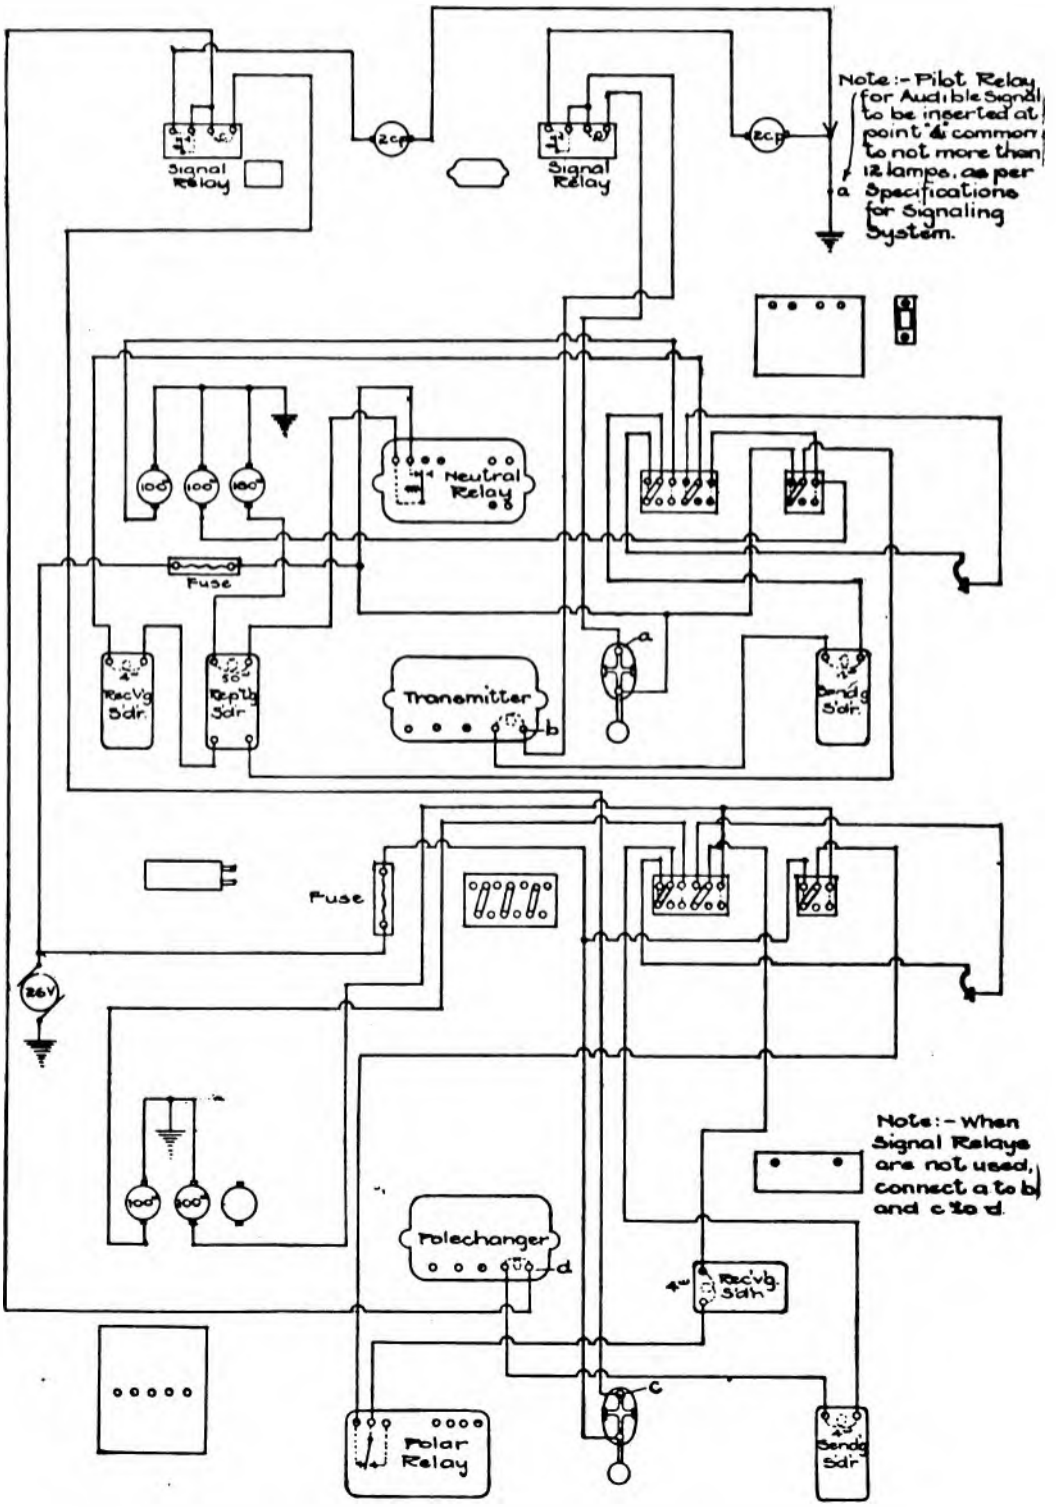

FIG. 4.—WIRING DIAGRAM OF QUADRUPLEX LOCAL CIRCUITS.

TRANSMITTING APPARATUS ADJUSTMENTS.—The coil adjustments of both polechanger and transmitter should initially be such as to leave an air space of about 1-64 inch (or not less than four thicknesses of

The other electromagnet is arranged to move back and forth in the usual way, but its most effective position will generally be found at a point where (with the local circuit closed) the armature rests in-

Digitized by Google

differently on either of its contact stops when placed there by the finger.

The play of the polechanger armature between its battery posts should be as small as is possible without creating a tendency to "arc," which is liable to occur at the breaking of battery contact. To minimize such tendency, a small ¼ m.f. condenser in series with a 20-ohm resistance lamp is now placed across the battery leads (see Fig. 1).

The sparking that appears at the making of battery contact represents the static discharge from the main and artificial lines. The particular object of the spark condenser is to open up an inductive path to ground for this discharge, the effects of which are thereby diminished at the contact points of the polechanger.

Line Resistance Box.—This box (shown in the upper right hand corner of Fig. 1) contains two separate and independent sets of graduated resistance coils, each aggregating 1250 ohms, and so arranged that resistances in equal amounts can be simultaneously cut into or out of both the main and artificial lines by one and the same movement of the double lever with which the box is provided.

The primary object of the auxiliary line resistance is to afford a means for increasing the electrical length of short quadruplex circuits, in order that the latter may be successfully operated on potentials ordinarily used in connection with comparatively long circuits.

It may also be employed to advantage in reducing the strength of earth currents on lines between whose terminal ground plates potential differences exist that would be detrimental to the working—particularly of short quadruplex circuits.

The use of this resistance may occasionally be desirable on the longer circuits under such changeable weather conditions as might seriously affect the working by disturbing the line balances. The insertion of the line resistance under these circumstances, would have the effect of removing the main line wire from the immediate vicinity of the home apparatus, which would then be less susceptible to the alterations in magnetism brought about by leakage variations.

Whenever a change of this character has been made in the line resistance, the distant office should be apprised of the fact in order that any rearrangement of the balance rendered necessary thereby may be suitably effected at that office.

The Quadruplex Repeater.—The repeating apparatus is in every way identical with that at the terminal stations, and the location of its various parts upon the multiplex table at either a terminal or repeater station is specifically indicated in Fig. 3.

The Use of Quadruplex Sets for Duplex Working.—When the weather conditions are such as to render quadruplex working impossible, the circuit may be operated as a polar duplex by closing the second side transmitter at both stations.

To avoid the overheating of apparatus by excessive current under these conditions a sufficient amount of resistance should be added to the circuit by means of the line resistance box to reduce the incoming current to a value that will produce a deflection of not more than 10° on the mil-ammeter scale.

If the leakage along the line be fairly well distributed this extra resistance should be split up between the two offices, equal amounts being preferably inserted at each end of the circuit; but where the insulation of the line is low at one end, and more or less normal at the other end, the larger portion of this resistance should be inserted at the station nearest which the bad weather conditions prevail.

Local Wiring of Quadruplex and Duplex Sets.—Attention is called to the fact that under the old method of local wiring, the compensating resistance lamps are—at many offices—located in the extension cords which serve the purpose of connecting together such different sets of multiplex apparatus as may be required to work into each other.

In the new wiring scheme, these resistance lamps form part of the set at the multiplex tables, an arrangement that makes it impracticable for any of these sets to repeat into other sets that may happen to be differently wired, and vice versa.

In order to obviate this difficulty and bring about a more uniform system of local wiring, it will be necessary at those offices, which are, or may be equipped with the new quad apparatus, to effect such changes in the old style wiring as will make it conform with the new standard arrangement shown in Fig. 4.

Determining the Condition of Storage Batteries.—For determining the condition or degree of charge for a storage battery the voltmeter alone is not a reliable instrument; it is indispensable in the switchboard operations, and will surely indicate abnormal and accidental conditions, but cannot readily detect variations and slight defects in individual cells. If the battery is a fairly constant potential device, the voltmeter cannot be expected to find considerable or even readable variations in potential. The case is like that of a high water-tank or reservoir; this, too, is for maintaining a constant pressure, and an ordinary dial gauge could not be depended upon to give a reliable indication as to whether the reservoir was almost full or almost empty. If, suddenly, the gauge indicated zero, the tank would be known to be empty, but that condition is of course to be avoided. A gauge floating on the water is a simple and reliable device, so the hydrometer floating in the battery acid is found to give a safe indication of the condition of the plates. In large plants daily observations are taken of every cell, and recorded on a chart. Water is added to replace that lost by evaporation or decomposition, and acid to replace that lost by spraying. If a cell shows an unexpected diminution in specific gravity, a fault is at once suspected and, if possible, it is located and removed.

Any book published on electrical subjects can be obtained of Telegraph And Telephone Age, 253 Broadway, New York.

Report of Committee on High Tension Wire Crossings.*

(*Continued from page* 505.)

31. The poles, or towers, shall also be designed to withstand the loads specified in paragraph No. 30, combined with the unbalanced tension of:

2 broken wires for poles, or towers, carrying 5 wires or less.

3 broken wires for poles, or towers, carrying 6 to 10 wires.

4 broken wires for poles, or towers, carrying 11 or more wires.

32. Crossarms shall be designed to withstand the loading specified in paragraph No. 30, combined with the unbalanced tension of one wire broken at the pin farthest from the pole.

33. The poles, or towers, may be permitted a reasonable deflection under the specified loading, provided that such deflection does not reduce the clearances specified in paragraph No. 10 more than 25% or produce stresses in excess of those specified in paragraphs Nos. 65 to 69.

FACTORS OF SAFETY.

34. The ultimate unit stress divided by the allowable unit stress shall not be less than the following:

Wires and cables	2
Pins	2
Insulators, conductor attachments, guys	3
Wooden poles and crossarms	6
Structural steel	3
Reinforced concrete poles and crossarms	4
Foundations	2

NOTE.—The use of treated wooden poles and crossarms is recommended. The treatment of wooden poles and crossarms should be by thorough impregnation with preservatives by either closed or open-tank process. For poles, except in the case of yellow pine, the treatment need not extend higher than a point two feet above the ground line.

35. INSULATORS: Insulators for line voltages of less than 9,000 shall not flash over at four times the normal working voltage, under a precipitation of water of one-fifth of an inch (1-5") per minute, at an inclination of 45 degrees to the axis of the insulator.

36. Each separate part of a built-up insulator, for line voltages over 9,000, shall be subjected to the dry flash-over test of that part for five (5) consecutive minutes.

37. Each assembled and cemented insulator shall be subjected to its dry flash-over test for five (5) consecutive minutes.

The dry flash-over test shall be not less than:

Line Voltage.		Test Voltage.
Exceeding 9,000	but not exceeding 14,000.	65,000
Exceeding 14,000	but not exceeding 27,000.	100,000
Exceeding 27,000	but not exceeding 35,000.	125,000
Exceeding 35,000	but not exceeding 47,000.	150,000
Exceeding 47,000	but not exceeding 60,000.	180,000
Exceeding 60,000		3 times line voltage

38. Each insulator shall further be so designed that, with excessive potential, failure will first occur by flash-over and not by puncture. Each assembled insulator shall be subjected to a wet flash-over test, under a precipitation of water of one-fifth of an inch (1-5") per minute, at an inclination of forty-five degrees (45°) to the axis of the insulator.

The wet flash-over test shall be not less than:

Line Voltage.		Test Voltage.
Exceeding 9,000	but not exceeding 14,000.	40,000
Exceeding 14,000	but not exceeding 27,000.	60,000
Exceeding 27,000	but not exceeding 35,000.	80,000
Exceeding 35,000	but not exceeding 47,000.	100,000
Exceeding 47,000	but not exceeding 60,000.	120,000
Exceeding 60,000		Twice the line voltage

39. Test voltages above 35,000 volts shall be determined by the A. I. E. E. Standard Spark-Gap Method.

40. Test voltages below 35,000 volts shall be determined by transformer ratio.

MATERIAL.

41. CONDUCTORS: The conductors shall be of copper, aluminum, or other non-corrodible material, except that in exceptionally long spans, where the required mechanical strength cannot be obtained with the above materials, galvanized or copper covered steel strand may be used.

42. For voltages not exceeding 750 volts, solid or stranded conductors may be used up to and including 4/0 in size; above 4/0 in size, stranded conductors shall be used. For voltages exceeding 750 volts, and not exceeding 5,000 volts, solid or stranded conductors may be used up to and including 2/0 in size; above 2/0 in size, conductors shall be stranded. For voltages exceeding 5,000 volts, all conductors shall be stranded. Aluminum conductors for all voltages and sizes shall be stranded.

The minimum size of conductors shall be as follows:

No. 6 B. & S. gauge copper for voltages not exceeding 5000 volts.

No. 4 B. & S. gauge copper for voltages exceeding 5000 volts.

No. 1 B. & S. gauge aluminum for all voltages.

43. INSULATORS: Insulators shall be of porcelain for voltages exceeding 5000 volts.

44. Strain insulators for guys shall have an ultimate strength of not less than twice that of the guy in which placed. Strain insulators shall be so constructed that the guy wires holding the insulator in position will interlock in case of the failure of the insulator.

Strain insulators for guys shall not flash over at four times the maximum line voltage under a precipitation of water of one-fifth of an inch (1-5") per minute, at an inclination of forty-five degrees (45°) to the axis of the insulator.

45. PINS: For voltages of 5,000 and over, insulator pins shall be of steel, wrought iron, malleable iron, or other approved metal or alloy, and shall be galvanized, or otherwise protected from corrosion.

46. GUYS: Guys shall be galvanized or copper covered, stranded steel cable, not less than 5-16 inch

*Presented at the Boston Convention of the Association of Railway Telegraph Superintendents, June 26-30.

Digitized by Google

in diameter, of galvanized rolled rods of equivalent tensile strength.

47. Guys to the ground shall connect to a galvanized anchor rod, extending at least one foot above the ground level.

48. The detail of the anchorage shall be definitely shown upon the plans.

49. WOODEN POLES: Wooden poles shall be of selected timber, peeled, free from defects which would decrease their strength or durability, not less than seven (7) inches minimum diameter at the top, and meeting the requirements as specified in paragraphs 17, 30, 31 and 34.

50. CONCRETE: All concrete and concrete material shall be in accordance with the requirements of the Report of the Joint Committee on Concrete and Reinforced Concrete.

STRUCTURAL STEEL.

51. Structural steel shall be in accordance with the Manufacturers' Standard Specifications.

52. The design and workmanship shall be strictly in accordance with first-class practice.

53. The form of the frame shall be such that the stresses may be computed with reasonable accuracy, or the strength shall be determined by actual test.

54. The sections used shall permit inspection, cleaning and painting, and shall be free from pockets in which water or dirt can collect.

55. The length of a main compression member shall not exceed 180 times its radius of gyration. The length of a secondary compression member shall not exceed 220 times its least radius of gyration.

56. The minimum thickness of metal in galvanized structures shall be one-quarter inch (¼") for main members and one-eighth inch (⅛") for secondary members. The minimum thickness of painted material shall be one-quarter inch (¼").

PROTECTIVE COATING.

57. All structural steel shall be thoroughly cleaned at the shop and be galvanized, or given one coat of approved paint.

58. PAINTED MATERIAL: All contact surfaces shall be given one (1) coat of paint before assembling.

All painted structural steel shall be given two (2) field coats of an approved paint.

The surface of the metal shall be thoroughly cleaned of all dirt, grease, scale, etc., before painting, and no painting shall be done in freezing or rainy weather.

59. GALVANIZED MATERIAL: Galvanized material shall be in accordance with the Specifications for Galvanizing Iron and Steel. (Appendix.)

Bolt holes in galvanized material shall be made before galvanizing.

FOUNDATIONS.

60. The foundations for steel poles and towers shall be designed to prevent overturning.

The weight of concrete shall be assumed as 140 pounds per cubic foot. In good ground, the weight of "earth" (calculated at 30 degrees from the vertical) shall be assumed as 100 pounds per cubic foot. In swampy ground, special measures shall be taken to prevent uplift or depression.

61. The top of the concrete foundation, or casting, shall be not less than six inches (6") above the surface of the ground, or not less than one foot (1') above extreme high water.

62. When located in swampy ground, wooden crossing and next adjoining poles shall be set in barrels of broken stone or gravel, or in broken stone or timber footings.

63. When located in the sides of banks, or when subject to washouts, foundations shall be given additional depth, or be protected by cribbing or riprap.

64. All foundations and pole settings shall be tamped in six inch (6") layers, while back filling.

WORKING UNIT STRESSES.

Obtained by dividing the ultimate breaking strength by the factors of safety given in paragraph No. 34.

65. STRUCTURAL STEEL:

	Lbs. per sq. in.
Tension (net section)	18,000
Shear	14,000
Compression	18,000-60x

66. RIVETS, PINS:

	Lbs. per sq. in.
Shear	10,000
Bearing	20,000
Bending	20,000

67. BOLTS:

	Lbs. per sq. in.
Shear	8,500
Bearing	17,000
Bending	17,000

68. WIRES AND CABLES:

	Lbs. per sq. in.
Copper, hard drawn, solid, B. & S.—	
Gauge 4/0, 3/0, 2/0	25,000
Gauge 1/0	27,500
Gauge No. 1	28,500
Gauge Nos. 2, 4, 6	30,000
Copper, soft drawn, solid, B. & S.	17,000
Copper, hard drawn, stranded, B. & S.	30,000
Copper, soft drawn, stranded, B. & S.	17,000
Aluminum, hard drawn, stranded, B. & S.—	
Gauge under 4-0	12,000
Gauge 4-0 and over	11,500

69. UNTREATED TIMBER:

	Bending lbs. per sq. in.	Compression.
Eastern White Cedar	600	600 $(1-\frac{L}{60D})$
Chestnut	850	850 "
Washington Cedar	850	850 "
Idaho Cedar	850	850 "
Port Orford Cedar	1150	1150 "
Long Leaf Yellow Pine	1100	1100 "
Short Leaf Yellow Pine	950	950 "
Douglas Fir	1000	1000 "
White Oak	950	950 "
Red Cedar	700	700 "
Bald Cypress (Heartwood)	800	800 "
Redwood	850	850 "
Catalpa	500	500 "
Juniper	550	550 "

L=Length in inches.
D=Least side, or diameter, in inches.

The specifications are followed by five appendices giving tabulated information relating to wind and ice loads; conductor sags; specification for galvanizing for iron and steel; pole formulas and drawings of typical crossings.

QUESTIONS TO BE ANSWERED.

[We are daily receiving letters of commendation upon our plan of publishing lists of questions covering chapters in Jones' Diagrams. Students of telegraphy throughout the country are finding these questions of great assistance in their attempts to master the general principles underlying the operation of the apparatus with which they come in daily contact. Many consider this the best plan which has yet been devised for a systematic study of the technical side of the telegraph. We will continue to print similar lists of questions until we have covered all of Jones' Diagrams in this way. We will then take up Maver and Davis' "Quadruplex" and other standard works of telegraphy and treat them in the same manner.]

CHAPTER VII.

What are the conditions of operation of the Stearns duplex?

In working the Stearns duplex what is the effect upon the line of alternately connecting and disconnecting the battery?

Would the polar duplex work if the battery were alternately connected and disconnected?

What must be done in order to insure the operation of the polar duplex?

Why is it necessary, in order to obtain a quadruplex, to combine the Stearns and polar duplexes?

How is the polar relay actuated?

How is the neutral relay actuated?

If the polarity of the battery is reversed what is the effect of the reversal upon the neutral relay?

If the battery is increased in strength what is the effect upon the neutral relay?

In a quadruplex how are the poles of the battery reversed with respect to the line?

How is the strength of the battery increased and decreased?

If, when the battery is delivering its full strength to the line, the poles be reversed, what is the effect upon the polar relay?

Give the names of the instruments employed to reverse the battery and increase and decrease the current therefrom?

What is the function of the transmitter?

What is the function of the pole changer?

Does the current from the smaller portion of the distant battery have any effect upon the home neutral relay?

Which of the two relays is the more sensitive in practical operation, the neutral or the polar?

What are the characteristics of the magnets of the neutral relay?

What is the usual resistance of each coil of the polar relay, and what is that of each coil of the neutral relay?

Study Figs. 27 and 28 in order to understand how the transmitter changes the strength of the current on the wire.

What is the name of the combination of apparatus shown in Fig. 29?

When the polarity of the home battery is reversed, what is the effect upon the home instruments?

Why is a condenser inserted in the balancing wire between the rheostats and the relays?

What is the practical effect of the condenser discharge?

On long lines what is necessary to be done in order to retard the condenser discharge?

Why is it necessary to retard condenser discharges on long lines?

When the larger portion of the home battery is disconnected from the line by the operation of the transmitter, how is the internal resistance compensated for?

What is the effect of reversing the home battery of full strength upon the distant neutral relay?

How is the "clipping" of signals obviated?

What are the common designations for the polar and neutral sides of the quadruplex?

How Mr. Carnegie Spends His Time and His Money.

One of our subscribers wants to know how Mr. Andrew Carnegie spends his money and whether he is as good an operator now as he was in the "fifties" when he worked for the Pennsylvania Railroad Company, at Pittsburg. Many persons who are not in the millionaire class have more or less fantastic notions as to what real millionaires do to pass away the time and Mr. Carnegie is naturally the subject of much speculation. A story has gained circulation among operators that when he travels on land he invariably visits the telegraph offices in railroad stations and assists the overworked operator to receive a few train orders, while it is thought by others who would like to have a few of his millions that when Mr. Carnegie is at sea he puts in an occasional trick at the wireless.

It is stated that as he was walking down street one day he was stopped three times in each block by people who wished him to aid them financially. One minister wanted a new bellows for his church organ and he got them by the proper use of his own bellows.

Coronation Telegrams.—Press telegrams dispatched from London to the provinces and foreign countries on Coronation Day amounted to 847,000 words. On the following day, that of the Royal Progress, 370,000 words were dispatched. Both foreign and provincial messages shared in the increase, which has to be compared with an average daily total of from 150,000 to 200,000.

Telephone Economy in Railway Service.*

BY G. K. HEYER, OF NEW YORK.

There are few, if any, recent developments in the railway field which in so short a time have created such a widespread interest as that of telephone train dispatching.

The telegraph coming into the railway service as it did in 1850 through the foresight of Superintendent Charles Minot of the Erie Railroad made possible the abolition of the old time interval and flag system of advancing trains and the adoption of the present telegraph dispatching system, which it was thought for many years possessed sufficient advantages to allow the other branches of our railroads to be developed to the greatest possible efficiency. In spite of the improvements obtained by the telegraph, the first engineer who received a telegraph train order refused to run on it, believing that the risk attending such action was altogether too great.

In the search for increased efficiency in the telegraph department, the telephone, thirty-one years after its invention, was turned to as offering the greatest possibilities. The one disadvantage of the telephone was that the requirements for commercial service have been such that there was little or no demand for a means of selectively calling any one station on a long and heavily loaded line. This disadvantage went the way of all others which stand in the way of progress, and there are at the present time several selective devices on the market which to a greater or lesser degree of efficiency answer the requirements. The standard telephone equipment and practice were also found in some features to be inadequate and there have been developed special circuits and apparatus which have greatly improved the service and increased the flexibility and efficiency of the telephone system.

The maximum efficiency of the telephone system has not, however, by any means been reached, and there are under development and study at the present time many improvements, which indicate that there are no requirements for special service within the range of reason which cannot be met.

The advantages in favor of the telephone are that it is more flexible, quicker, safer and more reliable, and in addition makes possible better discipline and co-operation, as well as providing means for officials who are not familiar with the Morse code to exercise supervision and obtain immediate and accurate information in cases of emergency. The first installations made in the Fall of 1907 were so successful that there are to-day in the United States and Canada approximately 48,000 miles of line, or nearly 20 per cent. of the total railroad mileage equipped for telephone train dispatching, and the results obtained in every case sustain the judgment of the early advocates of the telephone.

Upon investigation in these days of scientific management, efficiency methods, etc., there stands out alone, far more important than any of the other advantages mentioned, although dependent in a great measure upon them, that of economy or the saving in dollars and cents which may be obtained by the use of the telephone.

Some of the factors which increase the traffic capacity and therefore make for economy in the telephone method of operation are:

1st. The time of calling stations, sending orders and receiving train reports is so greatly reduced (30 to 50 per cent.) that the time gained is available for the dispatcher in better laying out his work, planning meeting points and handling the endless amount of detail which the position requires.

2nd. Dispatchers are more efficient, due to the fact that they are relieved of the mental and physical strain attending the continual operation of the Morse key, which has a most damaging effect on the nervous system and frequently results in what is known as operator's paralysis.

3rd. Through the use of the portable and siding sets train crews may get into communication with the dispatcher and receive their advance orders directly from him. This has proven a most valuable branch of the service, especially in advancing freight trains which have taken a siding some distance from a station or tower. Also, during the night, when on some roads part of the stations are closed. In this latter case the train conductors may be provided with keys and in that way have access to the dispatching telephone.

4th. The dispatch and exactness with which reports of progress on clearing up wrecks and repairing breakdowns is given to the dispatcher, thus allowing him to determine as to the handling of other trains, routing them over other roads, etc.

It has been estimated by some of the roads that if, from a wreck or any other cause, traffic is held up, the additional expense incident thereto amounts to approximately $1,000 per hour. On the average, with the telephone system, wrecks are cleared up and traffic moving again in one-half to two-thirds of the time that is possible with the telegraph. A considerable saving, therefore, can be effected in these features of railroading, and approximate yearly figures may be arrived at by knowing the cost of suspended traffic and multiplying this together with one-third or one-half of the average time of clearing wrecks and the number of wrecks per year.

It may seem strange to many, particularly those who have not yet installed telephone equipment, to hear that such a saving is possible. Of course, the nature of the equipment is such that the initial cost of telephone apparatus is much higher than that of the telegraph equipment. Further, the cost of maintenance is also considerably greater with the telephone. The saving, therefore, does not show on the books of the telegraph department, and in fact, this department shows a somewhat increased running expense. This increase is, however, insignificant when compared to the reduction in the cost of handling traffic. The traffic or transportation department is then the place to look for the real

*Paper read at the Boston convention of the Association of Railway Telegraph Superintendents, June 26-30. Slightly abridged.

Digitized by Google

excuse for the expense of providing the telephone system.

The difficulty and expense incidental to securing from the records kept at the present time information from which may be computed reliable figures of comparative expense has undoubtedly delayed the preparation of such statistics. Mr. W. F. Williams of the Seaboard Air Line has, however, prepared information which shows that for one month on 150 miles of single track on his road, and with a 14.4 per cent. greater density of traffic for 1910 when the telephone was used, an average saving of one hour and twenty-six minutes in the running time of all through freights was effected over the same period for 1908 with the telegraph. This is a saving in time of 10.9 per cent. and it will be seen instantly by computing the pay of the train crews, reduction of overtime charges, increased efficiency of the motive power, the reduction in fuel consumption, the increased speed of hauling perishable freight, etc., that on any road the telephone is a good investment.

It is not possible to give a general figure representing in dollars and cents the value of the time saved, on account of the conditions surrounding the various railway systems. If, however, the items as given are reduced to a monetary value on the individual system, the results obtained will be greatly surprising, and in the case referred to would represent approximately from $1,000 to $1,500 per month, or a yearly saving of at least $12,000. Comparing the cost on the telephone equipment based on $100 per mile, (which includes the cost of telephone and selector apparatus, line wire—No. 9 B. & S. 208 lbs. to the mile—and installation) to the yearly saving in handling through freight traffic alone, it will be seen that the telephone will pay for itself the first year. In other terms, the yearly saving amounts to in the neighborhood of $100 per mile. Carrying this still further, we may say that for the 48,000 miles equipped there should be a difference in operating expense of approximately $4,800,000.

From information received from various sources, it is evident that on all roads hauling any considerable amount of through freight that the time consumed has been reduced since the installation of telephone equipment to compare very favorably with that shown on the Seaboard. For instance, on the Delaware, Lackawanna & Western Railroad, after the completion of the service between Binghampton and Buffalo, a distance of 206 miles, with 46 stations, the through freights were run in approximately two hours less than was the rule when the dispatching was done by telegraph.

With the great increase in the number of telephones for commercial service and the consequent economies effected, it is only to be expected that the use of the telephone for railway service will gradually be extended to embrace many other branches. In fact this has already been done on some of the more progressive roads.

For handling message or other commercial and routine business between stations, the worth of the telephone has already been proven on several roads, and it is estimated that for this class of business one telephone circuit has the capacity of two telegraph circuits. On roads where the traffic is light, the dispatching and message work can be carried on over the same pair of wires.

In connection with manual blocking, the old telegraph wires may be utilized, thus providing a grounded block circuit, or, if convenient, a metallic circuit may be employed. Either the grounded or metallic circuit is far superior to the telegraph. Blocking sets or a switching mechanism may be provided to allow one set of telephone equipment to be used on the train, message and block wires, and to cut two blocks into one for night operation.

The loud speaking receiver is admirably adapted for this service and it is thought will ultimately replace the ordinary receiver for block work.

Another use for the loud speaking receiver is in the dispatcher's office, where it may be connected directly to the train wire and relieve the dispatcher of wearing the head receiver at least a part of the time.

The train order semaphore, one of the recent developments, which consists of a standard semaphore mast arranged for mounting the selector and telephone apparatus in a weather-proof compartment, can be placed at any point along the line and the telephone and selector connected directly to the train wire.

The Devil in Turkey.—Referring to the concession recently granted to an English syndicate for the installation of a telephone system in Constantinople, the *St. Martin's-Le-Grand*, of London, tells a humorous story in connection with the introduction of the telegraph in that country: "A full meeting of the Ulema debated it," the story goes on, "and declared it to be the invention of the devil. But a wise and ancient Mollah who presided, said, 'My children, the telegraph is a good thing.' 'What,' chorused the others, 'do you mean that it is not a work of the devil?' 'Oh, assuredly,' answered the president, 'assuredly it is a work of his; but why are you so dull of understanding, my children? Can you not see that if the devil is occupied going up and down the wires with each message sent, he will have less time to trouble us mortals on the earth below?' And so Turkey got her telegraph, and has to-day 49,200 miles of these devil's pathways gleaming over the heads of the faithful."

Business in Prospect.—A certain telegraph superintendent recently asked the manager in a small town why his monthly reports were delayed, whereupon the manager replied: "Sent none; received none; prospects good."

Sending Machines Cannot Retaliate.—An operator in a Western city wrote "ananvan" for 1141 and in order to find an excuse for it blamed the sending machine.

Current Indicator for Morse Relays.

BY J. S. KNAPP, BUFFALO, N. Y.

So much trouble results from the breaking in on a wire during wet weather by inexperienced telegraphers while their relay is out of adjustment, that anything tending to relieve the situation is always welcome. The following simple remedy has been proven thoroughly effective in such cases and is offered for the benefit of the service.

Each relay should be equipped with a small compass, about the size of a ten-cent piece, imbedded in the top of the relay base, directly in front of the center of the armature and as close to the latter as possible without touching it. It is evident that when the line is open or closed, the compass needle will remain practically at rest, but as soon as signals are being made by any office on the line, it will turn upon its pivot with a quickness of motion depending upon the electromagnetic force exerted upon it.

After once being instructed, operators will naturally observe the tell-tale compass and the old wet weather bug-bear will be a thing of the past.

The Telephone Relay.

Numerous tests have been made in recent years in telephone practice, says *Zeit. f. Schwachstromtechnik,* to strengthen the sound transmitted by the wires. In spite of numerous patents and trials it has not been found possible to fulfill all conditions necessary in practical work for the desired ends. The two reasons which account for the failure in this direction are probably, first, that the fundamental tones of the relays were chosen too low, and, second, that the relays were not sensitive enough. Even the receivers, as also the microphone diaphragms, are deeper in tone than they really should be for best results. If the two parts of the apparatus are joined together in practice, the fundamentals are lowered still more, and the relay therefore strengthens the low tones, but weakens the higher ones, which are the ones that are absolutely necessary to the transmission of sound. Consequently the sound transmitted is in poor condition and unintelligible.

Another circumstance which impeded the exploitation of the telephone relay was the fact that it was only to be used to strengthen weak currents, and therefore it was only brought into the line at the ends of the electric current circuits. In long overhead lines, as, for example, in 1,000-km. lines, the stray currents are almost as strong as the telephone currents, and it can even happen that the stray currents have a higher tension than the telephone currents. As the frequency of these currents will always be lower than the telephone circuit frequency, the result is that the stronger currents are strengthened still more, resulting in a poor transmission of sound. To be successful the telephone relay must be placed in the circuit where the telephone currents are far superior to stray currents, which is done in most cases in present practice on long distance lines. It is probably impossible to construct a telephone relay which will meet all the requirements of the present type of microphones. However, it is possible with high tension microphones, even without relay, to speak over lines of several thousand kilometers length. If a telephone relay is placed in the circuit after the first 1,000 km., the effect can be improved considerably.

If, for example, the vowel "a" is spoken into the microphone, using a 1,300-km. line of 4 mm. bronze wire, and the relay is placed after the first 900 km., the receiving current at the end of the line will be 1,928 microamperes, where it would be only 212 microamperes without the relay.

If the same vowel is spoken into a microphone on a 1,700-km. line, and the relay placed again 900 km. from the transmitting microphone, the receiving current will be 848 microamperes, where it would have been 212 microamperes without the relay.

If under the same conditions the distance is 2,100 km. and the relay at 900 km. from the transmitter, the end current without the relay will be 50, with the relay 318 microamperes.

On a 2100-km. line under similar circumstances, the end current will be 318 microamperes, and when the relay is placed at a distance of 900 km. from the transmitting microphone it will be 7,845 microamperes. Just before the current reaches the relay it will be 1,060 microamperes. If the same vowel is spoken into the microphone of a 2,100-km. line, and a shunt is used, the relay will send a current of 7,000 microamperes into the line. The current just before the relay is 848 microamperes. The current at the beginning of the line is 1,225 microamperes.

Thousands of kilometres can be gained by a single relay placed at the right position in the circuit. In connection with these investigations microphones were used that could be cooled and had a construction similar to that of the ordinary long distance telephone microphones. A receiving apparatus with a lever resistance was also tried, and, of course, in this case the end current is larger. Further tests, in which the relation of the current received in the transmitter and that sent by the relay into the line was investigated, have shown that with a certain number of sound waves resonance sets in, which is also the case in microphone diaphragm. The best plan was thought to be the one of placing several relays in a telephone circuit, where one relay is calibrated to the number of vibrations most necessary to telephone conversation, namely, the vowel "a," of 900 periods, and then another relay which is tuned to a much higher number of vibrations. This did not work out in practice as anticipated, and no satisfactory results have been found out so far to meet this condition. There is no doubt, though, that a suitable relay which will meet all requirements will be constructed within a short time.

Telegraph Construction on the Canadian-Pacific Railway.*

BY E. A. LAKEY.

I had the good fortune to be sent out to Calgary (Alberta) in connection with the opening of the Pacific Cable Board's land line from Montreal to Vancouver. Calgary is 2,252 miles from Montreal on the Canadian-Pacific Railway, and naturally the Canadian-Pacific Railway telegraph construction came under my observation.

The line of poles is located, wherever possible, at least 30 ft. from the rail, and the poles are erected from forty to forty-four poles to the mile. Two kinds of cedar poles are used, but they are not "preserved" in any way. In the Eastern provinces the swamp cedar is utilized. These poles are rather short and crooked, and have an average life of about twenty-five years. In the West the poles are of mountain cedar. These are long and straight, and good poles can be obtained up to 120 ft. or so in length. The mountain cedar pole, however, does not last so well and has a life of about ten years on the sandy soil of the prairie. A peculiarity of their decay on the prairie is that the rot takes place from the butt of the pole upwards, and not at the ground line, owing to the action of the alkali in the ground.

Cross-arms are of fir. An arm for four wires, or a 4-pin arm, as it is termed in Canada, is 6 ft. long, and the 6-pin arm is 7½ ft. The top of the arms is 4 in. below the bottom of the roof of the pole, and they are fixed on the pole 2 ft. between centres, being fastened by two 6½ in. coach-screws. All 4-pin arms are braced with one iron brace, 28 in. x 1 in. x ¼ in., placed at an angle of 45°. The 6-pin arms have two braces, one on each side of the pole, and one coach-screw is used to fasten both braces to the pole. Braces are attached on the face of the pole and the face of the arm. Insulator pins are of oak and 9 in. long. The portion in the arm is 4 in. long and it is fastened by a nail.

The insulators are mostly glass, and they are of all shades of blue and green. I noticed some porcelain insulators. All cross-arms are fully equipped with pins when put up.

The top of a pole is made wedge-shaped, but no galvanized iron roof is fixed. Four inches of the pole are used for this purpose, so that the top of the first arm is eight inches from the apex of the pole. One or more extra slots or "gains" are cut on each pole in all new work, and where a side block or bracket line is built a flat surface is blazed on the pole at right angles to the gain, the bracket then being fastened to the pole with its top nail exactly opposite the top line of the gain. This allows an arm to be added without interfering with the bracket or the wire on it.

It is the practice to double-arm poles at each half mile to save the wires from running back in case of a breakdown. Double arms are also fixed on corner-poles and on the poles adjacent. It is also specified that the first pole from a corner must not be set to exceed 100 ft. from the corner-pole, and as much closer as necessity may require; which in all cases is to be determined by the weight of the line, and the side strain of the corner-pole.

Corner-poles are also to be located so that the wires will not turn at an angle of less than 157½°.

Poles are set up in such a way that the arms on the second pole on each side of a corner-pole are facing the corner-pole. In all other places poles are set up so that the arms are facing alternately. Stays are used in preference to struts, and longitudinal stays are fixed on every fifteenth pole in a long, straight line.

At most of the curves the poles are set with a very decided slant against the curve, but this was well graduated. The heights of the poles are also well graduated in uneven ground and at railway crossings. A clearance of about 12 ft. is given on high ground, and about 30 ft. is given at railway crossings.

Only every fifteenth pole is supposed to be earth wired by means of Nos. 8 or 9 galvanized iron wire for protective purposes. The earth wire extends from 3 in. above the top of the pole to within 1 ft. of the butt, where four spiral turns are made round the pole, and it is then continued to the bottom, where a coil of about 4 ft. is fastened. All terminal poles are equipped in this way.

Holes are generally dug round and 6 in. or so more in diameter than the pole to be erected. The tool in general use for this purpose is a digging bar of octagonal steel 1⅛ in. by 9 ft. Shovels and spoons for removing the soil have handles 9 ft. long. The butt of a pole is well keyed with stones, and great care is exercised in punning. Stones are heaped around the poles fixed on the prairie to prevent grass from growing, so that a prairie fire just sweeps past without damaging the line.

For erecting poles in quicksand a special caisson is used. This is made of ⅛ in. sheet iron, 3 ft. 6 in. long, and having a diameter of 1 ft. 6 in. It is hinged on one side with a bolt on the other side so that the caisson can be withdrawn when the pole is in position.

Mostly galvanized iron wire has been strung, but some of the latest wires are 210 lb. copper, and there is between Montreal and Vancouver, a distance of 2,898 miles, one of 300-lb. copper.

Iron wire is bound in by means of No. 8 galvanized iron wire 14 in. long This is placed around the insulator and each end is given four turns around the line wire. Copper wire is bound with a soft copper binder of the same gauge as the wire being strung. The binder is placed in the groove of the insulator and crossed on the line side. The line wire is then placed over this cross and the binding completed by giving four or more complete spiral turns using up each end

* Post Office Electrical Engineers' Journal.

Digitized by Google

of the binder. Sleeves are in general use for jointing copper wire.

Wires are bound in on the side of the insulators nearest the pole except at curves where it may be necessary to place the wire on the opposite side, so that the strain is against the insulator. The general practice for leading-in is by overhead cable from a pole test-box.

To reduce inductive disturbance the Pacific Cable Board's line is transposed every half mile between three poles. Three different methods of doing this are used:

(1) The wire was strung on the outer position of the third arm, and in transposing was raised to an additional insulator fixed on the second arm of the centre pole.

(2) A J-bolt was fixed under the second arm of the centre pole to carry the wire and insulator.

(3) The wire was strung on brackets, and at the centre pole took the outer position on the third arm.

After this brief resumé I will just mention the result of an insulation test I took from Calgary to Fort William on this line, a distance of 1,257 miles. On a differential galvanometer, the only means of testing available, and with 200 volts, there was absolutely no loss discernible. This test was taken in fine weather.

Outing of New York Staff of Commercial Cable Company.

Mr. Clarence H. Mackay tendered an outing to the members of the New York Staff of the Commercial Cable Company, on Sunday, July 23, at Witzel's Point View Island, L. I., N. Y. About 150 members of the staff left the Battery landing by the steamer *"Osprey"* and arrived at the grove at about 11.45 a. m. Breakfast was then partaken of and at the conclusion a baseball game was played between teams representing the Executive Office and 20 Broad Street office, respectively, which resulted in an easy victory for the Executive Office, the score being 15 to 3. Mr. Quinn, the pitcher for the Executive Office, pitched a masterful ball, and Broad Street was only able to get one hit off his delivery. A series of athletic events were then run off, consisting of a wheelbarrow race, a sack race, three-legged race, fat men's race, shoe race, and a relay race between the Executive Office and 20 Broad Street. The last event was the most exciting feature of the day, Broad Street finally winning the race by less than a foot. Very handsome and valuable prizes were awarded to the winners and second men in each of the events, and to each player on the winning ball team and to each runner on the winning relay team. A course dinner was served at 6.30 p. m. and a cablegram from Mr. Mackay, who is now on a tour of inspection of the European stations, was read, and was received with great enthusiasm. Upon the conclusion of the dinner the party boarded the steamer and returned to New York after an enjoyable day.

New Telegraph and Telephone Building in Buffalo.

In two or three months the New York Telephone Company will start the erection in Buffalo of a new building to be located at the southeast corner of Church and Franklin streets, which will be jointly occupied by that company and the Western Union Telegraph Company. The plans will provide for an ultimate "U" shaped building of fifteen stories, with a frontage of 184 feet on Franklin Street and 76 feet on Church Street. The building to be erected at present will be carried up fifteen stories on the corner and four stories in the rear. Additional space will be provided in the future by carrying up the rear of the building to the full height of fifteen stories.

The building will be of the steel skeleton type, fireproof construction throughout, and light glazed brick, terra cotta trim and granite base will be used for the exterior construction. The building when completed will cost approximately $700,000.

The local commercial and supply departments of the New York Telephone Company will occupy part of the first floor, the remainder being occupied by the Western Union, who will also take the entire second floor.

A switchboard with an ultimate capacity of 10,000 lines and an initial equipment of about 5,600 lines will be installed on the fourth floor. When the first switchboard reaches its capacity a second 10,000 line board will be installed on the sixth floor.

On the fifth floor will be located the terminal room, occupying with a men's room, the entire floor at present. The racks to which the underground and telephone switchboard cables are connected, the arresters which protect the telephone lines from lightning and stray currents, the power plant and storage batteries and all the other frames and racks necessary in connection with a modern telephone exchange, are located in this room.

The sixth, seventh and eleventh floors will not be occupied at present by the New York Telephone Company or allied companies and will probably be divided into offices and rented as such. The eighth floor will be occupied by the American Telephone & Telegraph Company, the ninth and tenth floors by the division auditor and force, the twelfth by the plant engineer, the thirteenth by the division plant department, the fourteenth by the traffic department and the fifteenth by the division commercial department.

English Telegraph System.—The London main telegraph office is stated to be the largest in the world. From it underground telegraph cables are laid to Scotland on the north and to the southernmost point of England, with similar underground trunks east and west. The post-office has now nearly 1,200,000 miles of wire, half for telephone, and nearly 750,000 miles of that aggregate is underground or submarine cables, proof against snow, sleet and wind.

KERITE

INSULATED WIRES and CABLES

DEPENDABLE

Kerite Cables installed upward of 35 years ago, and exposed to deteriorating influences, are giving perfect service to-day.

EFFICIENT

Kerite does not rely upon the rubber in its composition for insulating efficiency. Kerite itself is a compound having superior insulating qualities.

SERVICE

A half century of successful service has demonstrated that Kerite possesses the essential qualities of safety, reliability and economy to an exceptional degree.

Kerite Insulated Wire and Cable Co.

Selectively Operated Semaphore and Telephone Equipment.

Since the development of the telephone for train dispatching, a need has been felt for signaling equipment which could be used and operated in connection with a telephone train wire. That is, instead of having a selector on a telephone circuit ring a bell at a way station, it was required that it should throw a semaphore arm. The Western Electric Company, in conjunction with the Union Switch and Signal Company, has developed apparatus to meet this particular need.

Both steam and electric railroads offer an extensive field of use for this selectively operated semaphore in connection with the telephone system. On steam roads it will probably be used exclusively for train order work. In other words, it will be employed as an auxiliary to a regular telephone train dispatching system. When used in this way it will secure a still further saving than is now effected by the telephone.

FIG. 1.—SELECTIVELY OPERATED SEMAPHORE.

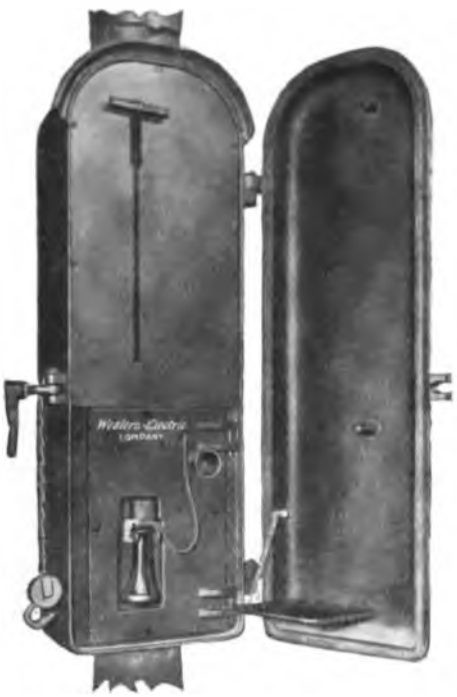

FIG. 2.—CASTING CONTAINING SIGNAL MECHANISM.

FIG. 3.—SELECTOR AND TERMINAL APPARATUS INSIDE OF CASTING.

The train order semaphore can be installed at any point desired along the right-of-way: the dispatcher can throw it at will just as he can call a way station. He is informed absolutely as to whether the selector which he threw operated, and when the train is stopped by this means he can get into direct touch with the train crew and give them their orders.

The semaphore can, in many places, be used as an auxiliary to the regular dispatching system, as it can be located at sidings or at points where the expense of a station and operators is not warranted. It thus forms a safeguard to the system that does not include the human factor. It can also, of course, be used in conjunction with way stations for this same purpose, permitting the dispatcher to throw a signal to "stop" if he, for any reason, cannot reach the operator he desires.

Sometimes when trains are cleared it is desired to stop them further on, such as at the entrance to a yard or at other points before they reach their next train order station. In all such cases the selectively operated semaphore forms a valuable adjunct to the train dispatching system.

In Fig. 1 is shown the outfit complete. The semaphore proper is of standard make and can be furnished in either the upper or lower quadrant types, as desired. A three-spectacle casting is provided. The semaphore, selector and telephone equipment are all mounted on the same iron post, and the apparatus is self-contained. All the telephone apparatus is water-proofed to withstand moisture. All wood used in the interior of the set is oil treated. The telephone and selector are enclosed in an inner compartment. All openings are arranged so that water cannot enter the set. In addition, the outer door of the set has a weatherproof gasket, rendering it practically impervious to moisture.

Fig. 2 shows the pole casting containing signal mechanism, the telephone and selector equipment. The signal mechanism is of the electrically operated type, but is manually restored. The relay operating this is normally de-energized, and ten dry cells are required for its operation. As

Digitized by Google

this relay will operate on four cells, it is obvious that an ample margin of operation is allowed. One important feature of the selectively operated semaphore is the fact that it gives to the dispatcher an answer-back which cannot be mistaken, telling him that one particular semaphore has completed its movement and is at the "Stop" position at the time the answer-back signal is received.

The telephone set is especially designed for railway work. The transmitter and receiver are mounted on the outside of the inner door, on the lower part of the apparatus casting. The signal mechanism is operated by the Western Electric's latest railway selectors.

Fig. 3 shows the arrangement of the selector and terminal apparatus on the inside of the casting.

The circuit arrangements of the signaling equipment are very similar to the company's standard train dispatching circuit. The dispatcher operates selector keys in the same manner; instead, however, of a bell ringing at the point called, a semaphore blade moves to "Stop." The answer-back signal returns to the dispatcher clearly and distinctly and then it waits for the crew of the train so signaled to call in.

Sandwich Electric Company.—At the recent Boston convention of the Association of Railway Telegraph Superintendents, the Sandwich Electric Company, of Sandwich, Ill., made an exhibit of its type 9 B selector, and No. 76 call-box such as is used in dispatcher's circuits and intercommunicating message circuits. One of the specialties shown was the cordless jack box. Another feature of the exhibit was the block office set, assembled in a compact form for use on a metallic block circuit, the two wires of which are automatically simplexed and can be used for a Morse message circuit, at the same time they are used for the telephone block. The exhibit was in charge of Mr. C. S. Rhoads, Jr., engineer of the company.

Extension of Telephone Train Dispatching on the Lehigh Valley Railroad.

The Lehigh Valley Railroad has just placed an order with the Western Electric Company for selector and telephone apparatus to equip the west end of the Buffalo division. The new circuit will be 135 miles in length and the dispatcher will be located at Buffalo. Upon the completion of the telephone circuits now under construction, traffic on the entire line from Jersey City to Buffalo and Suspension Bridge will be handled by the telephone.

Selective Signaling System.—The General Railway Signal Company, Rochester, N. Y., has issued a bulletin, No. 114-A, describing and illustrating its selective signaling system as used in telephone train dispatching. It is a neatly designed and executed pamphlet and the subject is presented in an attractive manner.

ANSWERS TO QUESTIONS.

[In this department questions on matters of a practical character, and of general interest, will be answered. Questions intended for this department must be signed by the writer's full name—not for publication, but for identity. No attention will be paid to anonymous communications.]

(53) Q. What is the usual cause of the failure of a selective calling instrument to operate? I. O.

A. It is generally due to either a weak main battery or a weak local battery. All batteries should be inspected and tested at regular intervals. Repeated false calls are indications of weak main battery or improper signal relay adjustment.

(54) Q. In measuring the voltage of dry cells is it advisable to take the measurement with the current flowing? What is the lowest permissible voltage of a cell? V. M.

A. Yes. When cells tested under load show less than 0.7 volt they should be renewed.

(55) Q. What is the required insulation of condensers used in duplex and quadruplex telegraphy? C. A. I.

A. About 40 megohms per microfarad after a charge of one minute duration.

(56) Q. How much current is necessary for the proper operation of a 150-ohm relay, and how much for the polar and neutral relays of a quadruplex? R.

A. About forty milliamperes for a Morse 150-ohm relay; about twenty-five milliamperes for a polar relay and about seventy milliamperes for the neutral relay.

(57) Q. What book can you recommend as covering the entire subject of telegraphy in theory and practice? C. Y. R.

A. Maver's "American Telegraphy and Encyclopedia of the Telegraph," is the standard work on telegraphy in this country. The price is $5.00 per copy. Copies can be obtained at the office of TELEGRAPH AND TELEPHONE AGE.

(58) Q. Please give me some information regarding German silver wire; what are its constituents, unit weight, specific gravity, etc. T. T.

A. German silver is an alloy consisting of 18 per cent. to 30 per cent. nickel and the remainder about 4 parts copper to 1 part zinc. The weight of the alloy per cubic foot is about 530 lb.; specific gravity, 8.5. The resistance of the 18 per cent. alloy at 25° C. is 18 times that of copper, and of the 30 per cent. alloy about 28 times that of copper. The maximum safe carrying capacity of German-silver wire in spirals in open air for continuous duty is such that the circular mils per ampere vary from about 1,500 in No. 10 wire to about 475 in No. 30. For intermittent duty, the capacity is twice as great.

(59) Q. What kind of wire is generally used for telephone train dispatching and message circuits? F. C. M.

A. Hard drawn copper No. 9 B. & S. gauge, weight 209 lbs. per mile and with a resistance of 4.186 ohms per mile.

Listening Set and Foot Switch for Telephone Train Dispatching Circuits.

A sole leather listening outfit for telephone train dispatching circuits has been put upon the market by the Western Electric Company. This device is so small that it can be very easily carried in the pocket. It consists of a receiver, condenser and the necessary cords and clips for attaching it to the line. With this instrument, which is illustrated in Fig. 1, it is possible for an official to

FIG. 1.—LISTENING SET.

connect the receiver to the line at any station where he may happen to be, without interfering with the regular operator and without anyone knowing that he has cut in on the circuit.

Fig. 2 shows a foot switch which has been designed by the same company for use on telephone train dispatching circuits having any number of telephone sets up to 60 or 70. For conditions like this where it is possible for any number of these

FIG. 2.—FOOT SWITCH.

stations to be listening in upon the circuit simultaneously and where quite frequently from four to six stations are called in to receive orders, this apparatus has been especially designed. The switch consists merely of a cast iron case in which the switch springs are mounted and from which a lever projects to operate the springs by foot power. It permits of greater speed in the use of telephone apparatus. For this reason it is largely used in connection with the special types of telephone arms with which an operator does not have to put on any head set nor touch a receiver. These arms were especially designed for use in interlocking towers where the operator is obliged to get away from the telephone quickly in order to handle the switch levers.

New Telephone Circuits for Chicago and Northwestern.

The Chicago and Northwestern Railroad Company which has been using the telephone for dispatching trains on several of its divisions for some time past, has just placed an order with the Western Electric Company for telephone selectors to equip five new circuits. The number of selectors used on these circuits will be 130 and the length of circuits will be over six hundred miles.

The circuits to be equipped are on the Fremont division, two on the East Iowa division and two on the Dakota division. The Fremont circuit will be equipped with 21 stations, and will run between Fremont, Missouri Valley, Omaha and South Omaha. The East Iowa division is divided into two circuits, the dispatcher for each being located at Belle Plain, Iowa. One circuit extends from Belle Plain to South Clinton, a distance of 116 miles, and is equipped with 31 selectors; the other extends from Belle Plain to Boone, Iowa, a distance of 87 miles, and is equipped with 23 selectors. One of the Dakota circuits will run from Huron to Brookins, with branch lines from Athol to Oakes and from Turton to Croton, the distance covered by this main circuit and branches being 170 miles. The dispatcher will be located at Huron, and the circuit will be equipped with 36 stations. The second Dakota circuit will run from Huron to Tracy, a distance of 163 miles. This circuit will be equipped with 20 stations and the dispatcher will be located at Huron.

Telephone Apparatus.—The Kellogg Switchboard and Supply Company, Chicago, Ill., has issued a very complete bulletin of the apparatus manufactured by it. It is a new and unique catalogue and covers all the important items in standard telephone work. Each item is illustrated, coded and briefly described. A telephone man wishing to buy anything from binding posts to pole changers, or dry cells to a twenty-thousand line exchange can find the important specifications in this catalogue in a moment's notice by referring to the comprehensive index.

Suggested Rules for Telephone Train Dispatching.—In Bulletin No. 502 issued by the United States Electric Company, New York, are given suggested rules for telephone train dispatching. This subject was made the basis of an interesting article in our issue for June 16, by Mr. J. W. Barney. These rules are indicative of approved practice, but are not mandatory in any sense of the word.

Annual Outing of French Telegraph Cable Company's Employes.

The fifth annual outing of the French Telegraph Cable Company's employes in New York was held on July 2, at College Point, L. I., N. Y. The company chartered a steamer upon which the employes were taken on a trip up the Sound and along the Connecticut shore as far as Stamford, returning to College Point, where the rest of the day was spent. During the afternoon various sports were indulged in and a game of baseball between a team composed of operators and clerks and one made up from the messenger staff was won by the clerks with a score of 17 to 5. After the ball game various foot races were run, and at 6 p. m. an excellent dinner was served.

Mr. E. C. Sweeney, traffic manager, New York, was honorary president of the day, and among the other guests were: Messrs. G. Godfroy, C. Sutton, C. Striffling, D. Callaghan, J. Wiseman, J. Coghlan, G. Jenkins, M. Porter, J. Kernan, B. Jordan, J. G. Sherry, and K. Lutz.

T. M. B. A. Assessment.—Assessment No. 527 has been levied by the Telegraphers Mutual Benefit Association to meet claims arising from the deaths of Thomas P. Scully at Brooklyn, N. Y.; Emily C. Ormsby at Canandaigua, N. Y.; Robert S. Haynie at Kansas City, Mo.; Jesse H. Robinson at Washington, D. C.; Frank J. Brown at Detroit, Mich.; George Heitz at Vincennes, Ind.; Teresa J. Bunnell at New York, N. Y.; Cyrus Cole at Jersey City, N. J.; William F. Burton at Nashville, Tenn.; Samuel J. Dennis at Arlington, N. J.; De Witt Bander at Hammondsport, N. Y.; George F. Lehmer at Omaha, Neb.

LETTERS FROM OUR AGENTS.

PHILADELPHIA, POSTAL.

Harry Medway and John J. McLaughlin, of the clerical department, died recently. Both men were in the prime of life and had many friends in this office.

Chief Operator E. W. Miller has returned to his desk after a stay in the country, looking very much refreshed.

Mr. Morris Ruberg, of the American Telephone and Telegraph Company, was a recent visitor.

PHILADELPHIA, WESTERN UNION.

Mr. Frank E. Maize, manager of the Electric Bureau, is spending a two weeks' vacation at Wildwood, N. J.

Miss Fannie Schott has returned from a ten days' vacation spent at Wildwood, N. J.

Miss Nannie Hall is spending a vacation at the Delaware Water Gap, Pa.

SAN FRANCISCO, WESTERN UNION.

Mr. A. C. Parsons, formerly night chief at San Francisco, has been transferred to Los Angeles as chief operator vice Mr. S. J. Gray, who is now at Vancouver, engaged in special work for the company.

The main operating room is being fitted up with new tables and new equipment, filling in the space formerly occupied by the old switch board and dynamos. The board has been moved to the new quad. room on the third floor. The staff in the quad. room consists of Messrs. W. H. Wilson, T. Crow, S. Mills, T. Gilbert, J. L. Lowrey, C. H. Warrensford and T. H. Hooper.

The great telegraphic song hit, "SEND ME A NIGHT LETTER, DEARIE." Good, catchy music; beautiful title design magnificently printed in colors. Title contains night letter. Sung all over New York, 17c. by mail. All popular music sent by mail.

B. L. BRANNAN,
195 B'way, N. Y.

FOR SALE—A Bunnell galvanometer, complete in leather case, with resistance coils and connections for Wheatstone bridge measurements. Must be disposed of immediately to close an estate. Cost over $100.00. Will sell for $35.00. Address "Galvanometer," care Telegraph and Telephone Age, New York.

Life Insurance is based upon the certainty of death at some time and its possibility at any time. The splendid financial position of the Telegraphers' Mutual Benefit Association, 195 Broadway, New York, is shown in the Reserve Fund, of $327,000, which, apart from current assets, amounts to nearly 6½% of the total contingent mortuary liabilities, and yields an annual revenue of more than $15,000; operating on sound and correct principles, with ample security, it offers to the telegraph and telephone employe the best and most economical form of protection for the family and dependents yet devised. Write for particulars.

TRANSMITTING MACHINES

I am placing on the market improved YETMAN TRANSMITTING TYPEWRITERS, and KEYBOARD TRANSMITTERS without typewriting features. Am prepared to exchange, repair or rebuild all old machines. Write for catalogues and particulars to

James Uncles, NORTH ADAMS Massachusetts

Rubber Telegraph Key Knobs.

No operator who has had to use a hard key knob continuously should fail to possess one of these flexible rubber key caps, which fits snugly over the hard rubber key knob, forming an air cushion. They render the touch smooth and the manipulation of the key much easier. Price, fifteen cents.

J. B. Taltavall, TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

Every one engaged in telegraphy and telephony should be a constant reader of TELEGRAPH AND TELEPHONE AGE. It gives the latest news in both these fields. Subscribe now. Subscription price, $2.00 per year.

SOME POINTS ON ELECTRICITY.

BY WILLIS H. JONES.

Electrical Wire Connections for Automobile Gasolene Motors.

A correspondent writes as follows:

"Now that quite a number of operators and others in the telegraph service have risen to the dignity of owning an automobile, will you kindly give us some information concerning the manner in which the battery and electrical connections for gasolene motors are made and the principle of operation? If to this you can add any other information or advice that may be useful, I think you will find many eager readers."

While the writer of this column does not claim to be an expert on the automobile and its operation, he will endeavor to reply to the inquiry by imparting such information as he personally gained while cutting a large wisdom tooth during his first season's experiment with a touring car.

We will begin with the "other information" requested.

Probably the best advice the writer can offer to a novice who contemplates the purchase and personal operation of a car is that unless he possesses a pretty substantial reserve bank account, is "DON'T." At least he should postpone the personal operation of the machine until he has studied the proposition carefully and thoroughly understands its construction, as well as learned the pitfalls to avoid.

The fact has been pretty well established that the ignorance of certain necessary preliminary facts usually costs the majority of novices between $100 and $200 the first season, nearly all of which expense might have been avoided had they learned the ropes before instead of "after taking."

For the inexperienced it makes but little difference whether the car is new or second-hand; the result will be practically the same. His expense account is usually due to ignorance of the following facts:

LOOSE BOLTS AND NUTS.

The vibrations caused by the motion of the car soon loosens the nuts and bolts. When this occurs, even though one may escape an accident, the thread and other parts not only wear down quickly and require renewal, but such defects often first throw other parts of the machinery out of gear and cause serious trouble. Thus a loose nut may cause a fore wheel to be put out of alignment with the rear wheels. When this happens, the result is disastrous to the tires.

TIRE TROUBLE.

When a wheel wabbles or is out of alignment the tire is dragged over the ground for several inches during each revolution just as if it were locked for the time being. The result is that the rubber is soon either split open all around the periphery or worn down to the canvas. The weakened shoe is then unable to protect the inner tube properly and a "blow-out" soon follows. Other blow-outs obviously follow in quick order, after which both shoe and tube become unsafe and practically useless.

MISTAKEN ECONOMY.

When a novice is first confronted with the necessity of purchasing new tires he usually makes the mistake of buying a "second" or an inferior grade on account of its somewhat lower price. They all look alike to him.

The lesson he learns by pursuing this course is that the cheaper grades possess neither the quantity of rubber nor the strength to withstand a grind or temporary strain long enough for him to locate the trouble and remedy it. A first class shoe, however, gives ample time for investigation without being appreciably affected. It costs, probably, 15 or 20 per cent. more than the inferior kind, but will last three times as long. By the time two or three cheap tires have been worn out and as many inner tubes have been ruined he has learned that one high grade shoe costs much less in the end and gives better service in every way.

Digitized by Google

LUBRICATING OIL.

The same rule applies to the quality and quantity of lubricating oil used. The better the grade and more of it used, within reasonable limits, the less expense one will incur. Oil, of course, is expensive, but it is very cheap indeed compared with the cost of renewing worn out and broken parts of machinery due to the lack of it. Once let the oil tank run dry, or, if the oil does not drop properly, the engine soon becomes hot, the piston expands and a broken cylinder is the consequence.

In like manner if the water tank becomes empty and the cylinder is not properly cooled, the latter is again endangered. In cold weather should you forget to empty the tank after a trip and the water should freeze, a bursted cylinder, again, is almost certain to result.

It may be readily seen that a needless expense of a hundred or more dollars incurred while cutting one's wisdom teeth, is not only possible, but more than probable.

Finally, it is not wise to buy a second hand car until the machinery has been laid bare and every separate bolt and part seen and examined. It is the renewal of worn parts that adds to the purchase price and one should know just what he is getting before agreeing to pay any fixed sum.

THE ELECTRICAL PART.

The electrical part is much simpler than one would expect to find, yet the battery and connections must be just right or the engine will balk. The gas engine operates through the explosion of gas in the heads of the cylinders and each explosion forces the pistons outward. The explosions are caused by an electric spark from an induction coil and occur within the cylinders where the spark plug "points" are concealed.

The accompanying diagram shows the general method of wiring. There are, of course, different

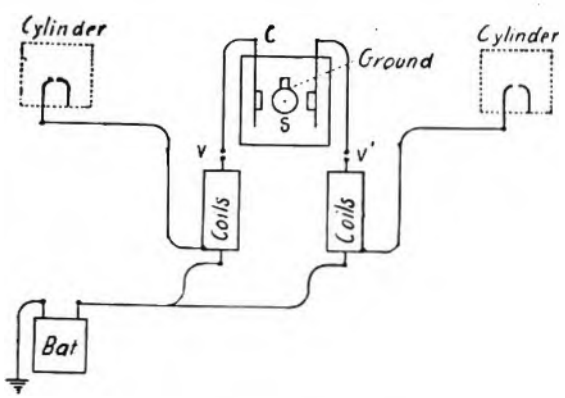

FIG. 1.—WIRING DIAGRAM.

ways of making the connections, but the principle involved is the same for all machines using battery and induction coils.

It will be seen that there are no "return" wires to the battery. By connecting the negative pole of the battery to the metallic body of the frame of the car and grounding the terminals of the various circuits leading from the positive pole in like manner, as illustrated, the frame acts in the capacity of a return wire and we have practically a metallic circuit.

C is what is called a commutator, but is in reality merely two metal springs which form the terminals of the two primary windings of the spark coils. *S* is a revolving shaft with a cam or projection on it which makes contact with each of the primary terminal springs during one revolution, and being "ground-

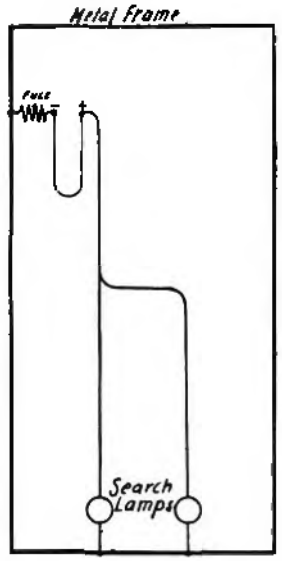

FIG. 2.—LAMP CONNECTIONS.

ed" completes the circuit. During contact with spring *V* or *V'*, as the case may be, it breaks the circuit and causes the secondary coil to discharge, thus creating a spark in the cylinder spark plug. As contact with the companion terminal is just half a revolution distant the gas in each cylinder is exploded and discharged separately while the other cylinder is refilling. Fig. 2 shows how the connections may be made for utilizing 6-volt electric lamps instead of an acetylene gas generator. The one battery will suffice for both lamp and spark and makes a dazzling headlight.

998,719. Telephone System. To C. A. Simpson, Chicago, Ill.

999,019. Cooling Device for Telephone Transmitters. To C. E. Egner, Stockholm, and J. G. Holmström, Saltsjö-Storängen, Sweden.

The Postal Telegraph-Cable Company.

EXECUTIVE OFFICES.

Mr. E. J. Nally, vice-president and general manager, has returned from his vacation.

Mr. C. P. Bruch, third vice-president, is absent on a vacation.

Mr. H. A. Tuttle, president and general manager of the North American Telegraph Company, Minneapolis, Minn., was a recent executive office visitor.

Mr. W. D. Francis, superintendent of supplies, who has been seriously ill for some weeks is slightly improved.

Mr. F. B. Travis, manager of the Washington office of this company for the past four and a half years, has been advanced to the managership of the Boston office. Prior to his appointment to the Washington position, Mr. Travis was for fifteen years chief operator at Boston and is therefore well qualified to assume the important duties of his new position. He was tendered a farewell dinner and reception by the heads of the various departments of the office at Washington on the eve of his departure, and was presented with a purse of gold.

Mr. G. M. Foote, assistant manager of the Washington office of this company has been appointed manager to succeed Mr. F. B. Travis. Mr. Foote has been connected with the Washington office for the past four years in various capacities and is familiar with every detail of the business.

Mr. O. M. Grier has been appointed manager of the Macon, Ga., office to succeed Mr. O. T. Moore, who has been transferred to the managership at Raleigh, N. C.

Mr. Henry Morlan has been appointed manager of this company's office at Salt Lake City, Utah, vice Mr. C. B. Turpin resigned.

The Postal Telegraph-Cable Company has adopted the use of five dashes to signal a cipher in automatic work. This signal is the cipher of the Continental code.

Mr. J. B. Havice, who was recently appointed assistant chief operator of the Postal Telegraph-Cable Company, New York, was born at Leetonia, Ohio, December 22, 1871. In 1885 he entered the telegraph service as check boy for the Western Union Telegraph Company at Columbus, Ohio, afterwards becoming an operator. In 1889 he was appointed manager of the Western Union office at Clintonville, Pa., and between 1890 and 1897 he worked as operator at various places for both the Western Union and Postal companies. Since the latter year he has been with the Postal Company almost continuously, receiving his appointment as assistant chief operator in June of this year.

Limits of Western and Southern Districts of Postal Company.

The district limits and superintendents of the Western and Southern Divisions of the Postal Telegraph-Cable Company are given in *The Postal Telegraph* as follows:

WESTERN DIVISION.

First district, H. G. McGill, superintendent, Chicago, comprises the lines and offices in what is known as Greater Chicago.

Second district, E. W. Collins, superintendent, Cleveland, Ohio, comprises the lines and offices in Ohio (except Toledo) and West Virginia, as at present.

Third district, J. F. Looney, superintendent, Chicago, Ill., comprises the lines and offices in Illinois and Missouri, except Chicago, Kansas City and St. Joseph.

Fourth district, A. L. Lafferty, superintendent, Chicago, comprises the lines and offices in Southern Michigan and Toledo, Ohio.

Fifth district, A. B. Richards, superintendent, Kansas City, Mo., comprises the lines and offices in the states of Kansas, Nebraska and South Dakota, and also offices in Kansas City and St. Joseph, Mo., and Council Bluffs, and Sioux City, Iowa.

Sixth district, W. P. S. Hawk, superintendent, Chicago, comprises the lines and offices in the state of Indiana.

Seventh district, W. C. Black, superintendent, Denver, comprises the lines and offices in the states of Colorado, Wyoming, New Mexico and Eastern Arizona; also Ogden and Salt Lake City, Utah, and El Paso, Texas.

Eighth district, C. A. Comstock, superintendent, Chicago, comprises the lines and offices in Wisconsin, Northern Michigan, Iowa (except Council Bluffs and Sioux City), and Minnesota.

SOUTHERN DIVISION.

First district, C. H. Ashburn, superintendent, Atlanta, Ga., comprises the lines and offices in the states of Virginia, North Carolina and South Carolina.

Second district, G. W. Ribble, superintendent, Atlanta, Ga., comprises the lines and offices in the states of Georgia and Florida, except Pensacola.

Third district, C. B. Arrington, superintendent, Atlanta, Ga., comprises the lines and offices in the states of Alabama, Louisiana and Mississippi, and Pensacola, Fla.

Fourth district, W. C. Daviet, superintendent, Atlanta, Ga., comprises the lines and offices in the states of Kentucky and Tennessee.

Melting Carbon.—It is reported in *Annalen der Physik* that La Rosa conducted experiments which indicate that carbon can be melted.

Digitized by Google

Western Union Telegraph Company.

EXECUTIVE OFFICES.

Messrs. Belvidere Brooks, general manager; Mr. G. M. Yorke, engineer and W. N. Fashbaugh, traffic engineer, New York, have returned from their Western trip.

Mr. Belvidere Brooks, general manager, gave a reception to the messenger boys in Minneapolis during his recent visit in that city. He shook hands with the boys and greeted each with a few words of advice and cheer.

Mr. E. M. Mulford, division commercial superintendent and Mr. A. C. Kaufman, commercial agent, New York, have returned from a trip throughout the Maritime Provinces.

Mr. W. J. Dealy, general superintendent of the Commercial News Department, New York, is again at his desk much improved by his rest in the Adirondacks.

Mr. C. F. Ames, district commercial superintendent, Boston, Mass., and Mr. J. W. Reed, district commercial superintendent, Philadelphia, Pa., were recent executive office visitors.

Mr. T. E. Fleming, of the general manager's office, New York, is on a trip to Chicago and other Western points on company business.

Mr. C. B. Turpin recently manager of the Postal Telegraph-Cable Company's office at Salt Lake City, Utah, has been appointed manager of the Fresno, Cal., office of this company.

Mr. G. A. Lockwood has been appointed manager of the Portsmouth, Ohio, office of the Western Union Telegraph Company, vice Mr. Roy Zimmerman who has been transferred to the Cincinnati office.

This company has improved and extended its facilities between Boston and Canso, N. S., in order to better handle the increasing cable business between Boston and European points.

The office of this company at Columbus, Ohio, is being entirely remodeled both as to the telegraph and telephone equipments and facilities for handling a large increase of business will be provided.

Personal.

Mr. Franklin J. Scherrer of New York has returned from a business trip to Chicago and Omaha.

Mr. Ronald Mayer, identified with the telegraph department of the Texas Company at Houston, Tex., was a recent New York visitor.

Mr. W. H. Butler, assistant superintendent American District Telegraph Company of New Jersey, at Philadelphia, was a recent New York visitor.

Mr. F. G. Jones, identified with the Western Union Telegraph Company at Jacksonville, Fla., for many years, was a New York visitor last week and took occasion to call on many of his former friends.

Mr. Thomas A. Edison, accompanied by his son Charles, sailed for Europe August 2 on the steamer *Mauretania*. He will meet Mrs. Edison and Miss Madeline Edison in London, and the party will spend two months touring England and the Continent.

Mr. C. F. Annett, of Jerome, Idaho, a well-known old time telegrapher, is represented in a cartoon, among a lot of other public spirited men of Jerome, in a recent number of "Illustrated Idaho." Mr. Annett installed the first telephone in Idaho and the cartoon shows him holding a telephone in his lap. Mr. N. Annett, his son, is also pictured.

The Cable.

Extension of Pacific Cable.—The British Pacific Cable Board has been authorized to extend the Pacific cable from Australia to New Zealand.

Atlantic Cable Rates.—In the course of a discussion in the Canadian House of Commons recently, the Postmaster-General, Mr. Lemieux, stated that he had been informed by Mr. H. Samuel, Postmaster-General of England, that the English and German cable companies had agreed to a reduction of the rates to 6d. a word for "semi-urgent" messages not in code, but that the French companies were holding out against the reduction. It was hoped that the difficulty would soon be overcome.

The Telephone.

Telephone Chief Operators Meet.—The chief operators of the Southwestern Telegraph and Telephone Company held a conference in Little Rock, Ark., August 4 and 5, for the benefit of the service. Mr. L. M. Loring, division superintendent of traffic, presided.

Large Telephone Mortgage. — The Federal Telephone and Telegraph Company has filed at Buffalo, N. Y., a mortgage for $25,000,000 on its property in ten counties in Western New York. Various independent telephone companies were recently consolidated with the Federal company.

Telephone Consolidation in Colorado and Utah. —The Mountain States Telephone & Telegraph Company has been incorporated as a result of the merger of the Colorado Telephone Company and the Tri-State Telephone & Telegraph Company with the Rocky Mountain Bell Telephone Company.

Automatic Telephone Exchanges. — An automatic telephone exchange of the Strowger type is to be installed at Epsom, England, by the Post

Digitized by Google

Office. For the purpose of comparison it has been decided to install one of the Lorimer system at Caterham, the capacity being 500 lines in each case.

Long Distance Telephony in Europe.—Telephonic communication was successfully established between Paris, France, and Aberdeen, Scotland, a distance of about 1,000 miles. Communication was made by way of London, Dover and Calais. It is stated that it was possible to hear quite distinctly and that there was no "buzzing."

Protest Against Advance of Telephone Rates.—The board of supervisors of the county of Orleans and the board of trustees of the village of Albion, N. Y., has filed a protest with the Public Service Commission, Second District, against the increase of rates by the New York Telephone Company in Albion and vicinity.

Telephone and Telegraph Stockholders.—The American Telephone and Telegraph Company has 50,000 stockholders, the Western Union Telegraph Company has 14,000, and The Mackay Companies' shareholders also run up well into the thousands. The United States Steel Corporation has 120,000, the Pennsylvania Railroad Company 65,000, and the Standard Oil Company 7,500. Notwithstanding the general outcry against trusts the number of stockholders in these large concerns is increasing rapidly. The stocks in any one of them, it may be stated, are widely distributed and are held chiefly by persons of moderate means.

Radio-Telegraphy.

High Power Wireless Station.—It is stated that the new wireless telegraph station at the Charlestown, Mass., Navy Yard will have twice the power of the present station.

United Wireless Declared Bankrupt.—The United Wireless Telegraph Company was declared bankrupt in the United States District Court at Portland, Me., and Mr. Seldon Bacon of New York was appointed general receiver for the corporation.

Wireless Telephony in Army Manoeuvres.—During the recent manœuvres of the National Guard at San Francisco the wireless telephone was successfully used in communicating with warships off shore.

Indicted for Tapping Wireless.—E. J. Earl, of Los Angeles, Cal., has been indicted for "tapping" a wireless and publishing a private message. This is a felony under the California laws and is punishable with a five-year imprisonment and a fine of $5,000.

Wireless Amateurs Organize.—The Rochester Wireless Association, which is composed of amateur wireless operators, has been organized in Rochester, N. Y. E. T. Eastman is president; M. D. Mosher, vice-president; G. A. Hickson, treasurer; J. M. Albert, engineer, and F. A. Wright, secretary.

Municipal Electricians.

Fire Alarm Wires Underground.—The fire alarm telegraph wires in Cincinnati, Ohio, are to be placed underground.

Association of Municipal Electricians to Meet in Atlantic City.

Owing to the death of S. W. Manning, superintendent of fire alarm telegraph, St. Paul, Minn., as announced in our issue for August 1, the executive committee of the International Association of Municipal Electricians, of which Mr. Manning was chairman, has decided to change the meeting place of the next convention from St. Paul to Atlantic City, N. J. The dates of the convention will not be changed, therefore the meeting will be held at Atlantic City, September 12, 13, 14 and 15. Young's Hotel has been selected as the headquarters, and ample space for exhibits of apparatus, etc., will be arranged for.

Mr. J. W. Kelly, Jr., chief of the electric bureau of Camden, N. J., has been detailed to make hotel and other arrangements at Atlantic City for the convention. Further information may be obtained from secretary C. R. George, Houston, Tex., or Mr. J. W. Kelly, Jr., Camden, N. J.

The change from St. Paul to Atlantic City will no doubt receive the hearty approval of the members, as that famous resort is more central and accessible and for these two reasons a larger number of members will be in attendance. Nothing will be left undone by those having the arrangements in charge to make this meeting a successful one in all respects.

As already announced, Mr. Manning was killed by an electric shock received while investigating some trouble on fire alarm wires at the fair grounds in St. Paul, on July 19.

Obituary.

Death of W. D. Sargent.

W. D. Sargent, aged 67 years, an old time and military telegrapher, and well known in telephone circles, died in Somerset, Pa., August 10. Mr. Sargent studied telegraphy at Harrisburg, Pa., and was in the United States Military Telegraph service in 1863. In 1866 he was manager of the Harrisburg office, and in 1871 was assistant electrician for the Western Union Telegraph Company at Chicago. He became interested in the telephone in Philadelphia in 1877 and was general manager of the telephone company in that city until 1882 when he accepted the position of vice-president and general manager of the New York and New Jersey Telephone Company, with headquarters in Brooklyn, N. Y. At the time of

Digitized by Google

his death he was a director of the New York Telephone Company and a member of the Old Time Telegraphers' and Historical Association and the Society of the United States Military Telegraph Corps as well as of almost every other electrical organization.

He was one of the best known telephone officials in the United States and a man of lovable nature, which won for him a wide circle of friends.

J. C. Duncan, a member of the Military Telegraph Corps, died at Knoxville, Tenn., August 1.

L. Ford Perdue, a member of the United States Military Telegraph Corps, died at Terre Haute, Ind.

John E. Jayne, a member of the United States Military Telegraph Corps, died July 27 at Dewitt, Mich.

J. E. Neale, superintendent of telegraph of the Great Indian Peninsula Railway, died at Calcutta, India, recently. He was the inventor of the block signaling apparatus used on that and other lines in India.

Dr. P. J. Burns, a prominent physician in the Borough of the Bronx, New York City, and a former telegrapher, died in that borough, August 4. Dr. Burns was one of the most skilled operators for many years and graduated from the key to the practice of medicine in which he also became very proficient.

Frank B. Williams, chief operator of The Associated Press in Louisville, Ky., died in that city August 8. He was one of the first operators to be employed when that Association established its leased wire system in 1886, and was employed in the New Orleans office before going to Louisville. Mr. Williams established a record of receiving on the typewriter for a month without a break.

Joint Reunion of Old Timers and Military Telegraphers.

The interest in the approaching reunion at Atlantic City, N. J., on September 5, 6 and 7, of the Old Time Telegraphers' and Historical Association and the United States Military Telegraph Corps is growing rapidly and from present appearances there will be a large and especially representative attendance.

The military telegraphers are planning to make the fiftieth anniversary of the founding of their Corps an event of historical importance and no member of that Corps who can possibly be present should fail to answer to his name at the roll call which in the order of nature is certain to be the last for many of the present survivors.

The Old Timers proper will of course be on hand in large numbers. Unlike the Military Corps their ranks are always being refilled.

One feature of special and of general interest as well is that Mr. Edward L. Morse, of Stockbridge, Mass., a son of Professor Samuel F. B. Morse, the inventor of the telegraph, will attend the reunion and it is stated that Prof. Alexander Graham Bell, inventor of the telephone, may be induced to be present.

Honorable W. S. Jordan, Mayor of Jacksonville, Fla., is an old operator. He is a member of the Old Time Telegraphers' and Historical Association and has forwarded a pressing invitation on behalf of his city and many old time telegraphers to select Jacksonville as the Convention city for 1912.

Those desiring additional information should communicate with secretary F. J. Scherrer of the Old Time Telegraphers' and Historical Association, 30 Church Street, or Mr. D. H. Bates, secretary of the Society of the United States Military Telegraph Corps, 658 Broadway, New York.

The Resistance of Insulating Materials.

An investigation of the resistance of different forms of insulating material has recently been carried out by W. Deitrich, who has reported the results in the *Physikalische Zeitschrift*. The materials to be tested were in the form of cylindrical rods, which were connected to a charged electroscope and the rate of leakage observed. The insulation of hard rubber, caoutchouc, sealing wax, paraffin, etc., were found to be affected by the action of light, the material apparently acquiring a surface conductivity.

Moisture had a similar effect upon shellac, paraffin, beeswax, sealing wax and resin. Different kinds of wood were also investigated. When dry their insulation stood in the following order: pine, walnut, fir, beech, oak. When in a moist condition the order of insulation was oak, walnut, pine, fir, beech. In investigating different kinds of glass it was found that a gradual rise in temperature resulted in a gradual fall of resistance.

Origin of "Deadhead."—It is stated that "deadheads" originated in Pompeii where ivory markers were used as entrance checks to theatres. These checks were of different shapes to differentiate the various parts of the amphitheatre to which they gave admittance. Those for the top row were, for instance, represented by a bird, and those entitling the holder to free admission were small death's heads. Thus originated the expression "deadhead."

Exports of Electrical Apparatus.—During the fiscal year ended June 30 the value of electrical appliances exported from the United States was $10,700,000, as compared with $8,700,000 the year previous. The value of electrical machinery exported was $8,000,000, against $6,000,000 the previous year.

Practical Aspects of Printing Telegraphy.

In our issue for June 1 we published an abstract of a paper entitled "Practical Aspects of Printing Telegraphy," read before the Institution of Electrical Engineers, London, by Mr. Donald Murray, inventor of the printing telegraph system bearing his name. Since the publication of the paper Mr. Murray has received from the Direction General of Russian Posts and Telegraphs an official letter giving some interesting information in regard to the employment of the Murray automatic system on the telegraph line between St. Petersburg and Omsk. The letter, translated into English, is as follows:

"In reply to your letter of February 28, 1911, concerning the adaptation of the Murray apparatus to the telegraph line Omsk—St. Petersburg, the Direction General has the honor to inform you that this line has a length of 3,557 kilometers (2,224 miles), and has three repeating stations, namely, at Riazan, Samara, and Tcheliabinsk, arranged at the following distances: St. Petersburg —Riazan, 865 kilometers (541 miles); Riazan—Samara, 872 kilometers (545 miles); Samara—Tcheliabinsk, 1,004 kilometers (628 miles); Tcheliabinsk—Omsk, 816 kilometers (510 miles).

"The line is of iron wire and measures six millimeters (0.236 inch) in diameter. It is worked duplex in an entirely satisfactory manner, and it is not necessary to revert to simplex except in the case of very bad atmospheric conditions.

"The regular operation of the Murray automatic apparatus on the St. Petersburg — Omsk line was inaugurated on April 19, 1908. The speed of transmission in each direction working duplex, is from fifty to sixty words a minute. The speed of transmission by the Wheatstone system on the same line did not attain more than thirty words a minute (six feet of tape), rarely thirty-five words (seven feet of tape), and under the very best conditions, and then only during very short periods of time, forty words a minute (eight feet of tape).

"The foregoing practical results show that the effective speed of transmission on this line is far below the theoretical speed obtained by calculation. This difference appears to be due not only to atmospheric conditions, but also to the influence of the self-induction of the line, and, above all to the influence of the induction of neighboring wires running parallel with this line over long distances."

The speeds are given in words per minute and are reckoned on the basis of five letters and a space equal to a letter per word. That is to say, they correspond to six typewriter letters or their equivalent space. The speeds of fifty-six to sixty words a minute are therefore equivalent to 336 to 360 letters per minute. The Wheatstone speeds are on the same basis.

How Mr. Lincoln Received the News of His First Nomination.

In an address delivered before the Illinois State Historical Society, Mr. Clinton L. Conkling gave a very interesting account of how Mr. Abraham Lincoln received the news of his nomination by the Republican National Convention in Chicago, May 16, 1860, and described the part played by the telegraph in that memorable event. Mr. Lincoln was at Springfield at the time and received reports of the progress of events at the convention by telegrams, letters and persons returning from Chicago.

The following account of the service rendered by the telegraph on that occasion is taken from Mr. Conkling's address, which was published in the transactions of the Illinois State Historical Society, and the accompanying illustrations of the telegrams sent to Mr. Lincoln announcing his nomination were kindly loaned to us by the Society:

"The only wires into Springfield in 1860 were owned and operated by the Illinois and Mississippi Telegraph Company and were called the "Caton Lines" after Judge John D. Caton, of Ottawa, Ill., president of the company, and one of its organizers. Its principal office was at St. Louis. John James Speed Wilson, afterwards known as "Colonel Wilson," was superintendent of the Eastern Division, with headquarters at Springfield. Mr. E. D. L. Sweet was superintendent of the Western Division, with his office in Chicago. These divisions were afterwards called the Southern and Northern divisions, respectively. Mr. C. F. McIntire, with an operator named J. B. Pierce, was in charge of the local office in Springfield, which was then on the north side of the public square. Upon the absorption of the Illinois & Mississippi lines by the Western Union Telegraph Company in 1866, Mr. Sweet was appointed superintendent of the latter company, and upon his resignation in 1868, Colonel Wilson succeeded him and removed to Chicago. He continued in that position until 1879, when he resigned to go into other business. He died a few years afterwards. Mr. E. D. L. Sweet died in Chicago last March. During the convention he had charge of all the telegraphic arrangements. There was only one wire into the "Wigwam," and this was connected in the main office with the eastern wire of the Western Union—it being the general opinion that the nomination would go to an eastern man, Seward being the one most often mentioned in that respect. Mr. Wilson was in Chicago during the convention and divided his time between the main telegraph office, at the southeast corner of Lake and Clark streets, and the convention in the "Wigwam," a building erected for the occasion at the corner of Market and Lake streets. Most of the personal messages from delegates to Illinois points were sent from the convention hall to the main office of the Caton Company by messenger boys.

"In my possession are five original telegrams received by Mr. Lincoln on the day he was nominated. All are on the Illinois and Mississippi Telegraph Company form.

CATON LINES.

Illinois and Mississippi Telegraph Company.

IN CONNECTION WITH ALL OTHER LINES IN THE UNITED STATES AND CANADAS.

TERMS AND CONDITIONS ON WHICH MESSAGES ARE RECEIVED BY THIS COMPANY FOR TRANSMISSION:

The public are notified, that, in order to guard against mistakes in the transmission of messages, every message of importance ought to be repeated, by being sent back from the station at which it is to be received to the station from which it is originally sent. Half the usual price for transmission will be charged for repeating the message. This Company will not be responsible for mistakes or delays in the transmission or delivery of unrepeated messages, from whatever cause they may arise, nor will it be responsible for damages arising from mistakes or delays in the transmission or delivery of a repeated message, beyond an amount exceeding two hundred times the amount paid for sending the message, nor will it be responsible for delays arising from interruptions in the working of its Telegraphs, nor for any mistake or omission of any other Company over whose lines a message is to be sent to reach the place of destination. All messages will hereafter be received by this Company for transmission, subject to the above conditions.

FIG. 4.—MESSAGE TO MR. LINCOLN ANNOUNCING DETAILS OF VOTE.

Digitized by Google

"The first one sent was from the telegraph superintendent, Wilson, and shows signs of haste and bears no date. It reads:

"'To Lincoln:

"'You are nominated.

"'J. J. S. Wilson.'

"Mr. Pierce, the operator who received this message at Springfield, writes from Young America, Ill., under date of June 4, 1860, to Mr. Lincoln, saying that this was the first message for him announcing his nomination.

"A moment after this message was sent a messenger boy brought to the main office in Chicago a message addressed simply 'Abe,' and which read, 'We did it. Glory to God.' 'Knapp.' The receiving clerk brought the message to Mr. Sweet, calling his attention to the address, and also to the expression 'Glory to God.' Mr. Sweet directed that the words 'Lincoln, Springfield,' be added and that the message be sent at once.

"The next two telegrams are from J. J. Richards, who was well known in earlier days in Springfield. He was connected with the Great Western Railroad Company and was its agent for some time at Naples, which was then the end of the road. He subsequently went to Chicago.

"These telegrams are as follows:

"'May 18, 1860.

"'By Telegram from Chicago, 18 1860.

"'To Abraham Lincoln;

"'You'r nominated & elected.

"'J. J. Richards.

"'——————18——————

"'By Telegraph from Chicago 18——18——

"'To Hon. A. Lincoln:

"'You were nominated on 3rd ballot.

"'J. J. Richards.'

"Mr. J. J. S. Wilson followed his first message, probably within a very few moments, by another, which reads:

"'——————18——————

"'By Telegraph from Chicago 18 1860.

"'To Hon. A. Lincoln:

"'Vote just announced. Whole No., 466; necessary to choice, 234; Lincoln, 354 votes, not stated. On motion of Mr. Evarts of New York the nomination was made unanimous amid intense enthusiasm.

"'J. J. S. Wilson.'"

How the Kaiser's Telegram Went Astray.—The following story is told in England in connection with the investiture of the Prince of Wales at Carnarvon. In the course of the day a telegram reached the post office addressed "Prince of Wales, Carnarvon." It was handed to a boy messenger in the ordinary course, and without any special instructions, and he marched off with it to the Prince of Wales Hotel. The landlord opened the missive, and was aghast when he read the contents. It was a message of congratulations and good wishes to Prince Edward from the German Emperor. The telegram was immediately delivered in the proper quarter.

QUESTIONS TO BE ANSWERED.

[The success which has attended our plan of publishing in each issue a list of questions covering the subjects considered in Jones' Diagrams, has encouraged us to maintain the work through other books. Students of telegraphy throughout the country are finding these questions of great assistance in their studies of the general principles underlying the operation of the apparatus with which they come in daily contact. Many consider this the best plan which has yet been devised for a systematic study of the technical side of the telegraph. Having completely covered Mr. Jones' book we are now covering "The Quadruplex," by Maver and Davis, and will bring out, in a like manner, all the facts that every telegrapher should know about duplex and quadruplex telegraphy as found in this book.]

CHAPTER VII. *(Continued.)*

Referring to Fig. 29, what is the bar of the pole-changer electrically connected with?

After leaving the pole-changer the circuit divides. What is the course of each part?

Which battery supplies the current that passes in and out of the home artificial line?

In Fig. 30 what is the resistance Q' placed between the condenser and rheostat wire for?

In balancing a quadruplex what is the effect of grounding the wire at the distant station?

When a line is thus grounded why is the previous balance not disturbed, when the resistance of the battery is removed by turning the switch?

After restoring the full battery power to the line how is the balance obtained?

If the polar relay responds to the motions of the pole changer what does it indicate?

How is this action neutralized?

How is the polar duplex balanced?

How is the Stearns duplex balanced?

CHAPTER VIII.

In introducing the dynamo-electric machine as a means of supplying energy for the operation of duplexes and quadruplexes, why was it necessary to alter the arrangement of the instruments?

How many grades of potential are supplied by these machines?

What are the values of the potentials?

Why are resistance coils placed between the generators and the wires?

What are the resistances of the various coils used for this purpose?

What potential is used for long quadruplex circuits?

What wires are supplied by current of the first potential?

What by the second and third potentials?

For short wires what potential is used?

How is the resistance of these wires increased?

Is the current supplied by generators limited?

What effect has the movements of the transmitter upon the current?

What effect has the action of the polechanger upon the current?

Long-Distance Telegraphy.

It has been stated in electrical engineering circles that telegraphy has practically reached the limitations of development and that it is at a standstill, but those who are familiar with the facts know that nothing is further from the truth. The mistake made by those who take this view of the matter rests on the assumption that because the telegraph is the oldest of the electrical arts it must necessarily be dormant as far as progress and improvement are concerned, if not decadent.

The later electrical developments, such as electric lighting, the electric railway, etc., have occupied the stage for several years simply because they are comparatively new and in the development stage, but they, too, are advancing toward the point where startling changes may no longer be looked for. From that point improvement will be attained through refinement of existing apparatus and processes as is being done in the telegraph and the telephone today. The telegraph particularly is undergoing a refining process at the present time that was not even dreamt of a few years ago. The spirit of progress and improvement has come to the front and truly wonderful things are being accomplished in a quiet way.

One of the greatest achievements in telegraphy in recent years is the increase in the range of operation of the wires. A few years ago the longest regular circuit worked out of New York was to New Orleans, and, when conditions were favorable Galveston was directly connected. Improvements in apparatus and line construction have rendered it feasible to span the continent with an unbroken line of communication. Chicago used to be the practical limit of operation direct from New York, and all business for the West was sent to that office for distribution to destination. Now, Chicago and other former large repeating points are relieved of much of the great volume of traffic by handling direct business between large centers. At the present time New York is in regular direct communication with St. Paul and Minneapolis, Denver, Salt Lake City, San Francisco, Los Angeles, Seattle, and all other important points in the West; Dallas, Houston, Galveston, etc., in the Southwest and Havana, Cuba, and circuits are established direct to other points as business warrants such special facilities. Of course it is understood that these long circuits are not composed of one direct wire between the terminal points. They are divided into sections by repeaters and there is no physical reason why lines many times as long cannot be operated directly by means of this important apparatus, the repeater. Indeed, one cable company works direct from New York to Buenos Ayres, Argentina, a distance of 8,000 miles by the aid of repeaters, and another from New York to Emden, Germany, 4,300 miles.

The most important advantage gained by these improved methods of handling business is the saving of time and the reduction of the liability to error. These two factors are probably the most important a telegraph company has to consider with respect to its functions as a public service corporation, and the more it succeeds in eliminating them the better it will serve its purpose and live up to the quality of service a telegraph company should give to its patrons.

The Value of Study.

The value to students of technical telegraphy of our "Answers to Questions" column is evidenced by the number of letters we receive bearing on the subject. The great value of the matter lies in the necessity of investigation and inquiry and getting underneath the surface of things to find out why. The mere statement that a sounder works when an electric current passes through the coils does not mean much, but when the question "Why?" is applied to the case a wide field of investigation is opened up and the possibility of much extended and real knowledge on the subject is laid within the grasp of the student. All he has to do is to diligently use his thinking faculties and ask and answer questions and knowledge will come to him.

The quadruplex and the duplex and accessory apparatus constitute the subject of investigation in this column at the present time and on account of the growing importance of these systems of telegraphy deep interest is being shown in them by students. Apart from the mental satisfaction that comes with the increase of knowledge, the specific information gained by study of these questions is of the highest value to the student as it broadens his mental horizon and fits him to fill higher positions. The call to step up higher may come at any time and the more an operator

Digitized by Google

knows about the whys and wherefores of his business the more is he likely to be called upon to exercise his knowledge for the benefit of the company employing him.

Every operator should find out as far as he can the cause of things and not be contented with effects alone. An effect does not tell us anything except that there is a cause back of it. An operator can work a wire, but can he connect the wire; select and assemble the proper instruments, generators, switches, batteries, etc., and put them together so as to produce a workable circuit? That is the kind of knowledge the telegraph companies need in their men.

A Good Example.

The Western Union messenger boys of St. Paul evinced as much pleasure and pride at having been greeted by General Manager Belvidere Brooks in that city recently as does the average farmer in shaking hands with the President of the United States. The effect in both cases is to promote loyalty, one to the employer and the other to the state, and no doubt it would be beneficial on both sides if the practice of bringing superiors and subordinates together were indulged in more frequently. The employes would feel the stimulus for good engendered by occasional social communion with their superiors and the companies would be benefited thereby. Let the officials show more interest in the welfare of the employes and peace and harmony in the service will be promoted and realized.

Mr. Brooks himself was once a messenger and it is gratifying to note that he appreciates the fact that the messenger of to-day is just as human as in the time when he was one of them and is as sensitive and appreciative of encouragement and a good word now and then from the superior officers.

Notifying Mr. Lincoln of His Nomination for President.

One of the greatest figures in American history is Abraham Lincoln and people never tire of reading about his character and achievements. Mr. Lincoln had a familiar knowledge of the telegraph by reason of the circumstances existing at the time of his incumbency as president of the United States and anything that connects him with the service is of perennial interest to telegraph people.

A very interesting lecture was delivered by Mr. C. L. Conkling before the Illinois State Historical Society in which that gentleman told how Mr. Lincoln, in 1860, received the news of his nomination for the presidency. The telegraph of course was the means utilized, and Mr. Conkling exhibited the original telegrams conveying the announcement to Mr. Lincoln. Four of these we have the pleasure of reproducing elsewhere in this issue, together with the story of their origin and delivery.

The article contains facts of much telegraphic as well as historical interest and will no doubt be read with much pleasure and profit.

Corrosion of Lead Sheaths of Telegraph Cables by Stray Electric Currents.

Prof. Pionchon has been investigating the corrosion of lead sheaths of telegraph cables by stray currents in Dijon, France, and *La Revue Electrique* of Paris contains a report of the results.

By taking continuous records of the potential difference between two points in the water pipes, Prof. Pionchon showed that an electric current was flowing through the same; at night time when the street railways were not running the registration became a straight line, and during the day electrical conditions were dependent upon the operation of the cars. Analogous results were obtained by measuring the difference in potential between the flowing water and a nearby railway track, the voltage reaching a value as high as twelve volts. Similar results were obtained between telegraph cables and the rails, the observed voltage being considerably in excess of any that might be formed by lead, earth and rails acting as a primary battery. The direction of the current flow was from the lead cable-covering to the rails, and consequently the lead became corroded. As a further test of the fact that current was flowing from the lead sheath, cotton which had been soaked in a solution of potassium iodide was placed between the lead sheath and the wall of the conduit. This cotton became discolored within a few hours by the passage of current in the day time, but at night no effect was observed. In other parts of the city it was found that the direction of current flow was away from the rail and as high as twenty-five volts was observed at certain points.

Telepost Employes Strike.

The offices of the Telepost Telegraph Company in St. Louis, Sedalia and Kansas City, Mo., and Chicago, were closed July 31. It is stated that dissatisfaction over irregularity in paying salaries was the cause of the trouble and that a number of the employes claim that three weeks' salaries have not been paid. Mr. H. Lee Sellers, of New York, president of the company, stated that the difficulty is only temporary.

The company had a line between Chicago and St. Louis, part of which was leased from an independent telephone company. This line was in continual trouble and on account of this the situation became so acute that the Telepost Company strung a wire of its own in place of the one leased. Subsequent work on the line kept the wire out of commission a great part of the time, and under such circumstances business suffered. He has been assured by every one of the company's managers that if the wires could be relied upon the business would largely increase, and, he states, the company "would be on a very satisfactory profit earning basis."

Aspects of "Public Ownership."*

BY SYDNEY BROOKS.

The area within which public ownership may safely be invoked by all municipalities in all lands is, in short, extremely small; and the far larger and more debatable area within which public ownership fails at one spot and succeeds at another is so broken up by the infinite variety of local conditions as almost to defy classification or description as a whole. * * * We want to know the best method of regulating public utilities that are owned and operated by private corporations. We want to ascertain, if possible, some fairly broad and not too rigid principle that would help us to separate the services that ought to be taken over by the municipality or the State from those that might legitimately be left in private hands. We want, again, to strike an approximate balance between (1) public ownership combined with the lease of the undertaking to an unofficial corporation, (2) public ownership combined with public operation, and (3) private ownership and private operation under public control. Assuming that the advantage is found to lie with the system of public ownership combined with public operation, we want, next, to discover how this system works—what are its financial effects in relieving taxation or in increasing local indebtedness, whether the services it supplies are of a better quality and lower in price than those which might be obtained from a properly regulated private company, what consequences result from the creation of a body of privileged workmen drawing higher pay from the public authority than they would receive from an ordinary employer, how far the expansion of State and municipal activities and the increase of State and municipal employment of labor affect the tone and character of politics and the interest of the people in their civic and national affairs, how far they react upon private enterprise and influence the flow of capital and the state of the labor market, and what, finally, are the conditions, political, legal, administrative and "atmospheric," that give to public ownership its best chance of success.

Preservation of Pole Timbers.

Bulletin No. 84, recently issued by the United States Forest Service, is devoted to the preservative treatment of poles. Present knowledge of the results of the creoscte treatment of wooden poles is based largely on treatments made by the pressure method, using from eight to twelve pounds, or more, of creosote to a cubic foot of timber. The expense incident to such treatment has been the chief hindrance to its more general adoption for poles. Investigations of the Forest Service have therefore been concerned with treatments which could be applied locally without the erection of elaborate and extensive plants. Much attention has also been given to the seasoning of poles, since proper seasoning not only prepares poles to receive the preservative, but under certain conditions may be in itself a means of increasing their durability.

Seasoning of poles reduces their weight usually from sixteen to thirty per cent., and even more for some species. In general, poles cut during the spring and summer lose weight most rapidly; those cut during the autumn and winter lose less rapidly, but more regularly.

Preservative applied to the surface of a pole by a brush may add from one to two years to the life of timber, but permanent protection should not be expected from the application of so small a quantity of the material. If the butt be more deeply impregnated, the life of the pole will probably be limited by the life of the top rather than by that of the butt. A life of twenty years for butt-treated chestnut and western cedar, and twenty-two years for northern white cedar poles is believed to be a conservative estimate. In the drier western climate butt-treated pine poles can probably be depended on to give twenty years' service.

Impregnation of many pole timbers may be accomplished in open tanks, without the use of artificial pressure, by immersion in hot and cold preservatives, the cold following the hot. The open-tank process has the advantage that it is possible to apply the preservative to the butts only, with a great saving in the creosote.

Conversion Factors.

The following tables will be found useful for converting English units of measure into metric units, and vice versa:

MEASURES OF LENGTH.			
Millimeters	×	0.04	= inches
Inches	×	25.	= millimeters
Centimeters	×	0.4	= inches
Inches	×	2.5	= centimeters
Meters	×	3.28	= feet
Feet	×	0.31	= meters
Kilometers	×	0.621	= miles
Miles	×	1.61	= kilometers
Kilometers	×	3281	= feet
Feet	×	0.0003	= kilometers
MEASURES OF CAPACITY.			
Cubic centimeters	×	0.06	= cubic inches
Cubic inches	×	16.4	= cubic centimeters
Cubic meters	×	35.3	= cubic feet
Cubic feet	×	0.03	= cubic meters
Liters	×	1.06	= quarts
Quarts	×	0.95	= liters
MEASURES OF AREA.			
Square centimeters	×	0.16	= square inches
Square inches	×	6.45	= square centimeters
Square meters	×	10.77	= square feet
Square feet	×	0.09	= square meters
MEASURES OF WEIGHT.			
Grammes	×	15.4	= grains
Grains	×	0.06	= grammes
Kilogrammes	×	2.20	= pounds (avoir.)
Pounds (avoir.)	×	0.45	= kilogrammes

High Speed Automatic Perforators.

BY DONALD MURRAY, LONDON, ENGLAND.

In reference to the very interesting article on high speed automatic perforators by Mr. William Maver, jr., in your issue of July 16, the following points that have occurred to me may perhaps be worth publishing.

The use of a high speed perforator to perforate tape purely for retransmission (in order to regenerate signals on a long line) is of doubtful utility. Any paper perforating mechanism is necessarily complicated and needs frequent skilled attention. A duplex line would require two sets of these retransmission perforators at the repeating station, and two sets of paper rolls. Assuming that the circuit exchanged 1,000 messages a day there would be required ten coils of eight-inch Wheatstone tape, amounting to over one ton of paper tape per annum, costing not less than $250 for paper alone, to say nothing of the cost of the apparatus and the skilled mechanical and other attention required. There are also the errors and break-downs inevitable with such apparatus.

I speak from experience because the Murray automatic system was one of the first of the high-speed automatic telegraphs that exactly reproduced the perforated transmitting tape at the receiving station. The Russian administration was struck by the possibilities of automatic retransmission for regenerating the signals on long lines, and tried the Murray automatic system in this way. The experiment, however, was soon abandoned as not being worth while. It was found preferable to work the Murray automatic system through ordinary Wheatstone duplex repeaters.

On the other hand for a telegraphic receiving and distributing centre, the received perforated tape will undoubtedly prove very useful in future years. It is obviously a valuable facility if messages can be received, say in Chicago from New York, in the form of perforated tape and sorted out and automatically retransmitted over various circuits.

For purely regenerative automatic retransmission of signals a much better plan than the employment of perforated receiving tape is in use in connection with the Baudot system, and the principle can be applied also to other multiplex systems such as the Rowland, and the Murray multiplex. It is a purely mechanical system of regenerating the signals at a repeating station without the use of tape. In the Baudot it is a distributor that receives the worn out and distorted signals and sends them on as perfect new signals equal to the originals. There are many of these retransmitting stations on the continent of Europe; for instance, on the Baudot quadruple line between Paris and Berlin there is one of these mechanical regenerating repeaters at Coblenz.

I have devised a similar arrangement for the Murray automatic system. The apparatus in this case can be made for about $200 or for about $400 in the case of a duplex repeating station, that is to say for less than the cost of two years supply of paper tape for the perforated tape plan. The principle is the same as in the Baudot, and the signals are retransmitted as good as new. There is no tape. It is purely a mechanical contrivance. It will repeat Morse signals as readily as it does the Baudot signals employed in the Murray automatic system. The speed in the case of Morse signals is limited to about 100 words a minute, but this is ample for long lines. The one drawback to the arrangement is that the speed must be uniform. This condition applies also to the Baudot and all the other mechanical regenerators yet invented. Theoretically it should be possible to make a Morse signal regenerator which would be free from this necessity for uniform speed.

Diseases of Storage Batteries and Their Cure.

Storage batteries, like any other mechanical contrivance, are subject to troubles; but they have troubles of their own besides, that are not to be found in any other energy-producing machine. These troubles are of a chemical nature, and are so insidious and detrimental to the operation and life of the storage battery that they have received very careful investigation. Fortunately the nature of these diseases are now so well understood that the proper remedies can be applied.

The following description of the diseases of storage batteries and their remedies, taken from Dr. Watson's book on storage batteries, covers the subject very concisely.

Diseases of the apparently mechanical order are the buckling, warping, or other distortions of plates, flaking off or falling out of the active material, and hardening or crumbling of plates due to exposure to air. It is rather remarkable how fully these causes, together with kindred ones such as loss of capacity, reversal of negative plates, and internal discharge, can be attributed to "over-sulphation," or what is more commonly called merely "sulphating."

As seen from the equations that denote the probable chemical actions during the charge, the lead is first changed into the sulphate and then into the spongy metallic or highly oxidized condition; that is, the sulphate is a natural stage between the two extreme conditions found on negative and positive plates. In the normal action of the cell, sulphate is formed no faster than it can be reduced to either of these two forms by the action of the current. Also, during the discharge, both plates tend to return to the condition of the sulphate. If an excess of sulphate is formed, a cell may be expected to manifest it in some or all of the manners just mentioned.

The sulphate in itself is almost a non-conducting body, and when on a plate it effectually removes the covered portion from further action. Acid that is too strong or too weak is conducive to this formation, likewise long periods between use and successive charging. Of course, the sul-

Digitized by Google

phate forms unevenly on the outer surfaces of plates, therefore leaving some parts more active than others, and though the grids may be of symmetrical shape and of equal mechanical strength in different parts, serious warping may result. Films of sulphate may form between the active material and the walls of the grids, thereby leaving the pellets quite insulated from the main circuit. The charging would then be confined to a smaller than the expected quantity of material, and the capacity of the cell be proportionately reduced. With its proper hold on the grids relaxed, the pellets will flake or fall out, resulting in a permanent loss of actual volume of plate. With only a small resulting capacity, such cells are more quickly discharged than those in proper condition, and if the normal discharge is maintained, current from the other cells will continue to flow through the exhausted ones, and reverse their polarity.

The sulphate is readily detected by its white color, and is usually to be looked for on the negative plates only. The outer and visible surfaces of these plates may exhibit some sulphate, even when the other parts are healthy, for these surfaces are so remote from positives as to be largely inert.

Three practical methods may be followed for removal of the undesirable sulphate, depending upon the size of cells and means at hand, as well as upon the severity of the case; the user would select the one most available of the three.

One method is to charge the cells at a slow rate for a long time. Where no immediate urgency for the use of the cells exists, this is perhaps the most practicable plan. If the main cells are in daily use, the defective ones may receive an equivalent treatment by connecting *them* in on the charge, but switching or cutting them out of circuit during the discharge. Large cells, in which the positives of one are permanently joined to the negative of the next, could obviously not utilize this method. A whole double set of plates would require removal and the substitution of a spare set while the faulty ones were being treated in some special vessel. A more common method is to saw off the faulty plates, one by one, replacing them as fast as removed by new or freshened ones.

A second method, highly practical and effective, is temporarily to reverse the negative plates. This process should be carried out, not with the regular positives, or they would be seriously injured, but with "dummies," mere slabs of sheet lead used as positives. By this reversed action of the current, the sulphate will be thoroughly converted to peroxide, and then when returned to regular formation there will be the normal quantity of spongy lead free from excess of sulphate. Except for such actual loss of material as may have resulted from flaking, this process restores a plate to almost its original vigor.

A third method may be followed when it is imperative to repair a cell in the shortest possible time, or when the plates have long been dry and exposed to the air. Carbonate of soda is added to the electrolyte, and the normal charging rate maintained until the plates resume their normal color. When restored in this manner, the contaminated solution must be withdrawn, the plates thoroughly washed and set up with fresh solution.

Aside from the internal discharge between plates due to the bridging of pellets of active material, dislodged by sulphating or other causes, discharge may result from the presence of impurities contained in the original materials or absorbed from the air. Particularly pernicious is the presence of even small traces of nitric acid that may have been used in the forming processes. If cells are located in a stable or near refrigerating apparatus, from which ammonia fumes may be absorbed, nitric acid will at once be produced, and the cells possibly ruined. If such locations are unavoidable, the use of a layer of paraffin oil on the electrolyte is an effective safeguard.

From some unexplained reason, direct sunlight seems to encourage the warping of plates. Therefore, while it is highly desirable to locate batteries in places where plenty of light may be had to allow for thorough inspection, an excess should be avoided; direct sunlight, too, would produce unnecessary evaporation of the electrolyte. Heat is conducive to chemical action. At ordinary temperatures a substance may be quite unacted upon in a given solution, but let the liquid be heated, say to boiling, and dissolution or other action may quickly follow. So with the storage cell. At ordinary temperatures the unwanted actions may be entirely absent, but in a room heated to over 100° F. these chemical changes may be permitted. It is certain that temperatures uncomfortable to person are also unfavorable to battery maintenance.

New Book.

Wireless "Hook-Ups" is the title of an 88-page booklet gotten up by H. Gernsback and issued by the Modern Electrics Publication, New York. The matter consists of a complete collection of wireless telegraph and telephone diagrams for wireless experimenters, with a chapter on the study of diagrams. The booklet contains 165 illustrations of different "hook-ups," besides others, making a total of 171. The various illustrations are clearly drawn so that the amateur will have no trouble in tracing the connections and circuits. The pamphlet does not pretend to be the final word on the subject, but merely an aid to amateurs to get the best results from their equipment. All of the standard and other wireless systems are represented.

The price of this book is 25 cents, and copies can be obtained of TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

ANSWERS TO QUESTIONS.

[In this department questions on matters of a practical character, and of general interest, will be answered. Questions intended for this department must be signed by the writer's full name—not for publication, but for identity. No attention will be paid to anonymous communications.]

(60) Q. What is the value of one lux in the measurement of illumination? W. T.

A. The magnitude of one lux is approximately 1/12 foot-candle. The foot-candle is the illumination of one standard candle at a distance of one foot.

(61) Q. What is the present market price of radium? P. M.

A. Radium is such a scarce and precious substance that it can hardly be said that there is a market for it. A gram of radium, costing $72,000, was presented by Sir Ernest Cassel to the British Radium Institute. As there are 454 grams in one pound, it can be easily calculated what a pound of radium is worth, at that rate. But there is not a pound of radium in the world, and any one having a few grains of it lying around loose better take what he can get for it and not wait for a market quotation.

(62) Q. Of what material are the standard insulators in this country made, and are the same kinds of insulators used in England? I have been told that different insulators are used in the latter country. C. A. C.

A. Glass is the standard material for insulators in this country, although porcelain insulators are becoming more and more used. In England glass insulators are almost unknown, ninety-five per cent. of the insulators now in use being of porcelain, the rest being of stone ware. An excellent article on porcelain and glass insulators was published in our issue for January 16.

(63) Q. (1) What insulating material is used for long submarine cables, and (2) is an Atlantic cable of the same size throughout is entire length? G. P.

A. Gutta percha is almost universally used, because its electrical, physical and mechanical qualities improve from submergence at great depths. Vulcanized rubber is also frequently used as insulation, especially for cables laid in certain tropical waters where the teredo attacks gutta percha. (2) A deep sea cable is not the same size its entire length. It is made up of three sizes: the shore end, the intermediate, and the deep-sea.

Measuring the Length of Wires by Vibrations.

Mr. C. A. Smith of Birmingham, England, describes in *The Electrical Review* of London the results of some experiments which he recently conducted with a view to determine distance by means of vibrating wires.

The method is both accurate and simple, he states, and should have an important application to the measurement of distances betwen poles or wire supports, when the bases are inaccessible. Such cases frequently occur where the wires cross over house property, and particularly abroad, where they pass over mountain gorges, and over water or swamps.

Referring to the propagation of wave motion in a horizontally suspended wire, supported at both ends, if the wire be struck, or "plucked," near one end, a transverse wave results, which travels at a uniform velocity to the distant end. On reaching the far end, it is reflected, and continues to traverse the wire to and fro several times, always maintaining the same velocity, but gradually falling in amplitude.

Since the velocity is uniform, it follows from the equation expressing the velocity of propagation of waves along a stretched wire or cord, that, if we know the exact time in seconds taken for the pulse to reach the distant end, also the tension applied to the wire, and its weight per unit length, it becomes a simple matter to calculate the length or distance traversed.

The equation, which may be found in any text book on physics, is

$$v = \sqrt{\frac{T}{m}}$$

where T is the tension applied and m is the mass of unit length of the wire in absolute units.

In the experiments Mr. Smith used a dynamometer to determine the tension upon the wire to be measured. At each tension the wire is struck at a convenient distance from the draw-tongs and the exact time observed for the fifth return to reach the experimenter's hand held on the wire. This time interval is divided by ten to give the time taken for the wave to travel in one direction. Several readings should be taken at each tension and plotted as ordinates on cross section paper, the abscissas representing time. From a curve thus drawn the distances can be readily calculated.

New Directors and Officers of Westinghouse Company.

At the adjourned meeting of the stockholders of the Westinghouse Electric & Manufacturing Company, held July 29, directors were chosen as follows: James S. Kuhn, Edward M. Herr, Pittsburg; Edward F. Atkins, Boston; Charles T. Brooker, Ansonia, Conn., and Harrison Nesbit of Pittsburg. Robert Mather was chosen chairman of the corporation, and the following officers were elected: President, Edward M. Herr; vice-presidents, Loyall A. Osborne, Charles A. Terry and Harry P. Davids; acting vice-presidents, George W. Hebard and H. D. Shutte; controller and secretary, James C. Bennett; treasurer and assistant secretary, T. W. Siemon; assistant secretary, Warren H. Jones; assistant treasurer, H. F. Baetz; acting assistant treasurer, S. H. Anderson; auditor, F. E. Craig, and assistant auditor, W. B. Covil, Jr.

The new president, Mr. Herr, has since 1905 been vice-president of the company in active charge of its manufacturing commercial operations.

Observations on Telephone Transmission.*

BY J. L. MCQUARRIE, OF NEW YORK.

(*Concluded from page 512.*)

To one called upon to furnish telephone facilities the important problem is to determine in detail what construction should be employed in order to obtain the required result at a minimum cost. The difference in price between the very best and an inferior instrument is so small that there should be no excuse from a financial point of view for the purchase of inferior transmitting or receiving apparatus. Compared with the cost of the lines, the differences in the price between the very best telephone apparatus and the poorest is infinitesimal. The largest economies, therefore, which it is possible for one planning a telephone system to achieve are accomplished by savings in line construction and by the use of such methods of operation as will secure the maximum use of the facilities provided.

In dealing with this phase of the problem it is first necessary to establish a standard of transmission which it is desired to furnish. Preferably this standard of transmission should be expressed in miles of standard cable, although if it is so desired it can be expressed in terms of an open wire copper circuit of a given loop resistance or weight per conductor per mile. If different classes of lines are to be considered, it may be advisable to have two standards, one for a certain class of service, perhaps the bulk of that which is being considered; the other for a certain special class of service which represents but a small percentage of the total amount. For instance, it might be desirable to fix for certain classes of service a 20-mile standard, while for other classes of service a 30-mile standard might be considered satisfactory.

Having established the standard of transmission, I may point out certain general principles for guidance in determining the most suitable construction. If the circuits are to be wholly of open wire, the problem is comparatively simple. If copper wire is to be used, mechanical strength limits the engineer to the use of wire not below 160 or 175 pounds in weight, although climatic conditions, such as sleet or high winds, must be taken into consideration. Very approximately where copper is used the length of line over which it is possible to give the desired standard of transmission is inversely proportional to the resistance of the circuit per loop mile. To illustrate, if transmission between two substations of a standard type is satisfactory over a 400-mile line of 210-pound copper wire having a loop resistance per mile of approximately 8.5 ohms, then an equal grade of transmission can be given over a circuit 200 miles in length by using copper wire weighing approximately 105 pounds per mile and having a resistance of approximately 17.0 ohms per loop mile. However, as the latter size of wire under ordinary conditions does not possess satisfactory mechanical strength, it is necessary either to use larger copper wire or to use bi-metallic wire, selecting in this case a size and grade of wire which will provide mechanical strength with a resistance not in excess of that of the 105-pound copper conductor, or 17.0 ohms per loop mile.

In the case of cables, the transmission efficiency varies inversely as the square root of the product of the loop resistance and the mutual capacity. Diverging for a moment, since in the past there has been some confusion in regard to the capacity of a cable as affecting transmission, it may here be emphasized that it is the mutual capacity between wires of the pair and not the grounded capacity of a wire or conductor which influences the transmission. However, it can be added that for ordinary paper insulated lead covered cables the ratio of the mutual to the grounded capacity is nearly constant, being approximately two-thirds. Hence, if in one case the mutual capacity is known and in the other only the grounded is available, it is possible to compute the mutual capacity in the latter case and then compare the two cables.

Regarding the capacity of cables, it may be pointed out that, in order to obtain a change in mutual capacity of, say, from .070 to .054 microfarad per mile, it is necessary to very greatly reduce the number of pairs in a cable having a given sized sheath, the reduction in some cases being almost as great as 50 per cent. While it is not possible to formulate a rule applicable to all cases, it has in general been found to be economical to use cable having a reasonably high capacity, that is, a rather compact cable, and then where necessary to increase the transmission efficiency by increasing the size of the conductor one gauge rather than to attempt to secure the transmission gain by a low capacity. This is especially true when the price of copper is low.

The foregoing directions apply to cases where the transmission circuit is wholly a cable line or wholly an open wire line. If of necessity the circuit must be carried for part of the distance in cable and part of the distance in open wire, the problem is much more complicated, since in order to obtain a standard grade of transmission at a minimum cost it is necessary to so proportion the cost of the cable portion of the circuit and the cost of the open wire portion of the circuit as to produce a minimum cost for the whole line.

As the satisfactory quality of telephone transmission depends to a large extent on what is usually termed the maintenance of the telephone lines, it may be of interest to emphasize certain features involved in maintenance. Poor maintenance results in three defective conditions:

1. Decrease in actual telephonic efficiency; that is, the telephone currents themselves, are not transmitted with full efficiency.

2. Noise due to leaks to ground or to adjacent lines, which may be either telegraph, power or lighting circuits.

3. Crosstalk or overhearing from adjacent circuits.

As far as the electrical requirements are concerned maintenance should care for the following

* Abstract of paper read at the Boston convention of the Association of Railway Telegraph Superintendents, June 26-30.

Digitized by Google

points: In order to prevent a reduction in actual transmission efficiency the maintenance should be of such a character that under no conditions of weather will the insulation between the two sides of the circuit fall below a certain permissible minimum. As a matter of fact, however, in the case of actual non-loaded circuits, the permissible minimum for the insulation is rather low if it is uniformly distributed, and not much trouble in practice is encountered in securing a satisfactory value, especially as it is only in cases where insulators become soiled or where the lines come in contact with foliage that the insulation falls, even under the worst weather conditions, to a seriously low value.

Considering the matter of noise and crosstalk, however, the electrical requirements are that the two conductors should themselves be electrically similar and similarly located electrically with reference to all other wires and the earth. By the two wires being electrically similar it is meant that they should be of the same size and of the same material, and that neither wire should contain high resistance joints. By stating that the wires should be similarly located electrically with reference to other wires and to the earth, it is to be presumed that, under the usual conditions, the wires have been balanced by transpositions. If, however, one wire has a large leak to earth at a given point, and the other wire is well insulated at this point, the balance secured by transposition is disturbed and the chances are that the line will become noisy or that there will be crosstalk. For this reason leakage to earth through poor insulation which is not the same for the two wires is very likely to cause noise.

The Pole Industry in Canada.

According to statistics issued by the Forestry Branch of the Department of the Interior of Canada the total number of poles purchased in 1910 was 782,841, an increase of 118 per cent. over 1909. The total value of these poles at point of purchase was $1,043,874, and the average price was $1.33, or less by 6 cents than the price per pole in 1909. Steam railways, telephone and telegraph companies used 95 per cent. of these poles, the remaining 5 per cent. being used by electric railways, power and light companies; 97 per cent. of the total consumption were cedar poles. At present, says *The Railway and Marine World*, none of these poles are treated or preserved by any method, in which respect Canada is far behind the United States, the latter country using in 1909, 3,738,740 poles at an average cost of $1.89, or at 50 cents more per pole than in Canada. It was found that it paid to use preservative methods. During the last three years the treatment of poles has advanced rapidly in the United States, so that in 1909 15 per cent. of the total number were treated by creosote or other methods. This is an increase of 67 per cent. over the number treated in 1908. At present the United States has eighty-seven pole-treating plants, while Canada has none. It is to be hoped that this great inequality will soon be done away with, and that pole users in Canada may take up this cheap and rational method of securing greater service from the poles used and thus lessening the drain on the forest.

Handling Copper Wire.

BY WILLIAM FERRIS.

The handling and stringing of copper wire is a work that requires a great deal of care. In the first instance, we will take the pay-out reels, which are furnished for the work, fitted up with stakes and every time the wire is tightened up the least bit we have four kinks, one at each stake, and every kink lessens the strength of the wire to a certain extent. A drum reel, handled carefully, avoids this damage to the wire.

The next thing is the joints. There is not more than one joint in ten made properly. No workman can do work right without the proper tools. As a rule, if a lineman has climbers and an old pair of pliers and connectors of any style he is supposed to be equipped. Every joint he makes in copper wire with faulty connectors is practically ruined. There are very few connectors made reversible that fit a No. 12 sleeve as they ought, and I have failed to see the connector for No. 8 wire that fits the sleeve perfectly. Without a perfect fit the joint cannot be twisted as is necessary, three and a half turns, without injury to the sleeve. Even the connector of the best make does not seem to fill the bill the way a good connecting wrench does, for the workman can put the wrench on the sleeve and make his turns with ease. The connectors slip and scrape the sleeve and finally split it at the end. This practically ruins it.

If connectors are copper lined it at least helps save the sleeve.

The lineman makes his error by putting the wire through the sleeve, turning it back, and clipping it before making the twist. When the wire is twisted these short ends cut a crease at each end of the sleeve and practically kill the strength of the joint. There is a great deal of this work being done, and as an order is out against it, it is the foreman's duty to see that this order is carried out.

Just a word on tieing in wires. In this work we also have another instance of improper tools being used. I claim the pliers should not be used. Some men will use them all right, but more men will not. Each man should be furnished a tie wrench to fit over the end of the wire, and use the entire tie. A man that never saw one before will make a better tie than the average man makes with the pliers, and injure the wire less.

To handle this work, which I believe is as important construction work as the company has, the foreman should be a very careful, sober and competent man, and his men should be selected from the very best linemen. The company should furnish the proper tools and men, and it will be repaid for the effort by the improvement in the work.

The Military Telegrapher in the Civil War.

PART LIX.

An interesting account of an active telegraph service during the Civil War, showing incidentally the variety of duties the military telegrapher was called upon to perform, is given by Mr. I. D. Maize, of Philadelphia, a well-known old time telegrapher.

Mr. Maize's experience reveals the kind of timber military operators were made of. They were versatile, intelligent and brave, and from all records it is evident that there was nothing that they could not do under stress of circumstances.

"I left Harrisburg, Pa., in August, 1862," writes Mr. Maize, "and was ordered by Colonel J. R. Gilmore to report at Annapolis Junction, where, along with the late Crosby Ryan, we were occupied in running trains by telegraph over the single track between Baltimore and Washington, in transporting a large number of troops into Washington. After being there a week, Colonel Gilmore ordered me to Washington and then sent me down to Kalorama Heights, just below that city, where I was assigned to General Rufus King's brigade. I remained there only a week, when the long roll was sounded one midnight, and we marched to the Chain Bridge, a short distance beyond Georgetown. We encamped there for a few weeks, when another advance was ordered beyond the Chain Bridge into Virginia. There General W. F. (Baldy) Smith was in command and with him were Captain Griffin and Captain Hancock, both in charge of batteries. I was all alone and had very long hours, but, hearing that there was an operator in one of the Vermont regiments, I asked General Smith to detail him, which he did. I found out, however, that he was a Continental operator and of course was no use to me. Another operator, named Fred T. Bickford, was detailed by General Smith to assist me, and a fine one he was. At the time of the general advance of the Army of the Potomac farther into Virginia, the advance was so general that it taxed the authorities at Washington to build lines fast enough, and as the material to build these lines had been sent out I told General Smith that if he would give me a hundred soldiers I would build the line, which he did. The soldiers went to work with a will. We dug the holes, placed the wires on the poles as they lay on the ground and then hoisted them up, and between the hours of 8 a. m. and 5 p. m. we had built five miles of loop in a heavy rainfall all day.

"On arriving at the new camp I found that no place had been provided for the operators. General Smith saw an outhouse close to his headquarters, which were in a magnificent Virginia house of about twenty rooms owned by a man named Smoot. We opened the office in this outhouse and found that it was an immense poultry house. After we got in we found that hundreds of chickens, turkeys, guinea hens and geese were to be our companions. We stretched blankets to protect ourselves and in the morning complained to General Thomas T. Eckert, who at once had Mr. Simon Cameron, secretary of war, issue the celebrated order that all operators were to be taken directly into headquarters. After that operators were made more comfortable. D. Brainard Lathrop was also sent here, thus giving us three men at this point, where others had only two.

"When the Army of the Potomac moved down to Yorktown we were left stranded as those men who had been spending the winter in Washington were sent to the front. But Lathrop was ambitious to be at the front, and he walked all the way to Washington, about twelve miles, and succeeded in getting an assignment. He was afterward killed in battle. There were twenty of us left and General Eckert ordered us to Washington, where we were given other assignments. My lot fell to West Virginia. I was halted at Point of Rocks to help Lounsbury and Lawrence with the rush that occurred after the battle of Winchester which was fought the same day.

"After spending five days there, I went to Clarksburg, W. Va., where the late C. O. Rowe was in charge. There was nothing to do there but wait orders. During my stay there I was living at a house that gave us ham and eggs three times a day, nothing else. We would sit in the office during the day and sing the song:

"There is a boarding house
Not far away,
Where they serve ham and eggs
Three times a day.
Oh how those boarders yell
When they hear that dinner bell.
Oh what the boarders say
Three times a day.

"This, set to the tune of America, afforded us much amusement.

"I was then sent to Gauley Bridge at the head of the Great Kanawha River, where I found William Curtis all alone. The office was required to be kept open day and night, and for the two of us it was quite a task. Curtis asked for help and M. H. Kerner was sent out to be night man. He was there only a few days when the operator at Summerville suddenly left and Kerner was sent there, about 18 miles away. He was there only a few days when he was captured and given an excursion to 'Hotel Libby' at Richmond, most of the way being traveled on a razor back horse. I was at Gauley Bridge about six months when I was taken sick and had to return to my home at Huntingdon, Pa. Shortly after I left the place was cleaned out by the Confederates.

"After arriving home I found operators were so scarce that the company went begging for them, and I went to Pittsburgh for a few weeks, but remained there. Captain T. B. A. David very kindly relieved me, and thus ended my army experience which, to me, was more of a picnic than hardship.

"The only fighting I saw was the battle of Drainesville, fought between a brigade of General McCall's division and an equal number of Confederates. General Hancock, who had been promoted to be Brigadier-General, furnished a horse for me and took me out to see the fight."

Mr. Maize is still in active service in Philadelphia, and, although 62 years of age of the time of the telegraph tournament held in that city in Oc-

tober, 1903, he distinguished himself on that occasion by capturing the prize in the Old Timers' contest.

The Retirement of Secretary Pope.

Mr. Ralph W. Pope, for the past twenty-six years secretary of the American Institute of Electrical Engineers, New York, resigned his position on August 1. A committee on resolutions made the following highly complimentary report to President D. C. Jackson, on Mr. Pope's services:

"For more than twenty-six years Mr. Ralph Wainwright Pope has faithfully and loyally served the American Institute of Electrical Engineers as secretary and for the twenty-seventh consecutive year he has again been elected to the office of secretary. The board of directors and the membership at large are of the opinion that by his continuous and honorable service he has attained such a position in the regard and affections of the members of the Institute that he is entitled to some relief from the active executive duties of his arduous position. Therefore, to carry out his own expressed wishes his resignation as secretary has been accepted. In accepting his resignation, the board of directors, in order to give expression to its own feeling of gratitude as well as the feeling of the membership at large, and in order to reward such long and distinguished service, has appointed him to the position of Honorary Secretary, in which capacity the Institute may still have the benefit of his long experience in its affairs.

"In thus complying with the natural and just desire of Mr. Pope the board of directors has thought it well to mark this change by this minute expressing its good will and appreciation, and by pointing out that the term of Mr. Pope's service in the Institute covers many of the most important developments in electrical engineering, and that this period has witnessed the growth of the Institute from the humblest beginning to its present flourishing condition.

"At the time when the art of electrical engineering was practiced principally in connection with the telegraph, Mr. Pope was a pioneer, having in the year 1858 mastered the working of the Hughes printing telegraph. In 1861 he had charge of the Morse telegraph office at Great Barrington, Mass., in which town he was born in 1844. In 1862 and 1863 he was in the service of the American Telegraph Company in its New York, New Haven and Providence offices, and in 1865 he was one of that band of telegraph pioneers who went into the wilds of British Columbia to establish an overland telegraph system with Europe by means of Alaska and Siberia. In 1867 he was with the Bankers and Brokers' Telegraph Company until 1872, when he became an inspector with the Gold & Stock Telegraph Company. While with this company he was promoted to the position of deputy superintendent in 1880, at which time the apparatus used by the Gold & Stock Telegraph Company was considered by many as representing the highest development then reached by the electro-mechanical art. While in the service of the Bankers & Brokers' Telegraph Company in 1867 he was also assistant editor of "The Telegrapher." In 1882 he became manager of the Union Electric Manufacturing Company of New York. In 1884 he was associate editor of "The Electrician and Electrical Engineer." In that same year the American Institute of Electrical Engineers was formed. The next year Mr. Pope was elected its secretary, which position he is about to relinquish. In 1890 he founded the electrical magazine, "Electric Power," and in 1891 he became the editor for electrical terms in the Standard Dictionary. In 1893 under direction of council, his quarters as secretary were established in the rooms of the American Institute of Electrical Engineers in the Electrical Building at the Columbian Exposition, and he was appointed on the committee of judges for the Department of Electricity. While at the Exposition in Chicago he personally met more than two-thirds of all of the members of the Institute at that time. Ever since Mr. Pope has kept up his large personal acquaintance among the members, which is of great importance to a headquarters official.

"During the administration of President Stillwell, Mr. Pope visited a majority of the Sections and many of the Branches of the Institute, and made a study of their development and needs. All of these activities have eminently prepared him for the position of Honorary Secretary, giving special attention to the organization and the interest of the sections and branches."

The committee consisted of Messrs. John J. Carty, chief engineer of the American Telephone & Telegraph Company; George A. Hamilton, treasurer of the American Institute of Electrical Engineers, and an old-time telegrapher, and David B. Rushmore of the General Electric Company, Schenectady, N. Y.

Current Indicator for Morse Relays.

BY E. C. DODGE, CHICAGO, ILL.

The article published in TELEGRAPH AND TELEPHONE AGE of August 1, headed "Current Indicator for Morse Relays," by Mr. J. S. Knapp, of Buffalo, N. Y., reminds me of a simple device which I rigged up in a little station on the Erie Railroad many years ago:

Take a common sewing needle, rub it on the magnets of the sounder (with the local circuit closed, of course), then suspend it by a fine silk thread from the cork in a small bottle, and stand the bottle on the relay anywhere back of the armature. When it is desired to know if anyone is using the circuit look at the bottle. The needle will be dancing a jig inside of the bottle if the line is in use. If the needle is quiet there is no danger of "breaking" in on anyone.

Any book on electrical subjects can be obtained at the office of Telegraph and Telephone Age, 253 Broadway, New York.

An Old Time Telegraph Line.*

BY W. P. S. HAWK, SUPERINTENDENT, CHICAGO, ILL.

It was a beautiful May morning, and the back platform of the Overland eastbound, was taxed to its full capacity. We had lost one hour's time during the night in crossing Wyoming, and it was evident that the engineer, pulling the solid train of sleepers out of Cheyenne, had orders, or made up his mind to make up the lost time, and was soon covering what seemed easily a mile a minute. In my contented whiffing at a good cigar, although naturally noticeable, the flitting by of the telegraph poles on both sides of the track soon ceased to be of further interest, and my eyes caught sight of an old pole line in the distance which later proved to be a one-wire bracket line of very light poles and one apparently of very little importance, but about like a line I at one time fostered, and it looked so natural, I could not help feeling much sympathy for its frailness and wonder at its future, hoping it might some day grow into a more substantial looking and prosperous property. I was returning over the same route traversed when going West some twenty-three years ago, when a resolution was moved, seconded and adopted to "go West and grow up with the country," and so left home, friends and all "to stick it out." A short stop was made in good old Missouri on the way, doing an "OS" job for a short time, but it was soon found that the commercial end of the telegraph was of much more interest, and was taken up in Montana in the late '80s.

The one-wire system comprising nearly 400 miles, mostly prairie line, was kept in fairly good workable condition, but under many difficulties, and delays of three, four and five days were not thought much about at that time. The country was full of cattle. They found considerable relief in fly-time during the hot summer months, using the poles as rubbing posts, and for mile after mile the poles showed a worn wide band about three and one-half feet from the ground. To the inquiries of the tenderfoot this was explained as being a "high water-mark," and he was usually puzzled in looking over the vast prairie to figure it out.

In the early days when the pole line belonged to the Government, the officials were much puzzled for a remedy from cattle rubbing, stampeding, etc., breaking the line down and shutting the different garrisons off from outside connections, and the idea was suggested and adopted of going over the line and driving large spikes into four sides of the poles. This soon proved a remedy as far as the cattle were concerned. The spikes being sharp-cornered resulted in much less weight upon the poles, and likewise less breakdowns from that troublesome source. The Government officials were much elated over this solution of the problem and felt that their means of connection with the outside world would henceforth be more substantial and continuous, but the success of the spike idea was short-lived. The officials were not aware of the fact that they were in reality making a trap into which they must and did eventually fall.

The country was inhabited by thousands of buffalo whose hide was very tough and their hair long and in a short time it was discovered that they came from all quarters to enjoy the ecstasy of having their backs scratched by these spikes. They liked the sensation to the limit, but the pressure of their bodies against the poles knocked the line down, and for months afterwards short sections of the line were gathered up over an area of many miles around. Some of the wire became so tightly entangled in the horns of the sturdy pioneers of the plains that it was found a hundred miles north across the Canadian border. Almost a complete new line had to be built, and much heavier poles were shipped from Michigan, and then transported by boat up the Missouri River to the little town of Fort Benton, at the head of navigation. From there they were distributed by freight outfits, in those days made up by means of three or four wagons fastened together and hauled by from twelve to fifteen teams, all controlled by one driver with a jerk line. This line proved sufficiently strong, and aided by the thinning out of the buffalo, it served a good purpose for many years, and was eventually sold by the Government in 1887. It was the start of the first real commercial telegraph competition in the northwest country, the company being known as the "Rocky Mountain Telegraph Company."

A connecting line arrangement with the Canadian Pacific and Postal Telegraph companies was formed that year, the lines having been extended north from Fort Assinnaboine, Mont., across the border by way of what in those days was known as Battle Creek and Fort Walsh to Medicine Hat, on the main line of the Canadian Pacific. The relay office remained at this latter point for a number of years, later being moved to Dunsmore, then to Swift Current and Winnipeg. The old line and connections were the nucleus of what is now as good and substantial property as modern construction can produce. The property was purchased by the writer in 1893, who operated the company as proprietor and general manager until July 1, 1898, when the lines were purchased by the Postal Telegraph-Cable Company.

The company began business in the summer of 1887 when its connections were completed through to the Canadian Pacific, and there are few or no lines nowadays managed as was the old Rocky Mountain Company in the earlier days of its existence.

As manager of the Fort Benton, Mont., office my duties also involved repairs to the line for a distance of 24 miles south to Springs Stage station and 35 miles north to the Coal Banks, a landing for the Missouri River boats. The pole line carried only one wire and when that was out of commission everything was at a standstill. It was

* The Postal Telegraph.

Digitized by Google

not an uncommon thing for the writer to hang out the notice: "Office closed account of line down and the operator out on repairs."

In this work not a great deal of real pole climbing with spurs was often necessary. The sandy soil of the prairie was of such a nature that the old or broken-off stub of the pole could with care be removed and a hole with fairly good walls left. The wire was usually repaired and fastened to the insulator from the ground, the pole shouldered and dropped into the hole and tamped, and the job was finished. This was rendered possible by the one-wire and light poles which had become very light from years of bleaching in the dry altitude.

As the train proceeded the old Wyoming line reminded me of the old days of the Rocky Mountain, and as I watched it as we flew by, and the conditions continued to grow worse, I was soon convinced from the long stretches of fallen poles and broken wire, that it was an abandoned telephone line, which had very likely outlived its usefulness. The poles did not extend beyond the next little town. The line, being a single wire grounded system, had evidently met a natural death, and had been buried there, and as I looked up again at the signboard on the depot it read "Pottersfield."

Improvised Repeaters.*

BY C. A. COOK, PORTLAND, ORE.

The writer was called upon to supply, at short notice, single-line repeaters in addition to the regular equipment. There being eight or ten Atkinson half sets at hand, these were adapted for use as full-sets in the manner shown in the accompanying diagram. There was, however, added to each a three-point switch, the lever of this switch being connected to the ground terminal of the transmitter coils. The left disk of the switch was connected to the ground wire which was removed from the ground terminal of the transmitter coils so that when the lever was thrown to that side the set was practically unchanged. The right disk of the switch was connected to the regular local feed wire of say 26 volts.

In the illustration only one half set is shown, the other half being an exact counterpart and connected with it by means of the connecting cord shown at the right of the diagram.

To use any two half-sets thus equipped as one full-set, insert their duplex wedges in a shorted jack as shown, and the two half-sets then will operate together as one full repeater: their main-line single wedges of course being inserted in the lines to be repeatered.

The convenience of this arrangement is manifest inasmuch as the half-set main-line wedges are usually distributed along the different sections of the switchboard, and their duplex wedges grouped in front of the loop-board, where any two may be coupled together in the spare-jack. This jack, it will be seen, serves to connect the face of one duplex wedge to the back of the other, and vice versa, thus placing the transmitter of one set under control of the relay of the other set.

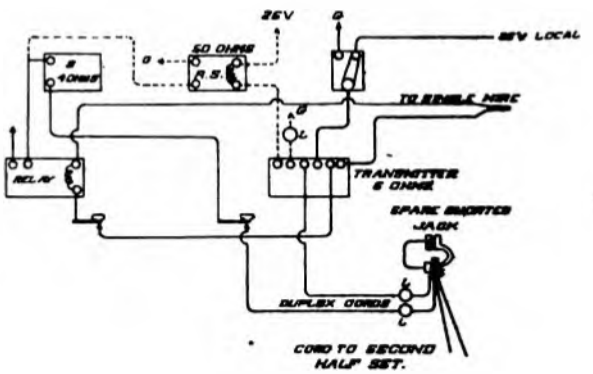

DIAGRAM OF ONE-HALF OF IMPROVED REPEATER.

This makes an excellent, quick-breaking full-repeater, and one that may be relied upon on bad-working wires; and it has given such good results that a number of sets have been similarly equipped. Another point in favor of this arrangement is that its use as a full repeater does not in the least detract from its utility as a half-set.

*Reprinted from last issue on account of omission of cut.

Special Duties of English Messenger Boys.—Awards of special medals for remarkable tasks successfully performed by district messenger boys were made in London recently, when Princess Marie Louise of Schleswig-Holstein presented prizes to about 200 of the boys. Messenger Alfred Beale, it was stated, was sent to Paris to deliver a large box, then to Rome with a dress suit for a high official of the Italian Court, and then to Belgium, where he had to meet the Grand Duke of Mecklenburg at Liege station with a luncheon basket. Another messenger, named Robbins, brought an elephant and its Indian keeper from Brixton to the Palladium and back, and rode on the animal's back on the return journey. A third boy was sent for in hot haste to a house in Bond street, where he found a terrified lady standing on a table. She refused to descend until the lad had captured the mouse which had frightened her. Messenger Cliff was engaged by some irate residents of Kensington to suck a lemon in front of a German band performing in the street. He was threatened by one of the performers, but he kept on sucking. What happened to the band is not stated.

Age Limit Bill Vetoed by Governor Dix.—Governor Dix of New York has vetoed a bill passed by the Legislature providing that a man employed by a railroad company in the operation of telegraph, telephone or signal system shall be 21 years old and have had one year's experience. The Governor believes the present law fixing the age of 18 as sufficient.

Selective Telephone Dispatching in the Philippine Islands.

BY L. G. JACKSON, ILOILO, P. I.

In April, 1908, I accepted a position as trainmaster for the Philippine Railway Company and, before leaving the States for the Philippines, I was requested to look over the most successful methods and devices for dispatching trains by telephone. Having lived in Alaska for the preceding three years, my knowledge of selectors was extremely limited and, as far as I was able to learn, but two railroads in the United States were experimenting to any extent with selective telephone equipment. Fortunately, I was advised to call on Mr. G. H. Groce, superintendent of telegraph, and Mr. E. Parsons, assistant superintendent of telegraph of the Illinois Central Railroad at Chicago, who were trying the Sandwich selectors in actual service, and a trip to Kankakee, where the dispatchers were located, convinced me of their adapatibility for such work. My time being limited, I hurried to the Pacific Coast, where I secured a few men for various positions in our work in the Philippines, and sailed from San Francisco on May 26, arriving at Iloilo, Panay Island, on June 28.

The conditions I found on arrival in the Philippines were discouraging. In order to successfully carry on the work undertaken it was necessary to speak Spanish, Visayan (a Filipino dialect) and English and it appeared to me at once that the telephone would serve our purpose far better than the telegraph. An outfit was therefore ordered by cable and I am quite certain it was the first shipment made outside of the States. Upon its installation many predicted absolute failure and on this point the writer was not anxious to argue either way until he had gained more knowledge of its efficiency during the severe weather we are subject to in the Philippines during certain periods of the year.

For six months the service was excellent but after this period the severe lightning began to burn out one part and then another, until I almost gave up hope of preventing their complete destruction. Lightning on this particular island is as severe as any place in the world during the months of March, April and May. After trying many kinds of fuses I failed to overcome the burning out of coils and other parts. I then secured standard telegraph switchboards with a large brass ground plate with 1/32 of an inch air-gap between line and ground plate. This with quarter-ampere fuses eliminated all trouble from lightning and now only an occasional replacing of a fuse is necessary which can be done by anyone employed in an office.

During the severe stormy season lightning often destroys five and six poles in succession, notwithstanding the fact that they are of the best grade of hard wood and every fifth pole provided with a lightning arrester wire. The lightning often burns the wire as if cut by pliers midway between poles. After overcoming the troubles mentioned the selectors rendered excellent service. They are easily maintained and require only occasional minor repairs. I would not advise any one religiously inclined to come to the Philippines to handle telephone work. One is compelled to employ an American lineman, who doubtless came to the Philippines as a soldier, without any vocation. It is necessary to show him every detail from A to Z besides being called upon to straighten out the smallest complication.

The Philippine Islands have now rapidly approached a condition of prosperity. This is especially true of the Island of Panay where 72.3 miles of first class railroad have been constructed, serving a densely populated area and with enough first class sugar land to produce 500,000 tons of that staple each year as well as many other products. On this line of railway concrete and steel have been used in all structural work, on account of the heavy rainfall. All station and trainmen are natives with the exception of three or four Americans, who will soon be replaced by natives.

Salaries of natives are small in comparison with salaries paid in the United States, but this is on account of their limited capacity for high class work, and taking into consideration the cost of their food and clothing, they are as well paid as men in similar positions in the States.

The Telegraph in India.—According to the annual statement issued from the India office the telegraph system under the direct control of the Indian Government consists of 72,420 miles of line, 283,374 miles of wire and 327 miles of cable. A table is given, showing for a period of five years the progress that has been made in extending public telegraphic communication in the Empire. From this it appears that up to the beginning of the year 1905-1906 the capital expenditure amounted to £5,824,031; the miles of line to 61,684, the miles of wire to 227,436, the miles of cable to 245, and the total number of offices open to the public to 5,986. At the end of the year 1909-1910 the corresponding figures were: Capital expenditure, £7,264,674; miles of line, 72,420; miles of wire, 283,374; miles of cable, 327, and telegraph offices, 7,225. The number of messages in the year 1905-1906 was 10,461,117, with gross receipts of £805,748, and net receipts of £206,606, showing a return of 3.33 per cent. on the capital employed. In the year 1909-1910 the messages had increased to 12,084,697, but the gross receipts had fallen to £795,828, which was not sufficient to cover even the working expenses, and there was a charge on Government revenues of £179,646. The gross receipts fell short of those for any year since 1904-1905. Working expenses, on the other hand, continue to increase.

The Telegraph in Chile.—During the year 1910 2,348,000 telegrams were transmitted over the Chilean government telegraph lines, the receipts showing a gain of 22 per cent. over those of the previous year. There are 367 offices.

Telephone Protector for Outdoor Service.

The type of open space cutout illustrated herewith is in extensive use throughout the country on telephone lines, both in railroad and commercial service, and is manufactured by the Western Electric Company.

This protector is made in two forms—one with a tin cover and the other with a cast-iron cover,

FIG. 1.—PROTECTOR WITH TIN COVER.

which are chained to the framework of the protector mounting, so that they cannot be lost.

The protector itself is mounted on a porcelain base through the bottom of which the leading-in wires are brought in, and consists of heavy carbon blocks as shown in Fig. 2. The spacing between these blocks regulates the voltage at which

FIG. 2.—VIEW OF CARBON BLOCKS.

the protector operates. Under normal conditions, this is adjusted to discharge at 1,000 volts.

The shape of the carbon blocks gives a variable gap between the ground block and the two blocks connected to the line wire. The protectors are arranged so that carbon dust carried across by the discharge will not clog the spark gap, but will automatically drop to the bottom of the protector.

Moisture-Proof Dry Battery for Railway Work.

There are over sixty thousand telephones in use on the various steam and electric railroads of the country, in addition to thousands of miles of signal circuits, therefore, the selection of a proper dry battery is of much importance. A cell for railway work must have, in addition to long life, high efficiency, great recuperative power and high voltage, and should not be affected by moisture. For outdoor work where the dry cells are often not very well protected from snow and rain it sometimes happens that the cardboard cartons of the dry cells absorb so much moisture that when the cells are placed side by side, or on a metallic base, they become short circuited. This causes them to run down and deteriorate rapidly, thus necessitating frequent renewals and an attendant maintenance expense.

The Western Electric Company, realizing this, has recently put on the market for use in railway work a new dry battery. This new cell differs from the company's standard cell in that the cardboard carton has been treated with a special impregnating compound which effectually prevents moisture from reaching the cell proper. This will give sufficient protection so that the life of the batteries used in outdoor work will be as great as that of the batteries used in any other magneto service under ordinary conditions.

Extension of Telephone Train Dispatching on the Great Northern Railway.

The Great Northern Railway, which has nearly 4,000 miles of track furnished with telephone train dispatching equipment, has just placed an order with the Western Electric Company for thirty-two telephone selectors to equip its Cascade division. The circuit will be divided into two sections. The first will extend from Tye to Everett Junction, Wash., with a branch from Monroe to Tolt, Wash., and another from Pacific Avenue to Delta, Wash. The second section will run from Tye to Leavenworth, Wash. The distance covered by the first section will be 93 miles, while that covered by the second will be 36 miles.

Large Storage Battery Plants.—What is said will be the largest emergency storage battery in the world is being installed by the Consolidated Gas, Electric Light and Power Company of Baltimore, Md. Its total weight when ready for use will be approximately 1,079,200 pounds, and it will have an output of 5,517 kilowatts or 7,395 horsepower. This great output will be sufficient to light 220,680 twenty-five watt tungsten lamps for twenty minutes. Very large storage battery plants are also maintained by the electric light companies in other cities for emergency purposes, thus insuring continuity of service. In these plants the chloride accumulator and the "Exide" battery, are used. They are manufactured by the Electric Storage Battery Company of Philadelphia.

The Turner Monument Fund.

Mr. Charles Keck, of New York, the well-known sculptor, is busily engaged on the design of the monument to be erected at Harriman, N. Y., to commemorate the sending of the first telegraph train order in the Fall of 1851. The success of this worthy movement has been made certain through the generosity of Mrs. E. H. Harriman, of Arden, N. Y., who has agreed to defray the expense of the stone and its cutting, and with this assurance the committee having the matter in charge is making its plans to hold the exercises this fall. Mr. C. T. Ford, of Central Valley, N. Y., Mrs. Harriman's superintendent, is co-operating enthusiastically with the committee as that lady's representative, and is lending valuable aid in the work.

A history of the project is outlined in the correspondence between chairman E. P. Griffith of the Monument Fund and Mrs. Harriman which was published in our issue for July 1. From this it will be seen that the success of the movement is assured, but there is yet an opportunity for those to subscribe who have not already done so, and the sooner they send their contributions to the treasurer the easier it will be for all concerned in the work.

G. B. Prescott's book entitled "Theory and Practice of the Electric Telegraph," published in 1860, contains an interesting reference to the Erie Railroad Company's telegraph plant in the year 1855. "They use the Morse apparatus," says Mr. Prescott, who was the leading telegraph authority at that time,—"in the main circuit the Grove battery, and for locals Daniel's improved zinc and copper. * * *

"In concluding this description of the use of the telegraph upon one of the best managed roads in this country, we will say, what strict justice requires, that to Charles Minot, Esq., is due the credit of its inception and completion, in the face of great opposition on the part of other officers of the road, the accomplishment of which has been of inestimable benefit to both the railroad and the public generally."

Mr. John C. Haring, of Piermont, N. Y., sends some further reminiscences (see page 269, April 1 issue) of his experiences on the Erie Railroad in the early days when Charles Minot was general superintendent. He recently called on one of the oldest engineers of the Erie Railroad, Mr. Garry Iseman, who is now 88 years of age but hale and hearty. Mr. Iseman lives in Piermont and while Mr. Haring was talking with him he was spreading hay on his farm. Mr. Iseman, Mr. Haring goes on to say, was the engineer of the mail train waiting at Suffern station for a delayed east-bound train to pass. When the orders came by telegraph from general superintendent Minot and division superintendent J. J. Lawrence to run to Turner the trainmen were greatly surprised, but having confidence in their superiors they obeyed the order and proceeded. Mr. Iseman told his fireman, however, that he would "creep" around the sharp curves, with a keen lookout, and advised that he be ready to jump in case the other train should heave in sight. But none came and they arrived at Turner without a scratch, amid the cheers of those who had been watching for them.

Mr. Iseman in his younger days took an engine from the Grant Locomotive Works at Paterson, N. J., to the Paris Exposition and was in France three months demonstrating the engine on the government railways. On his return to this country he resumed his position on the Erie Railroad. Mr. Iseman has subscribed one dollar toward the monument fund and Mr. Haring will endeavor to have him present when the celebration takes place.

The Monument Fund Committee consists of E. P. Griffith, superintendent telegraph, Erie Railroad, Jersey City, N. J., chairman; Charles Selden, superintendent telegraph, Baltimore & Ohio Railroad, Baltimore, Md.; J. B. Taltavall, TELEGRAPH AND TELEPHONE AGE, New York; E. A. Chenery, superintendent telegraph, Missouri Pacific Railroad, St. Louis, Mo.; W. J. Camp, electrical engineer, Canadian Pacific Railway, Montreal, Canada; Col. W. B. Wilson, president Old Time Telegraphers' and Historical Association, Holmesburg, Philadelphia; F. J. Scherrer, secretary Old Time Telegraphers' and Historical Association, New York. All remittances should be made to Mr. J. B. Taltavall, TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York, who has been elected treasurer of the fund. All contributions are acknowledged in the columns of TELEGRAPH AND TELEPHONE AGE, and the funds deposited with the Washington Trust Company, New York, as soon as received.

Contributions received up to date are as follows: Previously acknowledged, $1,645.25; Garry Iseman, Piermont, N. Y., $1.00; Geo. C. Maynard, Washington, D. C., $2.00; J. L. Henritzy, Denver, Col., $5.00. Total, $1,653.25.

Glasgow Exhibition.—The Scottish Exhibition of History, Art and Industry is being held in Glasgow, Scotland. One of the principal buildings is named Kelvin Hall, in honor of the late Lord Kelvin, the inventor of cable and telegraph apparatus, and famous all over the world as a scientist. In Kelvin Hall is exhibited a collection of apparatus and appliances associated with his name and fame. The eastern wing of the building is devoted to engineering exhibits in all its branches. The exhibition will close in October.

A New Mother-in-Law Joke.—A man has sued one of the telegraph companies for $2,000 damages because of the delay of a telegram which prevented him from attending the funeral of his mother-in-law. What does he want? Some men are hard to please.

KERITE

INSULATED WIRES and CABLES

DEPENDABLE

Kerite Cables installed upward of 35 years ago, and exposed to deteriorating influences, are giving perfect service to-day.

EFFICIENT

Kerite does not rely upon the rubber in its composition for insulating efficiency. Kerite itself is a compound having superior insulating qualities.

SERVICE

A half century of successful service has demonstrated that Kerite possesses the essential qualities of safety, reliability and economy to an exceptional degree.

Kerite Insulated Wire and Cable Co.

The Railroad.

Mr. I. T. Dyer, superintendent of telegraph of the San Pedro, Los Angeles and Salt Lake Railway, Los Angeles, Cal., is seriously ill at the California Hospital in that city.

Mr. M. H. Clapp, division plant superintendent of the Western Union Telegraph Company at Chicago, has been appointed superintendent of telegraph of the Northern Pacific Railway, with headquarters at St. Paul, Minn., vice O. C. Greene retired after an active service of forty-five years.

Mr. E. P. Griffith, of New York, superintendent of telegraph of the Erie Railroad, and Mr. C. H. Bristol, formerly general superintendent of construction of the Western Union Telegraph Company, New York, have returned from an extended trip to Seattle and other Pacific coast points.

The headquarters of Mr. E. C. Keenan, superintendent of telegraph of the Lake Shore and Michigan Southern Railway, are now located in Cleveland, Ohio, having been changed from Toledo where the telegraph headquarters had been located since the formation of that company in 1869.

Mr. Charles Whiting Bradley, acting superintendent of telegraph of the Chesapeake & Ohio Railroad, Richmond, Va., has received the full appointment as superintendent vice J. S. Stevens, resigned on account of ill health. Mr. Bradley was born in Newtown, Conn., in 1836, and began his telegraphic career in 1851 as a messenger on the old Bain line in New Haven, Conn. He was the first telegraph superintendent of the old Atlantic & Great Western Railway, but since 1865 he has been out of the railway telegraph service until January 1 this year, when, on the dissolution of the Western New York Car Demurrage Bureau, he was invited to accept a position with the Chesapeake & Ohio Railway as acting superintendent of telegraph.

English Telegraph Lines Along Railways.—A bill is before the English House of Commons to enable the postmaster-general to carry telegraph wires over railway rights of way without compensation to the railway companies. Three Scotch companies opposed the bill, claiming compensation for the loss of existing rights.

Telephone Train Dispatching.—The Baltimore & Ohio Railroad has ordered of the United States Electric Company, of New York, Gill selector telephone train dispatching outfits complete for forty stations, to be used in the extension of its telephone dispatching circuits from Clarkesburg to Salem, W. Va. A message circuit will parallel the train wire. This installation will complete the train dispatching circuit from Grafton to Salem, and is of interest as a refutation of the report spread about three months ago that the Baltimore & Ohio was to abandon telephone dispatching.

Brady's Civil War Photographs of the Military Telegraph.

The *Review of Reviews* is publishing a fine reproduction of Brady's celebrated photographs of Civil War scenes, one volume of which is devoted solely to the military telegraph, the text in connection with which is from the pen of Major General A. W. Greely, former chief signal officer of the United States Army. General Greely was appointed by President Taft to represent the United States Army at the coronation of George IV. in June last.

Brady's collection shows many telegraphers in the field, singly and in groups, including Colonel William B. Wilson, Colonel R. C. Clowry, William R. Plum, Joseph Schnell, Thomas Morrison and Richard and John E. O'Brien.

General Greely was not connected with the signal corps during the Civil War, and his account was necessarily made up from official reports and other publications. Many of his incidents are taken from the "History of the Military Telegraph," by William R. Plum, and "Lincoln in the Telegraph Office," by David Homer Bates. The account is well written and exceedingly interesting, taken in connection with the large collection of military telegraph scenes.

The following from the Century Company explains itself:

My dear Mr. Bates:—

Please consider that you have our permission to make use of some of your material from "Lincoln in the Telegraph Office" in the book which the *Review of Reviews* is about to publish. It is understood that the enclosed editorial note will be printed giving due credit.

Truly yours,
(Signed) W. W. ELLSWORTH,
Secretary.

(Editorial Note Prefacing General Greely's Account.)

The Editors express their grateful acknowledgment to David Homer Bates, of the United States Military Telegraph Corps, manager of the War Department telegraph office and cipher-operator, 1861-1866, and author of "Lincoln in the Telegraph Office," etc., for valued personal assistance in the preparation of the photographic descriptions, and for many of the incidents described in the following pages, which are recorded in fuller details in his book.

Mr. Robert S. Lanier, who is editing "Brady's Civil War Photographs," is a son of the gifted poet and writer, the late Sidney Lanier.

The employes of the Western Union Telegraph Company, the Northwestern Telephone Exchange Company and the Western Electric Company, of Minneapolis and St. Paul, Minn., held their fifth annual outing recently. The event included a woman's egg race, a fat man's pie-eating contest, woman's tug-of-war, a Marathon moonlight race and an operators' fifty-yard dash.

Large Reproduction of a Cablegram.

The American Medical Association held its convention in Los Angeles, Cal., recently, and was lavishly entertained. One feature of the programme was a visit to the beautiful Busch gardens in Pasadena. Mr. Adolphus Busch, the owner, was absent in Germany at the time, but sent his greetings to the association by cable. A fac-simile of this cablegram was painted on a large sign by the manager of the gardens and this unique greeting attracted much attention. Mr. C. L. Lewis, district superintendent of the Postal Telegraph-Cable Company at Los Angeles, had a photograph made of it a reproduction of which is presented herewith. It shows the company's regular cable blank in perfect proportion and design.

LARGE REPRODUCTION OF CABLEGRAM OF GREETINGS TO AMERICAN MEDICAL ASSOCIATION.

In the group shown in the picture are readily distinguished the faces of superintendent C. L. Lewis and Mrs. Lewis; manager J. H. Dorsey of Los Angeles, and Mr. F. S. Fell, chief clerk to superintendent Lewis.

Boat Excursion by Telegraphers in Pittsburg.

Mr. W. J. Dodge, district traffic superintendent, Pittsburg, Pa., is a strong and consistent believer in energy and the company's business will show satisfactory results from his activity. In order to attain the best results he advocates harmony between all classes of employes, and occasional conferences, in order to bring about a live feeling of co-operation and friendly rivalry. In referring to a recent traffic conference in his district, he says: "I have since seen instances convincing me that harmony among all chiefs, which I believe to be one of the first essentials, reigned supreme, and that each was doing his best to make all employes their friends, extending the spirit down the line and endeavoring to inspire keener interest in the service on the part of all."

He, with the co-operation of employes of the various departments hit upon an excellent plan to bring the operators, clerks, and other employes of the company and their families together, as one family, to get better acquainted with one another socially, and thus bring about a more harmonious feeling along business lines. This plan took the form of a river excursion on the evening of July 17. Mr. Dodge, general traffic chief Larimore, and his entire force of supervisors and as many operators as could be spared from duty, together with their respective families, took part in the excursion and a delightful time was enjoyed by every one. In every respect the outing was an unqualified success, and steps have already been taken to have another one soon. The entertainment on board consisted of dancing and euchre playing, and much enthusiasm was displayed by the participants in both forms of pastime. Mrs. T. J. Ferguson, wife of operator Ferguson, won the prize for ladies in the euchre contest, and Mr. J. C. Ford, a broker operator in Pittsburg, captured the men's prize. Light refreshments were served during the trip. The committees in charge were as follows: Chairman W. T. Sims.

Dancing—W. T. Schragen, S. B. Harte, W. C. York, S. H. Ratner, W. B. O'Hara.

Reception—E. R. Tilghman, Miss Anna Schiller.

Euchre—F. L. Wheeler, J. L. Meldon, P. F. Lyons, Miss Mary Martin, Miss Sue Callender.

General chairman—H. Ratner.

LETTERS FROM OUR AGENTS.

NEW YORK, WESTERN UNION.

Traffic chief Frank A. Hoag, accompanied by his family, is spending his vacation in Plattsburg, N. Y.

Mr. M. Walton Jones, formerly of Superintendent E. M. Mulford's staff, and at present secretary to the president of the Guayaquil & Quito Railroad, Ecuador, S. A., arrived in this city a few days ago on a two months' leave of absence.

BALTIMORE, WESTERN UNION.

Mr. Samuel T. Shutt, former manager of the Baltimore office, who, on account of ill health, was compelled to resign that position May 1, has returned to Baltimore after a two months' leave of absence entirely restored to health, and is again in service, having been appointed assistant to manager Mr. V. J. Albert, who succeeded Mr. Shutt.

RICHMOND, VA., WESTERN UNION.

J. W. Ware, formerly traffic chief in this office, has gone to the third district as district manager, with headquarters at Jacksonville, Fla. He is succeeded as traffic chief by Mr. C. Keister.

W. N. Reveley, district plant chief, was married on June 14 to Miss Sallie Boyd Cole of Oxford, N. C.

The Electrical Class is being attended with great interest, and much progress is reported. The class is confining itself to a study of the telegraph, it having been decided that this would be more beneficial than a study of electricity in general.

OMAHA, WESTERN UNION.

Mr. Harvey Wolfe, night manager of the American District Telegraph Co., and Miss Mae Curtis, assistant cashier of this company, were married June 27. They spent their honeymoon in Denver and vicinity.

District traffic superintendent J. P. Barnhart has been confined to his home recently with an injury to one of his ankles, received in Wichita, Kan.

Chief operator J. S. Owens lost his mother recently by death at Sedalia, Mo.

Mr. C. M. Trimble, formerly chief operator of this office, has accepted the position as chief clerk to district traffic superintendent J. P. Barnhart.

Mr. Owen A. Wagner, who has been in the hospital for the past three months with blood poisoning, expects to be able to return to work within four or five weeks.

ST. LOUIS, WESTERN UNION.

On the evening of July 26, the officers and members of "The Western Union Electrical Club of St. Louis," accompanied by their families and friends, to the number of about 200, enjoyed a most pleasant outing down the Mississippi River on the steamer Alton. Refreshments were served and dancing, music and social intercourse indulged in to the satisfaction of all. This being the first social function of the Club, it had been looked forward to with unusual interest and anticipation of a good time, and the officers and committees are to be congratulated on the success of their efforts. It is the intention of the Club to give these entertainments at different times in the future that the members may be brought together socially. Among those present were: Mr. W. R. Chapman, district commercial superintendent; Mr. W. J. Armstrong, district traffic superintendent; Mr. C. R. Fisher, district

Digitized by Google

plant superintendent; Mr. C. W. Frey, general wire chief; Mr. G. R. Alger, chief operator. The officers of the Club are: Mr. G. R. Alger, president; Mr. G. A. Putnam, vice-president; Mr. A. Turner, secretary and Miss L. M. Hood, treasurer. Committees—Arrangement: Albert Turner, Joseph E. Dunlap, J. F. McCarren. Executive: C. W. Frey, W. J. Armstrong, H. G. Gosting, E. H. Moore, C. W. Crary, J. J. McCruden. Reception: W. J. Armstrong, R. H. Bohle, W. J. Dill, T. F. Dunn, L. M. Hood, C. W. Jost, D. McFarland, C. McNeill, P. A. Peterson, P. W. Robertson, W. L. Rhodes, G. F. Stewart.

Mr. C. W. Groos, has been assigned to the night repeater service.

Mr. B. H. Arter, late of the Telepost Company, is being broken in at the main switchboard.

Chief operator G. R. Alger has just returned from a vacation to Chicago and nearby lake resorts. He was accompanied by his wife.

Miss Alice Coyle, operator on the St. Louis-Detroit circuit, and Mr. Hal. Coffee, Postal operator, were married at St. Charles, on July 29. They expect to make their home in St. Louis after October 1.

Mr. G. A. Riber, quad chief of the Chicago Division, is away on his vacation and Mr. C. A. Clark is filling the vacancy.

Mr. L. N. Boone, assistant wire chief, a veteran employe, is still confined to his bed at the hospital.

Mr. C. C. Dubbs, late of the night repeater force, has been assigned to similar day service.

Prosperity of the Serial Building Loan and Savings Institution.

The fifty-third semi-annual statement of the Serial Building Loan & Savings Institution of New York for the six months ended June 30 shows the Institution to be in a very prosperous condition. In his report to the members, president A. G. Saylor says that "the first half of the year 1911 has been one of the most prosperous in the history of the association, which has already gained more new members in six months of this year than in any full year since that in which the association was organized."

The institution is conducted for the express benefit of the employes of the telegraph and telephone service, and much credit is due to president Saylor and secretary E. F. Howell for the excellent results shown in the report. The board of directors, too, is deserving of great credit for their sound and wholesome advice in the conduct of the association's affairs, and for the giving of several hours of their valuable time each week to the institution's interests.

The great telegraphic song hit,
"SEND ME A NIGHT LETTER, DEARIE."
Good, catchy music; beautiful title design magnificently printed in colors. Title contains night letter. Sung all over New York, 17c. by mail. All popular music sent by mail.
B. L. BRANNAN,
195 B'way, N. Y.

New York Telegraphers' Aid Society Statement.

The New York Telegraphers' Aid Society's financial statement for the quarter ended June 6 shows:

Balance on hand March 6		$25,077.16
Receipts		1,933.00
Total		$27,010.16
DISBURSEMENTS.		
Sick benefits	$1,553.87	
Death benefits	500.00	
Expenses	214.86	$2,268.73
Balance on hand June 6		24,741.43
Total		$27,010.16
RELIEF FUND.		
Balance on hand March 6		$5,404.64
Receipts		126.07
Total		$5,530.71
Disbursements		$75.00
Balance on hand June 6		5,455.71
Total		$5,530.71

It is a valuable privilege to be eligible for membership in a sound and reliable life insurance association which cannot afterwards cancel or alter the terms of the certificate issued. The payment of the sum called for in a benefit certificate blesses alike the recipient and the provider. The Telegraphers' Mutual Benefit Association, 195 Broadway, New York, now the oldest co-operative life insurance association, having been in successful operation for the past 43 years, offers this privilege to all eligible employes of telegraph and telephone service. Write at once for application form and full particulars.

TRANSMITTING MACHINES

I am placing on the market improved YETMAN TRANSMITTING TYPEWRITERS, and KEYBOARD TRANSMITTERS without typewriting features. Am prepared to exchange, repair or rebuild all old machines. Write for catalogues and particulars to

James Uncles, NORTH ADAMS Massachusetts

Rubber Telegraph Key Knobs.

No operator who has had to use a hard key knob continuously should fail to possess one of these flexible rubber key caps, which fits snugly over the hard rubber key knob, forming an air cushion. They render the touch smooth and the manipulation of the key much easier. Price, fifteen cents.

J. B. Taltavall, TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

Every one engaged in telegraphy and telephony should be a constant reader of TELEGRAPH AND TELEPHONE AGE. It gives the latest news in both these fields. Subscribe now. Subscription price, $2.00 per year.

SOME POINTS ON ELECTRICITY.

BY WILLIS H. JONES.

SPECIAL FEATURES OF THE ATHEARN QUADRUPLEX.

Now that the new Athearn quadruplex is being generally installed in place of the old Western Union standard apparatus, there are several important features in connection with it that multiplex attendants should hasten to become familiar with, in order to avoid possible confusion in some cases and to derive the full benefit of all the additional facilities it offers in other situations.

We will first call particular attention to the alteration made in the local circuits. When the local battery switches are turned in the position required for connecting two different multiplex sets together in order that one may repeat into the other, a lamp resistance of about 100 ohms is simultaneously connected in the receiving side only. This method obviates the necessity for 100-ohm lamp compensating resistance being placed in the repeater cords at the loop-switch where the connections are made. Consequently, when two Athearn sets are to be thus connected, repeater cords must be provided which have no lamps in circuit.

Now during the period occupied in gradually making the numerous alterations in the system the quadruplex department obviously is called upon to handle both the old and the new apparatus, and in case of emergencies, is sometimes compelled to temporarily connect one type with the other. Under these circumstances it is obvious that neither the old nor the new repeater cords will answer the purpose, but the old ones with one lamp removed (the one in the receiving side conductor) will meet the requirement. Hence a third construction of repeater cord should be available until all multiplex sets are uniformly arranged.

Quadruplex attendants, therefore, should be careful when ordering such connections to inform the loopswitch chief what particular construction of repeater cord he shall use. This may easily be done by simply adding the word "new," "old," or "unlike," to his order. Unless a little precaution of this kind is exercised some delay may follow before the sets are properly connected. Otherwise the current will not be even on both sides.

Another special feature of the new quadruplex system is the addition of an extra double set of resistance coils, one for the main and the other for the artificial line, but which have no connection with the rheostat proper. This resistance is designated the "line resistance" and is looped in or out of both the main and the artificial line simultaneously by one movement of a double lever switch. It is needless to state that the value of the resistance in each set of coils thus inserted, or removed is identical, hence the home apparatus will not be thrown out of balance by any alterations made. The distant office, however, will require a new balance and for that reason should invariably be notified before making any change of this kind.

In order to appreciate the value of this addition to the multiplex equipment it is only necessary to call attention to the many relay coils that have formerly been burned out or partially injured on very wet days in the attempt to work quadruplex apparatus as duplexes with the long end closed. The excessive volume of current which resulted not only tended to destroy the insulation of the fine wire coils, but the unnecessary full value of electromotive force contributed to further increase the escape along the line.

The proper remedy under weather conditions of this kind is to provide a suitable voltage for the circuit. This value should obviously be greater than that of the "short end," and less than that of the "long end," hence it has heretofore been found advisable when possible to substitute a duplex set for the quadruplex apparatus temporarily in order to get between the two pressures.

Now the object of the extra resistance coils referred to is to provide a means of regulating the voltage and current to suit the weather conditions without being compelled to change sets or endanger the relay coils, and this is now all ac-

Digitized by Google

complished by one simple movement of the "line resistance" switch-lever, which action loops equal values of resistance in both main and artificial line just beyond the relay coils. The home apparatus is thus further protected by being somewhat removed, ohmically speaking, from the external circuit. The insertion of extra resistance in the line also tends to maintain a balance for a much greater length of time than would be possible without it for the reason that the ratio of the permanent, or set resistance, to that of the conductor, or external circuit proper, is thus made much greater. Hence the fluctuations in the value of current in the lesser or line resistance will be correspondingly diminished and therefore less effective.

It would be well for quadruplex attendants to take advantage of this facility whenever the escape on a wire becomes too great to quadruplex and the short end current is too feeble for duplex operation.

Mr. C. B. Turpin, manager of the Western Union Telegraph Company, Fresno, Cal., writes: "I like to get the AGE and the only regret I have in reading it is running across the back cover too soon, in each issue."

Personal.

Mr. William Marconi is now in Glace Bay, N. S., installing the duplex system of transatlantic wireless telegraphy.

Mr. S. Z. de Ferranti, a well-known English pioneer electrical engineer has arrived in New York and will spend about three weeks in this country.

Mr. William J. Smith, of the Western Union Telegraph Company, Seattle, Wash., was married to Miss Therese Schayer of Brooklyn, N. Y., August 28.

Lieutenant W. M. Lambdin, a well-known Texas telegraph operator, for many years in the government military service, has been appointed by President Taft to be Military Attaché to the Spanish legation at Madrid, Spain.

Mr. J. P. Spanier, representative of the Western Union Telegraph Company for Southern Europe, with headquarters at Naples, Italy, has been visiting London, England, for the past few weeks. He was accompanied by his wife.

Mr. T. Buckley, chief electrician Post and Telegraph Department, Wellington, New Zealand, having almost completed his investigations of the telegraph and telephone methods employed in the United States, will sail for London about September 15. He will make similar investigations in England and Europe, and return home in December.

Mr. Walter P. Phillips, a well-known old-time telegrapher and former general manager of the United Press and Associated Press was a recent New York visitor. Mr. Phillips is now connected with the Columbia Phonograph Company, Bridgeport, Conn.

Mr. J. H. Bell of the engineering department of the British post office, London, England, has been engaged by the Western Electric Company for service in New York. Mr. Bell was regarded as one of the brightest telegraph engineers in the service in England.

Mr. J. W. Laughlin of the United Fruit Company's electrical department, Port Limon, Costa Rica, is in New York visiting friends. Mr. Laughlin was formerly employed by C. G. Gates & Co., bankers and brokers in New York, and is well known to the telegraph fraternity.

Mr. A. S. Hibbard, of the personal staff of Mr. Theo. N. Vail, president of the American Telephone & Telegraph Company and of the Western Union Telegraph Company, has returned from a trip to England, where he spent several weeks investigating the telephone and telegraph situation in that country.

Mr. P. J. Feeney, a well-known telegrapher and for the past fourteen years manager in Bangor, Me., of the Vacuum Oil Company, has resigned to accept a position in the Boston office of the Griffin Wheel Company of Chicago. Mr. Feeney is held in high esteem in Bangor where he was

Digitized by Google

one of the most respected citizens, and has a host of friends.

Mr. J. Frank Howell, a former telegrapher, and now a successful stock broker in New York, publishes a weekly review of the financial market, besides other financial information. In the issue of August 26 he gives a short and interesting account of the career of Mr. Theo. N. Vail, president of the American Telephone and Telegraph Company and of the Western Union Telegraph Company. A portrait of Mr. Vail is also shown.

Mr. Edwin M. Kerr, president of the Westinghouse Electric and Manufacturing Company, Pittsburgh, Pa., was formerly a telegraph operator on the Kansas Pacific Railway. He was born May 3, 1860, and in 1881 he entered the Sheffield Scientific School of Yale and graduated in 1884. Mr. Kerr occupied various railroad positions after his graduation and became associated with the Westinghouse interests in 1898. In 1905 he was elected first vice-president of the company of which he now is the head.

Mr. Gano Dunn, a former telegrapher, who for some years has been first vice-president, chief engineer and a director of the Crocker-Wheeler Company, Ampere, N. J., has resigned from that company in order to accept an important engineering and executive position. Mr. Dunn will sail shortly for Europe to attend, as president of the American Institute of Electrical Engineers, the meeting during the Turin Exposition of the International Electrotechnical Commission, to be held on September 7, 8 and 9, and also the following meeting of the International Electrical Congress.

Mr. Jerry L. Newton, manager of the San Antonio, Tex., office of the Western Union Telegraph Company, has retired from active duties after a continuous service of forty-three years. He was a prominent figure in San Antonio's business interests, and has been closely identified with the growth of that city. When he went there two operators were employed in the office. Now there are forty. Mr. Newton has a poetic vein in his nature and is the author of many poems of considerable merit. His numerous friends wish him peace and happiness in his retirement from the world of activity and many years more of health and life.

Mr. John E. Wilkie, head of the United States Customs agents, is an old operator, and attained his present position of importance through his resourcefulness and achievements in the secret service. He was at one time a reporter for the Chicago *Tribune*, and learned telegraphy while covering night police and fire headquarters news for his paper. He, in conjunction with John P. Barrett, city electrician of Chicago, designed the first police patrol call box signal system used in that city. His work in the secret service brought him to the high regard of government officials at Washington, and his latest reward is his promotion to head the United States Customs agents in addition to his secret service duties.

Postal Telegraph-Cable Company.

EXECUTIVE OFFICES.

Mr. C. C. Adams, second vice-president, New York, has sailed for Paris to join his family who have been traveling in Germany and Austria during the summer.

Mr. Theo. L. Cuyler, Jr., assistant treasurer, New York, has returned to his office after an extended leave of absence, greatly benefited in health.

Mr. E. Kimmey, district superintendent, is taking a few weeks' rest.

Mr. M. M. Davis, electrical engineer, New York, is spending his vacation on Long Island.

Mr. E. S. Butterfield, general agent of the money transfer service of this company, New York, has resigned his position and retired from active service.

Mr. M. Klepper has been appointed manager of the office at 1566 Broadway, New York, vice T. J. McQuillan resigned.

Mr. W. Y. Nolley, manager of the Mackay Telegraph and Cable Company, Dallas, Tex., was a recent executive office visitor. While in New York Mr. Nolley called on many of his old friends. Among other executive office visitors were P. J. Farrell, chief operator at Boston; Charles E. Stump, manager of the Dock street branch office, Philadelphia, Pa.; W. C. Lloyd, manager of the New Orleans, La., office, who was accompanied by Mrs. Lloyd.

Mr. J. S. Greever, manager at Chattanooga, Tenn., is spending his vacation in the North, visiting New York, Atlantic City, Philadelphia, Niagara Falls and Washington.

Mr. Warren S. Hallett has been appointed acting superintendent of supplies of this company, with headquarters at New York, vice W. D. Francis deceased. Mr. Hallett was born in Provincetown, Mass., December 20, 1868. In October, 1895, he entered the supply department of this company in New York, and has been employed in that branch of the service ever since, occupying positions as clerk, storekeeper and chief clerk. He filled the last named position at the time of his appointment as acting superintendent of supplies.

The Mackay Telegraph and Cable Company has been incorporated in Arkansas, with a capital stock of $10,000. The incorporators are F. W. Conger, C. T. Coffman and J. C. Marshall.

Death of W. D. Francis.

Walter D. Francis, superintendent of supplies, Postal Telegraph-Cable Company, New York, died of heart disease August 14 after an illness of several weeks. Deceased was born at Bath Beach, L. I., N. Y., August 26, 1862, and began his telegraphic career in 1879, when he entered the service of the Gold & Stock Telegraph Company as messenger. Later he was connected with other telegraph companies, and during the construction of the Postal company's lines to the Pacific Coast, Mr.

Digitized by Google

Francis received and distributed supplies and money in connection with that work. He was a man of quick perception and had a wide knowledge of accounting and was familiar with all the details pertaining to the purchasing and handling of telegraph material and supplies. He had a large capacity for work, and a remarkable memory, and these qualities, coupled with his honesty of character, admirably fitted him for the exacting duties of the position he occupied.

The funeral was held at the late home of the deceased in East Orange, N. J., August 16, and was attended by all of the officials of the company with which he was connected, as well as many of his other telegraph friends. Among those present were: E. J. Nally, C. C. Adams, C. P. Bruch, Geo. Clapperton, W. T. Capen, E. B. Pillsbury, L. Lemon, C. A. Lane, Edward Reynolds, John O. Stevens, Theo. L. Cuyler, Jr., W. B. Dunn, Isaac Smith, J. F. Skirrow, D. McNichol, F. E. McKiernan, J. H. Flood, E. T. Rice, J. Foley, H. J. McNamee, John Young, E. S. Butterfield, A. Kavanagh, J. Dennis, E. Fisk, W. J. Lehmer, H. Crawford, J. Koenig, Miss F. E. Mayo, Miss L. Cleveland, B. Ley, G. H. Nokes, J. Kale, W. S. Hallett, F. J. Kernan, C. H. Seymour, C. Shirley, J. T. Needham, J. Costelloe, J. F. Ellis, J. J. Cardona, J. B. Taltavall, M. J. O'Leary, Thomas E. Fleming, J. J. Ghegan, H. G. Pierson.

A most touching tribute of respect to the deceased and one that will live long in the memories of those who took part in it, was the forming of two lines composed of his associates and friends in life, headed by vice-president and general manager E. J. Nally and vice-presidents C. C. Adams and C. P. Bruch of the Postal company, and Geo. Clapperton of the Commercial Cable Company. With heads uncovered and with slow and solemn tread, on either side of the hearse containing the mortal remains of their dear departed friend, the mournful procession wended its way from his late home to the railway station. Interment was at Greenwood Cemetery, Brooklyn.

Western Union Telegraph Company.

EXECUTIVE OFFICES.

Mr. Theo. N. Vail, president of this company, is spending his vacation a few days at a time at his farm at Lyndonville, Vt.

Mr. Newcomb Carlton, vice-president, is absent on his vacation.

Mr. H. C. Worthen, general superintendent, Southern Division, Atlanta, Ga., announces the following rearrangement of district lines in that division: First district to comprise the States of Virginia, North Carolina and South Carolina; second district, the States of Georgia and Alabama; third district, the State of Florida; fourth district, the States of Tennessee, Kentucky and Mississippi.

Mr. R. W. Whitehead, division plant superintendent, Denver, Col., has been transferred to the like position in Chicago, vice M. H. Clapp now superintendent of telegraph Northern Pacific Railroad, St. Paul, Minn.

Mr. W. C. Titley, district plant superintendent, Chicago, Ill., has been advanced to the position of division plant superintendent at Denver, Col., vice R. W. Whitehead.

Mr. C. R. Fisher has been appointed district plant superintendent with headquarters at Denver, Col., vice Mr. J. H. Otey, transferred to the Western Division.

Mr. J. W. Rahde has been appointed division auditor of the Eastern Division with headquarters at New York, vice Mr. J. J. Clunan who is now special agent for the auditor's department.

Mr. C. A. Rhodes has been appointed division auditor of the Pacific Division of this company, with headquarters at San Francisco, Cal. Mr. Rhodes was formerly with the Postal Telegraph-Cable Company in New York.

Mr. Jacob Levin has been appointed special agent for the Southern Division, with headquarters at Atlanta, Ga.

Mr. F. H. Gournoe, special agent of the Gulf Division of this company, at Dallas, Tex., has been appointed manager of the San Antonio, Tex., office, vice J. L. Newton retired.

Mr. Rogers White has been appointed manager at Suffolk, Va., vice W. S. Green transferred to the operating department at Portsmouth, Va.

Mr. E. L. Spooner has been appointed manager at Wilmington, N. C., vice P. G. White resigned.

Mr. G. C. Cauthen has been appointed manager of the Washington, N. C., office, vice W. F. Clark resigned.

Mr. G. W. Phillips, formerly manager of the Postal Telegraph-Cable Company's office at Raleigh, N. C., has been appointed chief operator for this company at the same point.

Mr. C. H. Parsons, wire chief of the Rock Island system, at Goodland, Kan., has accepted the position of repeater chief of the Western Union Telegraph Company at Salt Lake City, Utah.

Mr. R. H. Brooks, of Memphis, Tenn., has accepted the position of late night chief at Little Rock, Ark.

Miss Carrie B. Beall, manager of the Portsmouth, Va., office of the Western Union Telegraph Company, is one of the most expert women operators in the service. She has been connected with the company for over fifteen years, and was at one time employed at Cincinnati. She was manager of the office at Fortress Monroe, Va., for several years and then went to Hot Springs, Va., as manager, afterwards going to Norfolk as operator. She resigned her Norfolk position to become manager at Portsmouth.

The Telephone.

The district plant office of the American Telephone and Telegraph Company at Philadelphia was transferred to New York September 1.

Mr. G. B. Bush has been appointed assistant general manager of the Pacific Telephone and Telegraph Company, San Francisco, Cal., vice Mr. P. H. Coolidge, who has been appointed general commercial superintendent, succeeding Mr. G. B. Bush.

Double-Loaded Telephone Cable.—A double-loaded telephone cable is to be laid between La Panne, in Belgium, and St. Margaret's Bay, England.

New Telephone Exchange for Spokane.—The Pacific Telephone and Telegraph Company will erect an eight-story steel and brick exchange building in Spokane, Wash.

International Telephony in Europe.—A bill sanctioning the provision of telephonic communication between Milan, Zürich, Basle, Frankfort and Berlin, has been passed by the Italian Parliament. The installation of the line will be a very important undertaking.

New Telephone Headquarters in Chicago.—A twenty-story building is being erected on the corner of Washington and Franklin streets, Chicago, for the new general headquarters for the five Bell telephone companies of the central group. It is expected to have the building ready for occupancy early in the summer of 1912.

In Memory of Telephone Pioneers.—The promoters of the association of "Telephone Pioneers of America," Messrs. Henry W. Pope, Chas. R. Truex and Thomas B. Doolittle, have established a custom of printing memorial sketches of deceased telephone pioneers. Thus far four have been issued: H. M. Watson, Frederick Allen, W. N. Eastabrook and W. D. Sargent.

Examination for Government Telephone Operator.—We have received from the United States Civil Service Commission, Washington, D. C., an announcement that an examination will be held on September 20 at various places throughout the country to secure eligibles for vacancies in the position of telephone switchboard operator in the departmental service at Washington. Application blanks may be secured of the United States Civil Service Commission, Washington, D. C.

The Telephone in Hamburg.—The central battery type of telephone switchboard has been in use in Hamburg, Germany, since July, 1910. An average of 800 lines are connected to each switchboard, and 14,000 more subscribers may be connected with the present equipment. There are now 40,000 telephones in use in the city at the present time, and it is proposed to increase the capacity of the equipment to accommodate 80,000 subscribers. This would be the extreme limit of capacity of the present telephone building.

Bell Telephone News.—The first number of *Bell Telephone News* has just appeared. It is published in Chicago and takes the place of the papers which were published separately by the five western telephone companies recently grouped together as one with Mr. B. E. Sunny, of Chicago, as president. The papers thus absorbed were the Chicago Operating Bulletin, the Wisconsin Telephone News, the Central Union News, the Cleveland Telephone News, and the Michigan State Gazette. Mr. Amory T. Irwin is editor.

New Book on Telephony.

A new book entitled "Modern American Telephony in All Its Branches," by Arthur Bessey Smith, will be ready for delivery in September. It will contain over 800 pages and nearly 600 illustrations, and will be the most complete and up-to-date work on the subject. The price will be $2.00 per copy. Address TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

Telephone Pioneers of America.

The first meeting of the Telephone Pioneers of America has been called to be held at Boston, Mass., November 2, 3 and 4.

President Theo. N. Vail and Prof. Alexander Graham Bell have signified their intention to be present and it is believed there will be a large attendance from all parts of the country. It was practically the unanimous vote of the pioneers to meet in Boston in view of its being the birthplace of the telephone.

Arrangements as to entertainment and meeting will be forwarded to the members later. Those contemplating attendance are requested to inform Messrs. Henry W. Pope, Charles R. Truex, and Thos. B. Doolittle, 15 Dey Street, New York, as promptly as possible.

The Cable.

Cables Affected by Earth Currents.—Recent earthquakes and terrestial magnetic disturbances caused considerable trouble in the operation of submarine cables

New Cable Between Russia and Sweden.—The Northern Telegraph Company has laid a new cable between Nystad, in Russia, and Grisslehaum, in Sweden. This is the third cable between these points, and is 123 miles in length.

Around the World in Sixteen and One-half Minutes.—On Sunday evening, August 20, the *New York Times* sent a telegraph message addressed to itself around the world, in order to ascertain the speed of a commercial dispatch on such a journey under normal conditions. The message was sent from the *Times* telegraph room at 7 o'clock, and at 7:16:30 it was received at the same

Digitized by Google

place, having travelled around the world in the meantime. The total distance covered by the message over land lines and submarine cables was 28,613 miles.

The message was handled as a purely commercial dispatch, without any preliminary arrangement for its speedy transmission. The route of the dispatch was from New York to San Francisco over the lines of the Postal Telegraph-Cable Company; San Francisco to Honolulu, Sandwich Islands, Midway Islands and Manila, via the Commercial Pacific Cable Company's lines; Manila to Hongkong, Saigon, Singapore, Madras by the Eastern Extension, Madras to Bombay by the Indian Government land lines, Bombay, Aden, Suez, Port Said, Alexandria, Malta, Gibraltar, Lisbon and the Azores by the Eastern Telegraph Company, and from the Azores to New York via the Commercial Cable Company.

It is stated that this is the fastest time ever achieved by a commercial dispatch around the world. Eleven years ago a dispatch was sent around the world on the occasion of the opening of the Commercial Pacific cable in nine minutes and thirty seconds, but preliminary arrangements were made for quick transit.

Canadian Notes.

Mr. W. J. Camp, electrical engineer Canadian Pacific Railway Telegraphs, Montreal, Que., has returned from his annual inspection trip to the Pacific Coast.

Mr. W. M. Thompson has been appointed manager of the Saskatoon, Sask., office of the same company and manager of the Winnipeg, Man., grain exchange office of the Canadian Pacific Railway Telegraphs.

Radio-Telegraphy.

Mr. A. F. Parkhurst has been appointed inspector for the United Fruit Company's wireless service for the New York, Boston and Philadelphia boats, with headquarters at 17 Battery Place, New York.

United Wireless Telegraph Company.—The receivers of the United Wireless Telegraph Company, New York, have made arrangements to continue the business.

Wireless Examinations. — The examination of wireless ship operators for certificates will be held at the Brooklyn Navy Yard at 10 a. m. Wednesdays hereafter instead of Tuesdays and Thursdays. Mr. W. H. F. Schluter, chief gunner, U. S. Navy, is the officer in charge of the electrical class.

Largest Wireless Station for Canal Celebration.—A feature of the Panama-Pacific Exposition, which will be held in San Francisco in 1915, will be the wireless telegraph station on Telegraph Hill in that city. It is planned to erect the largest station ever built, by means of which the passage of the fleet of battleships through the Panama canal can be continually signaled. The range will be about 4,000 miles.

Wireless in Alaska.—The Navy Department will erect a powerful wireless station on one of the Aleutian Islands, in Alaska, next year. It will have a radius of 1,500 miles at night and about 800 miles during the day. Wireless stations are now being established on Kadiak, Unalaska and St. Paul Islands, Alaska.

State Monopoly of Wireless in France.—Although the hour at mid-day is daily signalled throughout France from the Eiffel tower by wireless telegraphy, a recent decree of the Administration of Posts and Telegraphs forbids French clockmakers to set up receivers to regulate their clocks and watches. The reason for this is that the Administration claims the monopoly of working the system of wireless telegraphy. Much indignation is expressed over this action.

Transatlantic Wireless Telegraphy.—Under an agreement entered into by Marconi's Wireless Telegraph Company, Ltd., the Marconi Wireless Telegraph Company of Canada, Ltd., and the Marconi International Marine Communication Company, Ltd., on the one hand, and the Canadian Government on the other, says the *Marconigraph*, the Marconi companies undertake to transmit general messages between stations on the Atlantic coast of Canada and corresponding stations on the coast of Great Britain and Ireland, at not more than ten cents per word for such messages. Press messages will be transmitted at a shore-to-shore rate not exceeding five cents per word, and messages in connection with weather conditions and forecasts, tide conditions, ice, and reports on aids to navigation, will also be transmitted at that rate. The Montreal and Three Rivers stations pass into the possession of the government for a substantial consideration, and the Marconi companies undertake to maintain and operate the government-owned wireless stations in Newfoundland, Quebec, Nova Scotia and New Brunswick. This contract remains in force for 20 years.

Telegraph and Telephone Papers at Turin Electrical Congress.—The following papers on Telegraphy and Telephony will be read at the International Congress of the Applications of Electricity, to be held at Turin, Italy, September 10 to 17; "Long-distance Wire Telephony," by F. B. Jewett, of the United States; "Wireless Telephony," by Valdemar Poulsen, of Denmark; "Automatic Telephone Exchanges As a Means of Economy and Improvement in Telephonic Communication in Large Cities," by H. Milon, of France; "Research on Secrecy in Wireless Telegraphy," by P. O. Pedersen, of Denmark.

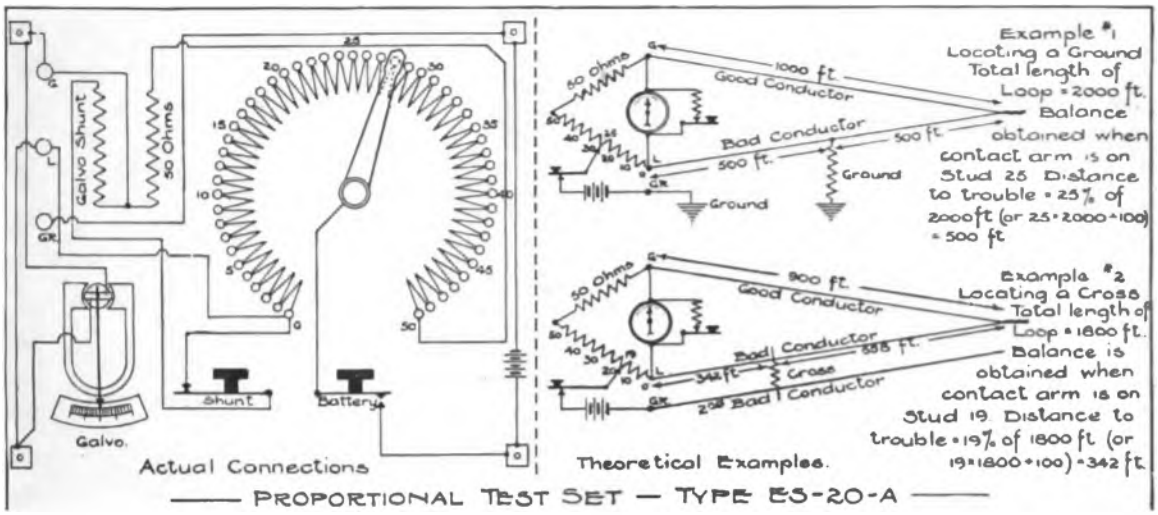
Proportional Test Set.

The accompanying illustration shows the connections of an instrument devised by the engineer of equipment of the Western Union Telegraph Company for locating cable troubles. It is officially designated a Proportional Test Set, and is described in the *Journal of the Telegraph*. It is intended for the use of linemen and others who maintain sections of the company's cables. It consists of a simplified rheostat, galvanometer and battery contained in box 7 in. x 9 in. x 5 in. in size. By its use accurate locations of faults on cable conductors may be readily made.

The diagram at the left shows the relative positions of the component parts of the apparatus and the connections between them, and that on the left shows theoretical examples of tests.



DIAGRAMS OF PROPORTIONAL TEST SET.

The following instructions are given for the locating of a cross or ground:

Select a good conductor of the same gauge as the faulty conductor, preferably one running in the same route and in the same cable. Connect the good conductor to binding post "G" of the test set, and the faulty conductor to binding post "L." Connect the distant ends of the good conductor and the faulty conductor together.

If the trouble is a cross, connect the other crossed conductor to binding post "GR." If the trouble is a ground, connect a ground wire to binding post "GR."

Move the arm over the studs around the circle until a position is found where pressing the battery key does not move the needle. Now press both "Shunt" and "Battery" keys and if the needle moves, find the stud at which the needle has the least movement.

Multiply the number of this stud by the total length in feet of the loop, and divide by 100; this will give the distance in feet from the test set to the trouble. The total length of the loop is the length of the good conductor added to the length of the faulty conductor.

The small lever near binding post "L" is to be used only for centering the galvanometer when necessary before the test is started.

Self-Adjusting Relays and Resonators.

BY C. E. McCLUER, NORFOLK, VA.

Referring to the articles on "Self-Adjusting Relays," by Willis H. Jones, and "Resonators," by J. S. Knapp, in the July 16 issue of TELEGRAPH AND TELEPHONE AGE, some fifteen or twenty years ago I got the "self-adjusting relay" bug in my bonnet, and spent some time studying and experimenting in that direction. My unfortunate and trying experiences with the ordinary railway "hams" during wet weather, had taught me the pressing need for some such device.

My extended experience with the telephone had suggested the possibility of utilizing the principle underlying the operation of the telephone, in lieu of both the telegraph relay and sounder, reducing materially and simultaneously the strength of current necessary to be used on the wires, and the noise of the sounders. I worked for some time on the theory that the susceptibility of the telephone to the influences of even the weakest battery current might be availed of to insure the reception of the Morse signals over heavy "escapes" without interfering in any way with the pulsations of the stronger currents that came over the wire when the circuit was broken at a nearby office. In other words, I thought that perhaps the telephone would make a good telegraph receiver that would on a standard adjustment invariably respond to signals transmitted over either a well insulated or a leaky wire, or to weak or strong currents. The solution of the problem lay, I thought, in the proper adjustment of the dimensions, form and weight of the various elements that go to make up the telephone, but after playing all the variations possible, without achieving success, I finally abandoned the effort

Digitized by Google

and settled down into the conviction that the idea was impracticable.

My son, who was aiding me in the experiments, then constructed a "midget" sounder and enclosed it in a light aluminum case to be fitted directly to the ear of the operator after the manner of the telephone operators' head-telephones. It could be as easily worn over the ear as the ordinary head-telephone, and without any more discomfort or fatigue. While the noise of the "midget" sounder could be reduced to any extent desirable, even to the minute noise of a closely adjusted relay armature, its close proximity to the drum of the ear enabled it to be heard clearly and distinctly. The provision of an adjustable tension to the retractible spring which could be manipulated without removing the sounder from the ear, made of it as practicable a telegraph receiver as the ordinary relay, while it was held securely to the ear by the usual head-telephone strap-springs. A few simple tests impressed us with the conviction that the problem I had originally attacked had been pretty well solved, but neither of us being connected with the telegraph interests at the time, we did not have an opportunity for crucial tests, and finally laid the device aside and forgot all about it.

When after about thirty-five years' absence I recently returned to the telegraph key as a means of livelihood, the telegraph equipment of my office consisted of a "main circuit sounder" and a key. In order to get distant offices during wet weather I was compelled to adjust the armature of the sounder closely, which reduced the noise of the armature so that I could not hear it when copying on my typewriter. This naturally caused my mind to revert to the old idea of the "midget" head-sounder. I hunted up the experimental instrument of fifteen or twenty years before, and putting it in commission I was pleased to find that it filled the bill completely, and I have been using it ever since to the entire exclusion of the main circuit sounder.

My idea is that such an instrument might be made to take the place of both the ordinary relay and sounder as a means of receiving telegraphic signals; "call" or "signal" bells being utilized instead for calling offices. On through or busy wires, there would ordinarily be no need for special signaling apparatus, as the operators working such circuits would supposedly be constantly at their keys with the head sounders to their ears. On "way" or railway wires, some means of signaling would be necessary, and bells of various character and tones could be adopted in lieu of the present sounders, probably to the manifest advantage of the service.

Fancy a large telegraph operating room like that of the main New York office of the Western Union Company equipped with a complete outfit of such midget head-sounders. It would be so much easier for an operator to concentrate his thoughts and attention on the minute ticking of his midget head sounder, that I feel quite sure all operators would give their unqualified approval to its introduction, once they had become accustomed to it. Each operator should have his individual "midget" so adjusted as to intensity of sound as to suit his individual requirements or fancy, and with a double flexible cord and plug constantly connected to it, so he could transfer his head receiver from one wire or table to another at will, each table being equipped with a spring-jack for the reception of the receiver plugs, just as telephone operators and their headphones are transferred from one section of switchboard to another.

Annual Meeting of Marconi's Wireless Company.

At the annual meeting of Marconi's Wireless Telegraph Company, held in London, July 20, Mr. William Marconi made an interesting report of progress. He stated that the transatlantic service continues to work very satisfactorily. Some trouble is experienced owing to the mutilation of code words by the land lines, more on the English lines than the American. A satisfactory solution of this trouble would be the continuance of the wireless service into London, provided the necessary license can be obtained from the post office.

He referred to arrangements now being made to introduce the new duplex system of wireless between Clifden station, Ireland, and the Glace Bay, N. S., station.

[Mr. Marconi is now at the latter station in connection with the work.]

The Coltano, Italy, station will be inaugurated this fall and will enable communication to be carried on between Italy and North America, and probably also with Great Britain, Spain, Turkey and Greece.

A press agency has been organized on the high seas, he stated, enabling the company to receive and distribute any news of importance occurring on shipboard or coming within the knowledge of ships upon the ocean.

A dividend at the rate of £7 per cent. per annum on the capital paid up on December 31, 1900, and an interim dividend at the same rate on the capital paid up June 30, 1911, and on the cumulative participating preference shares, was declared, payable September 1.

Making Trouble for Telegraph Companies.—In looking about for ways to make trouble for telegraph companies many curious things are revealed The Hutchison, Kan., *News* says: "It's against the law to shoot off firecrackers inside the city limits. And yet at the telegraph offices every time there is much of a thunder storm, there are firecrackers shot off that would tickle the small boy into ecstasy. They are the fuses on the switchboards, and when they 'blow out' they shoot just as firecrackers would. During the recent electric storm a score of them shot off with loud bangs."

The Effects of Sunlight on the Transmission of Wireless Signals.*

BY B. L. DOLBEAR AND J. A. PROCTOR.

Since the early days of wireless telegraphy it has been well known that the night is a much more favorable time than day for the reception of signals from stations over 150 miles distant. The difference between day and night intensity is not measurable at 100 miles, but at greater distances the night intensity is often as great as 100 times that of the day. Besides this day-night difference, another interesting phenomenon presents itself, namely, the rapid change of energy received from moment to moment. An inaudible signal will often be multiplied to 100 times audibility within the space of a few seconds; sometimes it remains so for several moments, sometimes for only a few seconds, but eventually disappears as suddenly as it appeared. This phenomenon is called "swinging," and while formerly it was thought to be due somewhat to local conditions at the transmitting station, it is now explained by the constantly changing conditions of the atmosphere, which vary the percentage of atmospheric absorption of the incoming signals. The reason why "swinging" is hardly noticeable at distances under 100 miles may be attributed to the fact that any marked changes in percentage of ionization due to irregularity of the sun's emission probably take place at quite an appreciable altitude. Hence, only the wave-fronts which have traveled some distance (probably corresponding to the minimum distances at which "swinging" is noticed) and which have reached an altitude which includes the ionized portion will be subject to absorption or loss of energy.

Until recently no data have been published showing definite measurements of the relative intensity at different times of day and night. At Amesbury, Mass., in 1909, Mr. Greenleaf W. Pickard carried on a series of measurements on intensity of signals as received from the Marconi transatlantic station at Glace Bay, Cape Breton. This station is about 700 miles from Amesbury, and at the time Mr. Pickard took his readings the radiating wave length was approximately 4,000 meters. A curve representing the results of Mr. Pickard's measurements show that the normal night-time intensity is between thirty and forty times that of the normal daytime intensity.

Last March the authors carried on another series of similar observations of the Glace Bay station signals as received at Revere and Somerville, Mass., each place about four miles from Boston. These observations covered six entire days within a period of two weeks, and on some of the days simultaneous measurements were made at both stations. As the stations at Revere and Somerville are only five miles apart, it would be supposed that the relative energy received at each station would be the same, which proved to be true as curves taken simultaneously check each other very satisfactorily. The most striking feature of these curves however is the effect of sunrise and sunset on the intensity of signals. In the early days of wireless telegraphy Marconi noted a difficulty in communicating over long distances at sunrise and sunset during the experiments in transatlantic communication carried on between the steamship *Philadelphia* and Poldhu, England. Mr. Pickard's curves of 1909 show a slight dip, at these times, especially at sunrise. He found the point of lowest intensity about midway between sunrise time at Glace Bay and sunrise time at Amesbury. It is interesting to note however that the points of minimum intensity shown in Mr. Pickard's curves occur at sunrise at Glace Bay and sunset at Boston.

A slight rise of intensity between noon and mid-afternoon takes place as shown by curves. Corresponding to this between midnight and 2 a.m. there is almost sure to be a sharp rise, followed by a gradual decline, until shortly before sunrise at Glace Bay. Just before taking the plunge preceding, and again at the recovery of intensity after sunrise and sunset, there is usually a quick oscillation of intensity. Besides this single fluctuation there are often others preceding and following it. Another noticeable feature is the relative width of the sunrise and sunset depressions, the latter always being the broader. The minimum points of intensity will generally be found to lag behind the actual sunrise or sunset time by some five minutes. The recovery of intensity after sunrise is perhaps the most surprising feature. In one case this recovery represented the maximum intensity for the whole twenty-four hours.

It seems impossible with the meager data on hand to give a fully satisfactory explanation of these various features. It has been suggested by some that the low daytime intensity is due to ionization of the atmosphere by the sunlight, which causes a dissipation of energy by conduction in the space between the transmitting and receiving stations. This appears to explain in a general way the phenomenon, but when it is considered that only the ultra-violet component of the sunlight produces ionization to any degree, and that these ultra-violet rays penetrate only a short distance into the atmosphere, it becomes evident that only the higher altitudes of the air are ionized, and this should not effect that portion of the wave traveling below this stratum unless it be proved that there is an upward passage of energy to compensate for the conduction losses. Neither does ionization satisfactorily explain the recovery of intensity after sunrise or before sunset. However, this sunrise-sunset effect may be due to entirely different causes and the ionization may be responsible for the effects which take place between sunrise and sunset.

Others have contended that the upper stratum

*From "Electrical World."

Digitized by Google

of ionized air may reflect the electromagnetic waves. However, as a definite line or surface of division must exist between substances having different physical properties in order that reflection may take place, this theory does not seem possible. There are no reasons to suppose that such a line exists under the ionized stratum. Fleming has pointed out that there may be a gradual refraction upward of the wave front, which might produce distortion of the wave.

If it were known that there was such a thing as interference between ether waves traveling in the same plane, a possible explanation of the sunrise-sunset effect might be given, but as two rays of light may be made to cross each other at any angle without the slightest displacement or refraction it hardly seems likely that any such action could take place with the electromagnetic waves.

An attempt was made to obtain information regarding possible changes of transmitting conditions at Glace Bay, such as variation of power transmitted at different times of day, but without success up to the time this article was written. The method employed in obtaining these readings is that of shunting the signals in the telephones to an audibility of unity. This is done by connecting a simple resistance box across the telephone terminals and by manipulating the plugs till a value of resistance is found at which the shunted signal is just audible. The greater the incoming energy at the receiving station, the louder the signal, and hence the less the shunt resistance required to reduce it to an audibility of unity. From resistance-audibility curves drawn for the particular telephone used, the value of audibility may be scaled, given a shunt resistance. With a little practice such readings may be confined within 10 per cent error, as shown when checked by galvanometer.

In taking such readings it is, of course, necessary that all inductances, capacities, couplings and adjustments should remain fixed and constant throughout the test. Once adjusted the inductance, capacity and inductive couplings will remain so unless intentionally changed, but the detector is subject to loss of adjustment from strong atmospheric disturbances and sometimes from slight mechanical jars. To retain equal sensitiveness at each adjustment a different method was employed at each station.

At Somerville a low-voltage 60-cycle current was employed in connection with a galvanometer. It is known that the efficiency of a detector of the solid rectifier type, such as is used in radio-telegraphy is independent of the frequency used. When an alternating emf of a few hundredths of a volt is impressed on the detector circuit, and a galvanometer is connected in place of the telephones, a maximum deflection of the galvanometer, obtained by adjusting the detector, indicates maximum efficiency of rectification. The galvanometer and source of supply may then be cut out and the telephones replaced ready for reception of signals.

At Revere a simpler yet very reliable method was used employing a special form of test buzzer with platinum contacts. Across the contacts of the buzzer was connected a condenser of about 0.5 microfarad in series with a single turn of inductance, thereby producing an oscillatory circuit. This loop of wire was placed some four feet from the receiving oscillation transformer, and at such an angle that with the buzzer in operation the oscillations set up in the loop of wire were just audible when the detector was adjusted to its highest point of sensitiveness. It is known that there is a limiting point of sensitiveness to every detector, and it is on this adjustment only that the buzzer is heard. The buzzer should, of course, be carefully muffled in some sound-proof material. The solid rectifier used in these observations was that combination of zincite and bornite known as the "perikon" detector.

The value of resistance corresponding to a given value of audibility depends upon the telephones used—that is, upon their impedance. The current divides at the shunt according to the impedance of the two circuits. The impedance of the telephones used in these tests was approximately 10,000 ohms to the detector currents, while the impedance of the shunt resistance, being non-inductive, is its true resistance. Thus a signal just audible with a 10,000 ohm shunt indicates an actual audibility of two; with a shunt of 5,000 ohms the audibility is three, etc. A curve showing the relation of audibility to resistance offers a means of rapidly ascertaining audibility from shunt readings. A better method is that of constructing a resistance box with a dial switch graduated to read directly in terms of audibility.

Benkö Primary Battery.—Mr. Stephan Benkö, an engineer of Budapest, Hungary, recently invented a new form of primary battery. The battery depends essentially upon the use of a porous carbon electrode in the form of a pot (open at the top) which is surrounded by a closed lead shell. The electrolyte, a bichromate solution, is fed into this shell under a suitable head to give a flow of ½ litre, or more, per hour per cell. It passes through the carbon to the zinc, whence it is removed by an overflow pipe. Polarization is thus reduced to a minimum and remains constant for a given current, provided the cell is not overloaded. The size of cell referred to is 9¼ inches high overall, 6¼ inches long and 1¾ inches wide; it weighs about 10 lbs., excluding the tank for electrolyte, and will give a steady current, depending upon the strength of the electrolyte and rate of flow, up to, say, 25 amperes, at 1.5 volts. The internal resistance is below 0.01 ohm.

CHANGES OF ADDRESS.—In ordering a change of address the old as well as the new address must be given.
REMITTANCES to Telegraph and Telephone Age should be made invariably by draft on New York, postal or express money-order, and never by cash loosely enclosed in an envelope. By the latter method money is liable to be lost, and if so remitted is at the risk of the sender.

September 1, 1911.

The Combination of Telegraph and Telephone.

That the telegraph and the telephone, as public utilities, are closely related, is generally conceded, and while either one can exist without the other, yet, worked in combination they form a service that is highly advantageous to the public. The telephone, although a more recent invention has a greater popular use than the telegraph simply because it requires no special training to operate it, as does the telegraph; and the fact that it is possible to talk direct with the person one wishes to communicate with is a feature not possessed by the telegraph, where a message is handled by at least two intermediaries. In the public mind, too, more or less mystery is associated with the telegraph, while with the telephone the reverse is true. The people are now beginning to know more about the telegraph through its co-operation with the telephone, and they will certainly use the combined service more and more as they learn the advantages offered by it.

The problem the operating company has to solve is to familiarize the public with the advantages offered by the co-operation of the two services and this it is doing in a very satisfactory manner by means of active canvassing and advertising, and it is gratifying to know that the public is showing its appreciation of the advantages of the combined service by utilizing it with growing freedom.

The technical and mechanical aspects of the problem of combining the telegraph and telephone are of a unique character, but they are being met by true engineering skill, and are being worked out on the assumption that what is thinkable within reason is possible of execution. The thing to do is to find out how, and there is where engineering skill enters the problem. The telegraph is operated most economically by the use of a single wire grounded at both ends, while the telephone requires two wires for satisfactory service. As far as the physical advantages resulting from the combination of the telephone with the telegraph are concerned the telegraph seems to be the gainer. One of these advantages is the interchange of wires; the telegraph calls upon the telephone for wires and vice versa, as necessity arises. The advantages the telegraph has over the telephone in such exchange of circuits is that the telegraph has a great many iron wires which are of no practical utility for telephone purposes, while all the telephone wires are of copper. It is, of course, not to be inferred from this that the telegraph has no copper lines. As a matter of fact it has a great many of them and uses nothing but copper in new work, therefore, these are interchangeable for telephone purposes in case of necessity.

This interchangeability of lines gives both of the companies a great advantage and places each in a position where any abnormal rush of business can be handled promptly, because each can call upon the other for the use of extra wires in the event of shortage in its own facilities.

The co-operation of the telegraph and the telephone seems to offer a solution of the problem that has always vexed the telegraph companies—that of maintaining non-paying offices. There are many instances where telegraph offices are kept open at a loss for the accommodation of the public. Obviously a distinct advantage would be gained by the operating company and the public alike, by closing the unprofitable telegraph offices and sending the telegraph business by telephone to the nearest telegraph office. Indeed this has already been done in some localities and it is stated is giving general satisfaction.

The ultimate success of the combination of the telegraph and the telephone as a public utility depends largely upon the education of the people to the advantages of this service. The telephone is almost as much of a household necessity as is sugar, and a great part of the public is as familiar with it as it is with any other article of household necessity. The popularity of the telephone is no doubt due almost entirely to the systematic business campaign of the telephone companies whose agents go into the homes of the people and explain the great advantages resulting from having an instrument on the premises.

The telegraph of itself, of course, could not be made popular in the same sense because it requires training to operate it, but by means of a telephone its utility can be and is being immensely increased. The combination produces possibilities of great practical value. Every connected telephone is virtually a telegraph office, and if a person on a farm for instance, several miles from a telegraph office, wishes to send a telegram to, say, San Francisco or even London or China, he

Digitized by Google

need not hitch up to drive to the telegraph office. All that is required of him is to telephone his message from his home to the nearest telegraph office and the telegraph company will do the rest. This all seems very simple now to those who understand the process, but there are thousands of persons throughout the country who as yet know nothing of this great practical public service utility available and it is the object of the telegraph companies to reach as many of these persons as possible by the publicity campaign that it is now conducting. It is simply a question of education and that success will be the outcome there can be no reasonable doubt.

Old Timers at Atlantic City.

The reunion of the Old Time Telegraphers' and Historical Association and the Society of the United States Military Telegraph Corps, which is to be held at Atlantic City, N. J., September 5, 6 and 7, promises to be the most successful ever held by the two organizations. A large attendance is looked for and several distinguished gentlemen have been invited to be present.

Atlantic City seems to be the nation's choice as a convention and holiday city. Many of the large associations meet here regularly every year, and the attractions of the resort are so luring that many other bodies give the place the preference for their meetings. The sea air which one breathes is invigorating and the crowds of pleasure seekers give Atlantic City a charm that is hard to resist.

Lessons in Failures.

An important lesson may be learned from some of the results of the examinations of wireless ship operators at the Brooklyn Navy Yard. Under the new law, which took effect July 1, among other things, operators must know how to manage wireless apparatus under extraordinary circumstances. In case of a breakdown, for instance, they must know how to make repairs and put the apparatus in an operative condition. The ability to do this requires a slight technical knowledge, yet some aspirants to positions as wireless operators on ships seem to have the idea that all that is required of them is to be an operator. The question as to who else on a ship could be called upon to restore the apparatus to workable order in the event of breakdown does not seem to have entered their minds, yet this is the crucial test of the examinations.

Those applicants rejected at the examination failed because they were not familiar with the apparatus, and yet it is gratifying to note that of the total number of applicants for certificates the percentage of failures was small. The lesson in these failures is that all wireless, land, or cable operators should increase their knowledge of the work they are engaged in and fit themselves for extraordinary duties and emergencies.

Substitute for Platinum. — It is stated that a manufacturing jeweler of Elizabeth, N. J., has invented and patented a platinum alloy which he claims can be used as a substitute for pure platinum for many purposes, and costs about 3% of the price of the pure metal.

An Arraignment of Men.—A president of one of the great telephone companies states that women are neater than men, and steadier than men. He has 6,000 women in his employ and says that men as a general thing cannot do telephone switchboard work. They are lazy and impertinent and women are to be preferred, as they are more polite and efficient.

Wireless Officials to Prison.—Col. C. C. Wilson, F. X. Butler and W. W. Tompkins, president, counsel and selling agent respectively of the United Wireless Telegraph Company, New York, were, on August 22, taken to the Federal prison at Atlanta, Ga., where they will serve their terms of imprisonment for using the United States mails to defraud, in connection with the sale of wireless stock. Wilson will serve three years, Butler two years and Tompkins one year.

Dallas, Tex., as a Telegraph Center. — Since the establishment of the headquarters of the new division of the Mackay Telegraph and Cable Company at Dallas, Tex., that city probably becomes the third most important telegraph center in the United States. The executive offices of the Postal Telegraph-Cable Company of Texas are located in that city, while it is the divisional headquarters for the Western Union Telegraph Company and for the Mackay Telegraph and Cable Company, as well as being the executive headquarters for the Southwestern Telegraph and Telephone Company.

The Turner Monument Fund.

Work on the monument which is to be erected at Harriman, N. Y., this fall to commemorate the sending of the first telegraph train order, is going forward, and preparations will soon be made for the ceremonies to be held at the unveiling. Mr. Charles Keck, of New York, the sculptor, is making rapid progress in the cutting work and a very handsome monument will be the result.

There is yet an opportunity to subscribe to the monument fund, and those who have not yet done so are urged to send their contributions as early as possible to the treasurer of the fund, Mr. J. B. Taltavall, 253 Broadway, New York. Acknowledgments are made in the columns of TELEGRAPH AND TELEPHONE AGE.

While the fund is practically closed, this notice is intended for those who wish to be identified with this worthy movement and have their names included among those of the other contributors.

The total amount received up to date is $1,653.25.

The "73" Ball Team of Portland, Ore.

The accompanying illustration represents the baseball team composed of employes of the commercial department of the Western Union Telegraph Company at Portland, Ore., and said to be one of the fastest amateur teams in that State. They call themselves the "73's" and the excellence of their playing has brought them many favorable newspaper notices.

THE "73" BASE BALL TEAM OF PORTLAND, ORE.

The team has visited various cities in the State during the present season, and has played an excellent game, the net results being strongly in their favor, and the telegraph people in Portland are proud of the record established by their team.

A Point on Repeater Adjustment.

BY C. L. HIGGINS, CHEYENNE, WYO.

I have often searched for some treatise on the handling of repeating apparatus but always without success, although there are many available books containing diagrams. I will give some facts which I picked up several years ago hoping that the information may be of general benefit.

In case of a "kick" in a set of Milliken, Atkinson, Weiny-Phillips, or any other standard form of repeater, it may be tested out by first opening the key on, say the West side, and slowly tapping the lever of the West relay with the hand. If the "kick" is noticed while doing this observe whether it comes when you close the relay points, or when you open them; if the former, it indicates that the relay on the East side does not magnetize quickly enough to catch the lever of the transmitter when it is released by the holding magnets, repeating sounder, or other contrivance for holding the transmitter closed when the West side is open. The kick may be eliminated by moving the magnets of the relay closer to the armature by means of the yoke adjusting screw. Should the kick appear when the relay lever is released, it indicates that the holding magnets, repeating sounder, or other device used for holding the East line closed, does not operate quickly enough to perform its functions when the West side is opened. The kick may then be eliminated by tightening the spring, or raising the armature of the repeating sounder, in case of the Atkinson apparatus; moving the holding-magnet a little closer to the armature in the case of the Weiny-Phillips; either tightening the spring to the holding magnets or moving the holding-magnets away from the armature in case of the Milliken or other repeaters, whichever will cause the holding device to act more quickly. By far the greater number of troubles will be found to be due to the causes which produce the kick on closing the relay.

If there is no kick when tapping or writing on the West side reverse the operation opening the East key and tapping slowly on the East relay, making any of the mentioned changes on the West side of the set.

Much of the trouble in the handling of re-

Digitized by Google

peaters by inexperienced operators and beginners would be avoided if they would bear in mind that nine-tenths of the trouble with repeaters, after they are once in working order, is caused by weather conditions. These should be met merely by the use of the yoke adjusting screws, moving the relay magnets backward or forward as the case may require; whereas the changing of other adjustments will not only not help the trouble, but is likely to throw the entire apparatus out of adjustment and render it useless.

I might add that all relays should be adjusted by means of the yoke screw, which moves the magnets back and forth. The tensile spring should never be used except in cases of emergency, and then only by an experienced person.

QUESTIONS TO BE ANSWERED.

[The success which has attended our plan of publishing in each issue a list of questions covering the subjects considered in Jones' Diagrams, has encouraged us to maintain the work through other books. Students of telegraphy throughout the country are finding these questions of great assistance in their studies of the general principles underlying the operation of the apparatus with which they come in daily contact. Many consider this the best plan which has yet been devised for a systematic study of the technical side of the telegraph. Having completely covered Mr. Jones' book we are now covering "The Quadruplex," by Maver and Davis, and will bring out, in a like manner, all the facts that every telegrapher should know about duplex and quadruplex telegraphy as found in this book.]

CHAPTER VIII (*Continued*).

If ten wires of the same resistance and gauge are connected to one battery, in what proportion will the current distribute itself between the wires?

State the law relating to the distribution of current between several conductors joined to one source of supply.

If one circuit is divided into two branches of twelve ohms and six ohms, what proportion of the current will each branch take and what will be the joint resistance?

Why does the circuit of six ohms take more current than the one of twelve ohms?

Is the total resistance of two routes different to the resistance of either one of them? If so, state the reasons therefor.

What is the name given to express the total resistance of two or more lines joined together and receiving current from the same source?

What is the rule for calculating joint resistance?

[This rule should be studied carefully and memorized, as it is an important one.]

How is the strength of the current in a circuit ascertained?

State Ohm's law. [This law, or rule, should be carefully studied and memorized as it is of great importance.]

Calculate the joint resistance of two wires having (1) six ohms each, (2) six and twelve ohms, and (3) three and nine ohms.

What is a volt?

What is an ampere?

What is an ohm?

In the position of the transmitter shown in Fig. 34 trace the path of the current from the battery to the line.

How many paths are offered to the current at the point X?

What is the name of the resistance *C* placed between the post of the transmitter and the ground?

What is the effect upon the current from a given battery of increasing the resistance of the circuit through which the current flows?

Why are the transmitter connections not arranged to cut out the added resistance when that instrument is closed and leave it in circuit when the transmitter is open, thus dispensing with the "leak" circuit?

What was the reason for adding the "leak" to quadruplex circuits?

Referring to Fig. 34, how much resistance will a current from the distant station encounter at the home station after passing the point X?

In Fig. 35 what are the conditions met with by the incoming current?

How many routes are offered to an incoming current as shown in Fig. 35?

Is there any difference in the resistance opposed to an incoming current whether the home transmitters are open or closed?

Is there any definite relation between the various resistances shown in Figs. 34 and 35. If so, what is the purpose of preserving this relation?

Does increasing or decreasing the working current vary the proportions of current flowing in the branches of a divided circuit?

(To Be Continued.)

New Books.

Elementary Telegraphy, by H. W. Pendry, New York, is a manual for students and was written especially to meet the requirements of the ordinary grade of the subject as published in the syllabus of the City and Guilds of London Institute. While the work is written from an English standpoint, as far as the practice of telegraphy is concerned, it contains much matter of general interest. The underlying principles of course are the same in any country, but in this instance they are set forth in a very clear manner. The American student of telegraphy will no doubt find this part of the book of special interest, as it explains many things that are not always stated very clearly in other books of like character.

The section devoted to telegraph instruments and practice will be of interest to those who care to look beyond the American shores in matters pertaining to telegraphy. It is well to know how things are done in other countries besides our own, and a study of this section will aid in broadening the mind.

International Association of Municipal Electricians.

The International Association of Municipal Electricians which will hold its next annual convention in Atlantic City, N. J., September 12-15, is now fifteen years old, having been organized in Brooklyn, N. Y., September 15, 1896, and this is the third time it has met in convention at Atlantic City.

As stated in the constitution, the object of the association "shall be the acquisition of experimental, statistical and scientific knowledge relating to the constitution, equipment and operation of fire and police telegraph, light, heat and power systems, and the diffusion of this knowledge among the members of this Association with the view of improving the service and reducing its cost; and the establishment and maintenance of a spirit of fraternity among its members."

There are two classes of members—active and associate. Active members consist of superintendents of fire and police telegraph systems and other persons having charge of or connected with municipal electrical departments. Associate members consist of manufacturers of and dealers in appliances and apparatus relating to fire and police telegraph systems.

The annual meetings have proved to be the source of much benefit to the municipalities represented by the members of the association and to the country at large through the information given out in the form of papers and discussions. These papers relate to matters of great importance to municipal electricians and their work, and are of the most practical kind, because they are prepared by practical men. The association is a vigorous one and is constantly enlarging its sphere of usefulness, and its third meeting at Atlantic City promises to be one of the most important ever held by the association, both as regards the quality of papers and attendance.

The meeting of this year was originally arranged to be held at St. Paul, Minn., but on account of the sad death of S. W. Manning, superintendent of fire alarm telegraph of St. Paul, and chairman of the executive committee of the association, who was killed by electric shock on July 19, it was decided, in respect to his memory, to hold the convention elsewhere and Atlantic City was decided upon as the place of meeting. A better choice could not have been made, as Atlantic City is easy of access and a pleasant place in which to spend a few days during the warm season.

The following is a list of the places of meeting and the officers of the association since its organization:

1896—Brooklyn, N. Y., Frank C. Mason, president; Morris W. Mead, vice-president; L. Lemon, secretary; Adam Bosch, treasurer.

1897—Nashville, Tenn., W. Y. Ellett, president; William Brophy, vice-president; H. F. Blackwell, Jr., secretary; Adam Bosch, treasurer.

1898—Elmira, N. Y., J. W. Aydon, president; G. F. Macdonald, vice-president; H. F. Blackwell, Jr., secretary; Adam Bosch, treasurer.

1899—Wilmington, Del., William Brophy, president; G. F. Macdonald, vice-president; H. F. Cottrell, secretary; Adam Bosch, treasurer.

1900—Pittsburgh, Pa., M. W. Mead, president; J. F. Zuluff, Burt McAllister and R. E. Moran, vice-presidents; F. P. Foster, secretary; Adam Bosch, treasurer.

1901—Niagara Falls, N. Y., A. S. Hatch, president; W. M. Petty, A. C. Farrand, Wm. Crane and Wm. A. Barnes, vice-presidents; F. P. Foster, secretary; Adam Bosch, treasurer.

1902—Richmond, Va., W. H. Thompson, president; Jerry Murphy, A. C. Farrand, W. A. Barnes, C. L. Williams, vice-presidents; F. P. Foster, secretary; Adam Bosch, treasurer.

1903—Atlantic City, N. J., A. C. Farrand, president; W. M. Petty, G. F. Macdonald, F. F. Pierson and F. A. Cambridge, vice-presidents; F. P. Foster, secretary; Adam Bosch, treasurer.

1904—St. Louis, Mo., Walter M. Petty, president; J. B. Yeakle, G. H. Holderman, C. E. Diehl and Charles Greenwald, vice-presidents; F. P. Foster, secretary; G. F. Macdonald, treasurer.

1905—Erie, Pa., Jerry Murphy, president; Wm. Crane, H. R. Allensworth, R. Blakey and F. A. Cambridge, vice-presidents; F. P. Foster, secretary; C. E. Diehl, treasurer.

1906—New Haven, Conn., T. C. O'Hearn, president; James Grant, Clarence R. George, John Berry and Wm. H. Bradt, vice-presidents; Frank P. Foster, secretary; C. E. Diehl, treasurer.

1907—Norfolk, Va., R. A. Smith, president; J. B. Yeakle, R. Blakey, C. F. Gall, Charles S. Downs, vice-presidents; F. P. Foster, secretary; C. E. Diehl, treasurer.

1908—Detroit, Mich., J. B. Yeakle, president; W. S. Devlin, H. C. Bundy, M. C. Cambridge and Clarence R. George, vice-presidents; F. P. Foster, secretary; C. E. Diehl, treasurer.

1909—Atlantic City, N. J., J. B. Yeakle, president; J. S. Craig, A. L. W. Kittridge, A. J. Bell and C. S. McCosker, vice-presidents; F. P. Foster, secretary; C. E. Diehl, treasurer.

1910—Rochester, N. Y., H. C. Bundy, president; J. S. Craig, J. W. Kelly, Jr., J. G. Kraetz and J. Berry, vice-presidents; C. R. George, secretary; C. E. Diehl, treasurer.

The headquarters of the association will be at Young's Hotel, Boardwalk and Tennessee Avenue. The rates for accommodations are: Room, without bath, one person, $1.50 per day; for two persons, $2.50; room with bath for one person, $2.00 per day; for two persons, $3.00.

An excellent programme has been arranged and a most successful convention is looked for. Arrangements are being made to provide ample space for exhibits of electrical apparatus and appliances of interest to municipal electricians.

Mr. John W. Kelly, Jr., chief of the Electrical Bureau, Camden, N. J., is in charge of the arrangements and any further information on the subject may be obtained of him.

Current Supply for Railway Selective Calling Systems.*

BY W. E. HARKNESS, OF NEW YORK.

Selective calling systems now in general use on railway telephone dispatching and message circuits may be divided into two general classes according to the method of sending out the selecting current which operates the selectors connected to the circuit. These two divisions are:

A. Combinations of current impulses.

B. A series of consecutive current impulses.

The first or combination system consists of sending over the line combinations of current impulses ranging from two to five groups, these groups being separated by predetermined time intervals. The groups of current impulses may consist of from three to ten impulses separated by intervals equal in length to the impulses themselves. The time interval between groups will then be of relatively greater length than that between the impulses forming a group.

For mechanical reasons it is necessary, in some combination call selectors, to precede or follow the calling impulses with a group of clearing-out impulses. This group contains one more impulse than the highest group in the calling combination, in order to restore all the selector mechanisms to normal.

By the combination system of calling, the maximum number of selective combinations is possible with the minimum number of current impulses. Other factors being equal, it is therefore the most economical from the standpoint of current consumption.

The second general division, employing a series of consecutive current impulses to close the signal circuit at the desired station, is limited in the total number of selections, owing to the large number of current impulses required to meet service conditions. In other words, while station No. 5 is selected with five impulses, station No. 20 will require twenty impulses, and station No. 45 a corresponding number of impulses. In service, the selectors of this type have been limited to forty-five or fifty stations, a number which may be sufficient for the present for many circuits, but which will not meet the demand for larger numbers nor permit future extensions of existing circuits.

An effort has been made with selectors using this method of operation to overcome the objection to the number and length of current impulses by decreasing the length of impulses and of the interval between them. This, however, has not been notably successful, for electrical reasons which are evident to those familiar with the telegraph. In some cases attempts are being made to adapt this type of selector to a combination method of calling.

*Abstract of paper read at the Boston Convention of the Association of Railway Telegraph Superintendents, June 24-30.

In the various types of selectors in use, two sources of current supply are employed to operate the bell or signal at the way station:

First: By providing one or more cells of battery at the way station to operate a low resistance bell, and

Second: By using current transmitted over the line wires from the same main battery which provides current for operating the selectors, to operate a high resistance bell at the desired way station.

Where the local battery bell is used, the combination call selector presents a marked advantage over the step-by-step type in total current consumption. With the combination type selector the main battery is not connected to the line during the ringing period, which is a large percentage of the total time of calling, and current is therefor not flowing from this source through all the selectors during this interval, as is the case when step-by-step selectors are used. This difference is due to the fact that with the combination type of selector, the bell contacts are held closed mechanically after being brought together by the selecting impulses, whereas in the step-by-step mechanism the bell contact is kept closed only while the selector coils are energized by the current from the main battery. If, in the mechanism of the step-by-step, this current flow were confined to the one selector at the desired station, the excess flow would not be serious, but as all the selectors on the circuit are taking current during this interval, the difference in current consumption between the two systems is considerable.

When the main line bell is employed, the two systems of selection consume practically the same amount of current for operating the bell during the ringing period. The current consumption to operate the two types of selectors may differ slightly, depending upon the type of combination selector employed.

FACTORS GOVERNING CURRENT CONSUMPTION.

The amount of current in amperes required to operate a selective system depends upon the design and construction of the selectors and the margin of operation determined upon. In practice the normal operating current of the principal selectors used ranges from eight to ten milliamperes, the latter being that customarily used in the preliminary calculations to determine the total voltage of the main battery. The current values mentioned are, however, far in excess of the minimum current at which the selectors will operate; in fact they are from two to two and a half times the minimum operating current.

In addition to the minimum operating current at which a selector will function, the maximum current at which the selector will continue to operate should be borne in mind to insure satisfactory operation of the minimum number of selectors remaining on a line which may be open near the dispatcher's office. The maximum op-

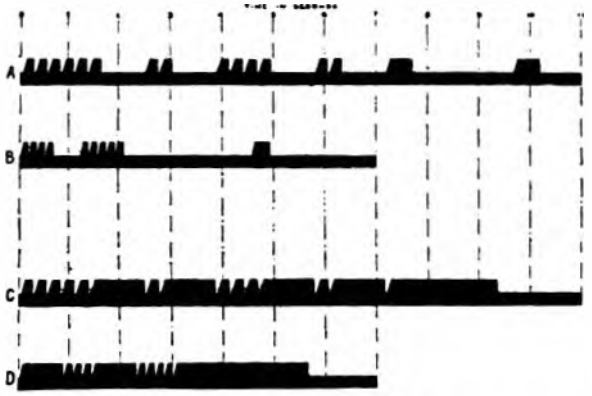
Digitized by Google

erating current should be at least three times the normal operating current.

In addition to the amount of current in milliamperes, the length of time this current is applied to the line during a call must be considered, as well as the number of calls. The length of time current is on the line depends upon the type of selector used.

The illustration shows graphically the difference in the calling keys required in four types of selectors. These are drawn to scale.

A represents that of a four-figure, eleven-seconds local bell selector key. The combination is



CALLING KEYS FOR FOUR TYPES OF SELECTORS.

2421. The six impulses in the first two seconds are clearing-out impulses. The two wide teeth at the right show the ringing interval.

B represents that of a two-figure, seven-seconds local bell selector key, the combination being 45.

C represents that of a four-figure, eleven-seconds main line bell selector key, with the combination 2421.

D represents that of a two-figure seven-seconds main line bell selector key, combination 45.

The combinations shown contain the average number of impulses per call and as shown, are the same for the local and main line bells of the two types.

When the foregoing are reduced to figures we have the following times during which the main battery is in service during one call.

	Type	Battery closed
A—Local battery bell	4 fig. 11 sec.	2.75 sec.
B—Local battery bell	2 fig. 7 sec.	1.05 sec.
C—Main line bell	4 fig. 11 sec.	7.2875 sec.
D—Main line bell	2 fig. 7 sec.	4.725 sec.

With the foregoing as a basis and various numbers of calls per day, charts have been prepared showing the total ampere-seconds required for the four types mentioned, at different rates of calling for circuits of from 10 to 50 stations. From the information thus shown, the proper ampere-hour capacity of the battery required for any circuit employing the types of selectors described may be determined.

STORAGE BATTERIES.

Storage cells are rated by their ampere-hour capacity, which is governed by the area of the plates in the cells and somewhat by the rate of discharge. The number or size of the plates used may be varied to obtain cells of different ampere-hour capacity. As selective calling systems require a comparatively low capacity and a slow rate of discharge, small cells may readily be used.

In order to provide for emergencies such as interruptions to the power circuit or trouble with the charging apparatus, it is desirable to allow an excess ampere-hour capacity. Provision for at least three days' excess ampere-hour capacity should be made; double this provision is advisable.

In assembling the storage cells into a main battery, various types of construction are employed. The form employing "couples" consisting of a negative and a positive plate with their connecting lugs burned together is the simplest and cheapest and is considered the best for this class of service.

One of the main objections urged against the storage battery has been the maintenance, an objection which seems to be due mainly to the assumption that such batteries cannot be maintained without skilled labor. This objection is believed to be less serious than has been anticipated, for the reason that the average telephone inspector or repair man can, after a little study of the instructions furnished by the manufacturers, care for a storage battery in a satisfactory manner.

CHARGING APPARATUS.

Several methods of charging the storage batteries may be employed, the choice of method to be used depending upon local conditions. They are as follows:

1—Charging direct from direct current lighting circuits, the proper amount of charging current being regulated by means of a rheostat or bank of lamps. This method may be employed only where the voltage of the storage battery is lower than that of the lighting circuit. As the usual selective circuit requires a battery of over 100 volts, this method is seldom used. This method cannot be adopted when alternating current lighting circuits are used.

2—Charging by means of a small direct current generator driven by a direct or alternating current motor operated from the commercial lighting circuits. This is the most flexible and satisfactory arrangement, as the generator may be connected directly to the line in case it is necessary for any reason to cut the battery out.

3—Charging by means of mercury arc or other forms of alternating current rectifiers. This, like scheme 1, is, to a certain extent, limited to charging batteries of a voltage lower than that of the circuit supplying current. The maximum voltage

Digitized by Google

at the battery is 115 volts when the rectifier is connected to a 220-volt alternating-current circuit, and 175 volts when connected to a 330-volt alternating-current circuit. This will, in some cases, necessitate splitting the battery into sections for charging, or providing a duplicate set of batteries to be used while the regular set is being charged.

ALTERNATING CURRENT RECTIFIERS.

The type of rectifier which is best known is the mercury arc type. There are, however, some other types which have a lower first cost, but are not capable of transmitting as large currents as the mercury arc type, nor are they as efficient. They have, however, sufficient current capacity for the service under consideration. The principal advantage of the rectifier over the motor-generator set is that it has no moving parts and the set may be operated by inexperienced employes. Its disadvantages are the renewal and breakage of the glass tube in the mercury arc type and the handling and cooling of the liquid, together with the renewal of the electrodes in the liquid types.

COSTS.

The relative costs of the several suitable types are as follows:

Basis of Annual Charge—Depreciation.

Items.	Life.	Salvage.	Depreciation.
Storage batteries	5 years	0	20%
Charging plant	8 years	25%	9.375%
Interest on investment			6%

Maintenance Charge:

Labor—It is estimated that the batteries and charging equipment will require the services of one man one day a week. The rate of pay of such a man being estimated at $3.00 per day equals, per year $156.00

Material—Acid and water for batteries per cell per year ..... .05

Oil, waste, etc., for motor generators, per set per year 3.00

Operating Expense: The power used to operate the motor-generator sets or for charging the batteries direct is based on a rate of 10 cents per kw-hour on the primary of the charging set. The efficiency of transformation is estimated at 70 per cent., which brings the cost of power at the battery terminals to approximately 14.3 cents per kw-hour.

Owing to the possibility of the storage battery receiving less attention in this service than in regular telephone exchange service, and on account of its low rate of discharge, its efficiency in selective calling service is estimated at 50 per cent. of its normal rating. On this basis, the current delivered to the line will cost approximately 28.6 cents per kw-hour, exclusive of the fixed charges.

FIRST COST OF CHARGING EQUIPMENT.

(1) Power panel for charging direct from power circuit. Panel containing low voltage cut-out rheostat, switch and fuses.

Estimated cost	$12.00
Annual charge: Rate.	
Depreciation 9.375%	$1.125
Interest 6%	.72
Total	$1.845

(2) Motor-Generator Sets.

	500 to 600 watts.	250 to 300 watts.
Type of motor, 220 volt direct current	$155.00	$120.00
Single phase alternating current	165.00	135.00
Two phase alternating current	130.00	115.00

(3) Power panels, consisting of slate panel containing switches, fuses, rheostat, starting box and ammeter and voltmeter, $95.00.

ANNUAL CHARGES.

A typical equipment will be considered. The circuit is 150 miles long, constructed with No. 9 B. & S. gauge hard drawn copper. There are thirty four-figure local battery bell selectors used, and the dispatcher is located at the end of the circuit. The number of calls per day is 300.

The main battery in this case will have a voltage of 280. The number of storage cells will be 280 ÷ 2, or 140.

First cost of 140 cells at $.50 each	$ 70.00
Annual Charges:	
Depreciation at 20%	14.00
Interest at 6%	4.20
Maintenance 52 days' work at $3.00 per day	156.00
Acid and water per year at $.05 per cell	7.00
Total annual charges	$181.20

CHARGING CURRENT.

On the basis of charging four hours per week at a 1-ampere rate we have 208 ampere-hours per year, or 58.24 kw-hours which at 28.6 cents per kw-hour equals $16.65.

The charging equipment in this case could be of 200-watt capacity, when the annual charge for this part of the plant would average $36.

The total annual expense would therefore stand as follows:

Charging equipment	$ 36.00
Batteries	181.20
Current	16.65
Total per year for storage battery equipment	$233.86

By using the charging panel and charging direct from the power circuit, this amount could be reduced to about $190.

In comparison with this we have dry cells which would cost as follows:

A 280-volt battery consisting of 215 cells, at 15.5 cents per cell, or $43.40

It is estimated that these cells will have a capacity of 15 amp. hours or 54,000 amp. seconds. At this capacity they would last approximately eight months on this circuit before they would

Digitized by Google

have to be renewed. The inspecting and testing of these cells during their life would require approximately one day a month, or a total of twelve days per year at $3.00 per day, or $36. It would also require at least two days to prepare and set up the new cells every eight months, which at the same rate of pay is equivalent to $4 per year.

The total annual expense for the dry battery installation would then be as follows:

215 cells of dry battery every eight months at 15.5 cents	$57.87
Labor, maintaining	36.00
Labor, renewing	4.00
Total, per year for dry battery equipment	$97.87

On the foregoing basis the dry cells would be the more economical, as at least four renewals of the dry batteries could be made per year before the expense would be equal to the annual expense of operating a storage battery equipment.

The preceding figures will be materially changed if we consider the same circuit using four-figure main line bell selectors. The total ampere-seconds required per day will be found in this case to be 671.4 in place of 247.5, as in the corresponding local battery bell equipment. On this basis dry cells of the capacity previously mentioned, i. e., 54,000 ampere-seconds, would last about ninety days, or four renewals per year would be required. The total annual expense for dry cells in this case would be $225.60.

The storage battery equipment would be identical, the only difference in expense being that of current, which would probably be increased. Assuming this item to be doubled the total annual expense for storage batteries would be $246.30.

If, as before assumed, the charging panel is used in place of the motor-generator set, this amount will be reduced to approximately $212.

On this basis it is believed that, although the annual expense for storage battery and motor-generator equipment is slightly above that of the dry cells, the figures are close enough to warrant the use of the storage cells, on account of the more reliable service furnished and the reserve capacity possessed by the storage cells.

Large Wireless Station at Charlestown.—The new wireless station at the Charlestown, Mass., Navy Yard will be among the most powerful in the world, having a maximum range of about 3,200 miles. There will be two aerial poles, each 170 feet high. The old equipment, mostly Stone wireless apparatus, will be supplanted by modern Telefunken sending apparatus, with a Pickard receiver. There will be a 5-kw. Telefunken high-frequency, quench-gap machine, the old sending equipment being a 2-kw. Stone low-tone spark machine. Those in charge of the station will be Mr. J. E. Simpson, chief operator, and Messrs. W. J. Stedman, F. C. Johnson, J. Lucas and J. J. Harrigan operators.

Cardinal Gibbons on Financial Combinations.

In a recent interview Cardinal Gibbons, of Baltimore, expressed his views concerning the combinations of capital for business purposes.

"An important condition in the industrial development of this country," he said, "is the fact that the right of the people to fair and honest treatment by the big business interests is daily becoming more widely recognized by broad-minded and progressive men.

"Laws are being passed and enforced for the proper regulation and control of great corporations, particularly public service companies, and the rights of the people are each year being better guarded and protected. This is as it should be; it creates honesty in business relations, and without honesty there can be no real progress.

"It was said recently by Mr. Theo. N. Vail, the head of the great telephone and telegraph interests, that the public should be considered as virtual partners in all matters that pertain to the common welfare. Therefore, he says, he believes that there should be proper public control and regulation of public service companies. This utterance from a man representing 70,000 stockholders is indicative of the progressive spirit of the times; it shows a broad appreciation of the rights of the people.

"The public has a right to exercise intelligent control over corporations which serve it with necessities. No friend of his race can contemplate without painful emotions heartless monopolies exhibiting a grasping avarice which has dried up every sentiment of sympathy in the public and created a sordid selfishness which is deaf to cries of justice and fair treatment.

"Public control and regulation will prevent such conditions. The healthy combination of human forces in the economic world can accomplish results which could not be effected by any individual efforts. Our industrial progress is so vast that great combinations of capital are now necessary forces in our business life. Many of these corporations have treated the public unfairly, many have been unjustly criticized by the public. There would be greater harmony, more benefits and less ground for complaint if everybody would keep in view the golden maxim of the Gospel, 'Whatsoever you would that men should do unto you, do ye also to them.'

"The people deserve fair and honest treatment and in return they should treat the big business interests justly. Public control and regulation should be such as to assure the people good service at fair prices, and should also protect the investor; it should prevent destructive industrial warfare, for the people in the end pay for such strife; it should end improper political interferance with the rights of the people and with the enforcement of just decisions; it should encourage honest effort to serve the people with the utilities which they require and at the same time furnish proper protection to the men who invest their money in the effort to do so."

Telephone Cable Transmission.*

BY JOHN B. ADAMS, NEW YORK.

It is my purpose in presenting this paper, to place before telephone men reliable and practical information relating to cable transmission, specifications and manufacture, which, it is hoped, will prove of value to them in solving transmission problems. There has been issued pamphlets and catalogue literature, purporting to treat the question of transmission of telephone currents in cable, along practical lines, but these, unfortunately, contain fundamental statements, which, to any one conversant with the present day principles of the art, are known to be erroneous, and the formula expressing the loss in transmission so misstated as to lead to entirely erroneous conclusions and results.

TRANSMISSION.

The factors which determine the transmission efficiency or talking value of any circuit, are resistance, capacity, inductance and insulation. As applied to a telephone circuit made up of two copper conductors of equal size, insulated with dry paper, twisted together and enclosed in a lead sheath, as a pair of conductors in ordinary telephone cable, it has been found as a result of actual transmission tests and measurements, that the inductance and leakage are so small compared with the resistance and capacity, as to be entirely negligible in their effect on the transmission.

The loss of volume in transmission, or attenuation of the current, as it is called, in a telephone cable circuit, is, therefore, dependent only upon the resistance and capacity, and the loss may be stated as being proportional to the square root of the product obtained by multiplying the resistance of the loop in ohms, by the mutual capacity in farads; i. e. Loss $= K\sqrt{R \times C}$, in which R is the loop resistance, C the mutual capacity and K a constant assumed as equalling the average frequency of the voice currents.

As an example; in the calculation of transmission losses in cable, suppose it is required to find which of the following cables will give the least transmission loss per mile, and also the length of each cable which will give the same loss or the same volume of transmission:

	Cable No. 1	Cable No. 2
Conductors, gauge B. & S....	19	22
Resistance ohms per mile loop	86	172
Mutual electrostatic capacity..	.075	.075

Applying the formula for transmission loss as above stated:

Loss in cable No. 1 $= K\sqrt{86 \times .075} = 2.54\ K.$

Loss in cable No. 2 $= K\sqrt{172 \times .075} = 3.59\ K.$

Therefore, the loss in cable No. 2—22 gauge, is $\frac{3.59}{2.54}$ or 1.41 times as great in cable No. 1—19 gauge, or, with the same capacity, 1.4 miles of No. 19 gauge cable will give the same volume of transmission, i. e. the same talking efficiency, as one mile of No. 22 gauge cable. This result has been confirmed by a large number of transmission tests. With the formula for loss in telephone cable, incorrectly stated as being proportional to the simple product of resistance and capacity (the old "K R Law"), the loss in the No. 22 gauge cable would be twice that for the No. 19 gauge cable, a result which has been proven to be entirely incorrect by actual test.

TRANSMISSION STANDARD

In calculating values of telephone transmission, it will be found convenient to adopt some standard for transmission loss, i. e., some unit of loss in terms of which the losses in any circuit can be expressed. In the absence of any accepted name for such a unit, a standard of this description which has been quite generally adopted by telephone engineers in this country, is a cable having a resistance of 88 ohms per loop mile (44 ohms per conductor mile), and a mutual electrostatic capacity of .06 microfarads per mile, with no inductance and no leakage. This is known as a standard cable and losses expressed in terms of this unit are referred to as losses in miles of standard No. 19 gauge cable, or simply miles of standard cable.

As an example of the use of this standard, in calculating losses, suppose it is required to find the relative talking efficiency of the following circuits:

Gauge	Loop Resistance Per Mile	Mutual Capacity Per Mile
13.....	21.5.....	.07
16.....	42.5.....	.07
19.....	85.0.....	.075

13 gauge $\sqrt{\frac{21.5 \times .07}{88 \times .06}} = .534$ miles standard cable.

16 gauge $\sqrt{\frac{42.5 \times .07}{88 \times .06}} = .75$ miles standard cable.

19 gauge $\sqrt{\frac{85 \times .075}{88 \times .06}} = 1.1$ miles standard cable.

That is, the losses in one mile of the above cables are equivalent to the losses in .534, .75 and 1.1 miles of standard cable.

STANDARD GRADE OF TRANSMISSION.

By a standard grade of transmission is meant the standard of transmission loss, including the loss in switchboard and substation apparatus as well as that in the portion of the circuit between apparatus terminals, commonly called the line, which is considered allowable for any particular class of service. This question of a standard transmission is of increasing importance as toll or long distance lines are extended, and is of the utmost importance that it be carefully considered in the development of new plants or in planning extensions to existing ones.

While economical consideration usually governs this question it should be borne in mind that standards of transmission have been gradually

* Abstract of paper read at Boston Convention of Association of Railway Telegraph Superintendents, June 23-30.

Digitized by Google

raised by the leading telephone companies throughout the country in meeting the increasing demands for long distance telephone service, who in so doing have found the additional investment necessary a profitable one from the standpoint of service efficiency. A few years ago a circuit having a loss of 40 miles of standard cable was considered a satisfactory one; today, however, a loss of over 30 miles is not considered satisfactory commercially. In general it may be said that a conversation over a telephone circuit under very favorable conditions cannot be carried on where the transmission loss is greater than the equivalent to 45 miles of standard cable.

STANDARD GAUGES OF CABLES.

The question of the proper gauge of wire in a cable for any particular class of service, or the gauge of cables in general to be used in the telephone plant, is dependent upon local conditions: These conditions are: 1. Grade of transmission considered satisfactory. 2. The ratio of the number of trunks to the number of subscribers' circuits entering a central office. 3. The average length of subscribers' and trunk circuits. 4. The ratio of local to toll business originating in the district or districts under consideration.

The standard wire gauges in use in cable at the present time are, 13, 14, 16, 19, 20 and 22 B. & S., and it is believed that this range of sizes will satisfactorily and economically meet any ordinary requirements which may arise. Sizes outside of this range can, of course, be used, but No. 22 is about as small as is desirable for mechanical reasons, and while conductors larger than No. 13 B. & S. have been used in this country and abroad, with further increase in the transmission efficiency, it is doubtful if the expense of such cable is justifiable except in special cases. In general the classes of service for which the different gauges are used are as follows:

Subscribers' loops.....Nos. 22, 20, 19, B. & S.
Local Trunks.....No. 19. "
Toll Board Trunks....Nos. 16, 14, 13, "
Toll lines in cables....Nos. 16, 14, 13, 12 and 10.

It is often found economical to use a combination of these conductors in the same cable, as, for instance, 50 pairs of No. 16 gauge with 50 pairs of No. 19 gauge; this is known as composite or combination cable. A cable of this class can be used economically where subscribers and high efficiency trunks are required along the same route, the economy being effected in the saving of lead in the cable sheath.

INSULATION.

Dry air is the ideal dielectric between conductors for telephone transmission, but, inasmuch as the conductors in cable could not be kept permanently separated with an all air dielectric, a separator of one or more paper ribbons is applied spirally to each conductor in such a manner as to include as much air around the conductor as possible, and to separate the wires of a pair as much as possible. The spiral application of the ribbon of paper has been found much superior to laying it around the conductor longitudinally, as it secures a greater amount of air space and a more perfect mechanical separation. Pure Manila rope paper of a suitable thickness, overlapped in applying sufficiently so that each conductor will remain completely covered under extreme conditions of bending, has been found superior to any other material, both electrically and mechanically.

The two wires of a pair with different colored insulation for identification are twisted together, the requisite number of pairs cabled or stranded up concentrically in layers, in reverse directions, and the whole wrapped with heavy paper for keeping the core in shape and for additional protection against the grounding of the conductors in the outer layer, to the sheath. The core is then dried or desiccated either in vacuum or drying ovens at a temperature sufficient to vaporize all hygroscopic moisture in the paper, and when perfectly dry the core is immediately covered with a lead pipe, the ends of which are hermetically sealed.

Cable may be made with single, double or triple wrap paper insulation, according to specifications, the triple wrap being principally used in heavy gauge cables. The choice between single wrap and double wrap paper insulation for the ordinary cable in 19, 20 and 22 gauge is a matter of individual preference. There is probably many times as much cable with single wrap insulation in use in this country as with double wrap, and it will continue to be used exclusively by its adherents for ordinary underground and aerial work. On the other hand, the alleged greater immunity from trouble, by the use of double reverse wrap insulation, especially in the work of splicing up the cable, is thought by many to be worth all of the slight extra cost over that of single wrap. It might be well to state here that this extra cost is in the lead required for a slightly greater diameter of cable. As the insulation resistance is substantially the same in either case, single or double wrap insulation makes no appreciable difference in the transmission efficiency of the cable.

MUTUAL VS. GROUNDED CAPACITY TEST.

There are two general methods of determining the electrostatic capacity of cable for telephone service, the difference between the two being the connecting of the wires under test.

1. GROUNDED TEST, SOMETIMES CALLED REGULAR TEST. This is the older method and consists of measuring the capacity between one wire and all other wires including its mate, grounded to the sheath.

2. MUTUAL TEST. This consists of measuring the capacity between one wire and its mate, all the other wires being grounded to sheath.

Considerable argument has arisen concerning the selection of one of the above tests as the proper one to use, and it has even been hinted that some manufacturers in meeting specifica-

Digitized by Google

tions, have used the mutual test which gives a lower capacity than the grounded, when it was understood that the grounded test should apply. The grounded test being the older method, it is always understood that it shall apply unless the mutual test is specified, and this is a general rule followed by all reputable manufacturers.

In dry core telephone cable of the usual construction, the mutual capacity will be less than the grounded capacity, and will vary between the limits of 60 to 75 per cent. of the grounded capacity, depending upon details incident to the manufacture of the cable. The hard-and-fast rule of Mutual = .66 of grounded, as stated by some cable makers, does not hold in practice and cannot be depended on for accurately converting grounded capacity into mutual capacity, or vice-versa.

As the ratio of mutual to grounded capacity is not constant, the question of which should be specified to secure a cable of the required transmission efficiency becomes important. In metallic circuit service, it is believed that, since the mutual rather than the grounded capacity is the constant of the cable directly indicative of its value as a talking current, the mutual is the proper test to apply, and this is now current practice among many of the larger telephone companies in this country and abroad. As there is a material difference between the results of the two tests applied to the same cable, it is, of course, important that the method of testing be specifically stated in specifications, in order to secure a cable of the desired quality of transmission.

The diameter of a cable for a specified capacity will vary with the expertness of the manufacturer. Improvements in the methods of applying the insulation, etc., have resulted in a smaller diameter for a given capacity, or a lower capacity for a given diameter. Therefore, references to the diameter of cable are omitted from specifications as giving no assurance of the desired capacity or transmission value, the results of actual tests only, being depended on.

LEAD SHEATH.

In dry core cable the life of the cable as affected by moisture or mechanical damage, is evidently dependent upon the integrity of its protecting lead sheath. The greatest care is therefore exercised to insure a sheath free from pin holes or other defects. The practice in regard to the thickness and composition of the sheath for telephone cable varies with different purchasers, but as a general guide for Nos. 22, 20 and 19 gauge high capacity cable, recommend minimum thicknesses as follows:

5	to	50	pairs.....	5-64" wall
60	"	100	"	3-32" "
120	"	200	"	7-64" "
200		up	.....	⅛" "

For low capacity cable an additional 1-64" thickness in each case should be used.

I recommend an alloy of lead with a small percentage of tin for all large and soft core cable, and for small cable which may be subject to vibration or swaying by the wind. In large cable especially the addition of a small percentage of the tin in the sheath is a much more economical way of securing additional strength and stiffness than to increase the wall thickness.

Electrical Instruments and Testing.

Every one connected with the telegraph and telephone service should know how to test lines and also be familiar with the instruments used in such work. It does not require much study to learn the mechanical operations of this important branch of the service, but of course a knowledge of electrical and mechanical principles involved in the design and construction of the instruments, and of the principles involved in measurements is the source of deep and never-ending pleasure to the ambitious student.

An excellent book on this subject, intended for the practical man, is "Electrical Instruments and Testing," by Norman H. Schneider, with new chapters on testing wires and cables and locating faults, written by Jesse Hargrave, division superintendent of the Postal Telegraph-Cable Company, Atlanta, Ga.

This work tells how to use the voltmeter, ohmmeter, ammeter, potentiometer, galvanometer, the Wheatstone bridge and standard portable sets. The apparatus described is modern and in universal use, and the tests are such as are required daily.

Mr. Hargrave carries the student step by step through the different methods of testing for faults, insulation and conductivity, cable faults, etc., and the simplest language possible is used. The formulas given are explained in the text preceding them, and examples are worked out in simple arithmetic.

This is one of the most practical and useful books on electrical testing instruments and testing that has been published and is fully illustrated with views and diagrams of instruments used in this line of work. Every one who desires to widen his knowledge on electrical matters should have a copy of this book in his library. Even if he never has the opportunity to make an actual test he will learn a great deal from the work that will improve his mind and general knowledge of things electric.

The price of this book is $1.00 and copies can be had of TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

Monkey Investigates Telegraph Circuits.—Mr. W. B. Kendall, manager of the Western Union Telegraph Company at Dallas, Tex., has among his records for wire interruptions a trouble ticket that, to say the least, is novel. It reads—"Closed third circuit open in Copleys Jungleland Theater. Monkey took out fuse and turned in signal five times."

Atlantic City Reunion of Old Time Telegraphers' and Historical Association and Society of the United States Military Telegraph Corps.

For the first time in their history the Old Time Telegraphers' and Historical Association and the Society of the United States Military Telegraph Corps will hold their reunion at Atlantic City, N. J. The dates selected are September 5, 6 and 7, and there is no doubt that the members and their families who attend will find in Atlantic City a delightful atmosphere for their meeting. That famous seaside resort, with its celebrated seven-mile boardwalk and its healthful air direct from the Atlantic, is full of life and enjoyment, and a more charming place for the reunion could not have been chosen.

The Atlantic City reunion is the thirtieth held by the twin organizations, and there is every indication that each member who can get away from

COL. W. B. WILSON.
President of Old Time Telegraphers' and Historical Association and Society of the United States Military Telegraph Corps.

duty will be present with his family to enjoy the delights of this city by the sea.

This reunion will mark the fiftieth anniversary of the founding of the United States Military Telegraph Corps and the event will be celebrated by appropriate ceremonies.

Following is the official programme of the meetings:

Tuesday, September 5.—10:00 a. m.: Business meeting of the Old Time Telegraphers' and Historical Association called to order at the Marlborough-Blenheim by the retiring president, Mr. W. J. Lloyd, of Chicago. Address of welcome and response. Installation of the new President, Col. W. B. Wilson of Holmesburg, Philadelphia.

Transaction of business, etc.—2:00 p. m.: Roller-chair trip. 7:30 p. m.: Business meeting of the United States Military Telegraph Corps. 8:30 p. m.: Concert and entertainment on Steel Pier.

Wednesday, September 6.—Morning: Ocean sailing. Afternoon: Trolley party to Ocean City. Evening: Concert and theatre entertainment on Million-Dollar Pier.

Thursday, September 7.—Morning: Ocean bathing. Afternoon: Go as you please. Evening: Banquet at the Hotel Shelburne.

The chairmen of the various committees are: Mr. John Wintrup, reception committee Old Time Telegraphers' and Historical Association; Mrs. Frank E. Maize, ladies' reception committee; Mr. G. W. Deetz, Atlantic City, N. J., committee on hotels; Mr. John W. Reed, committee on badges; Mr. C. E. Bagley, committee on banquet.

The reception committee of the United States Military Telegraph Corps is composed as follows: Messrs. Jesse W. Crouse, chairman; Richard Graham, John Wintrup, Isaiah D. Maize, of Philadelphia; Henry H. Atwater, William L. Ives, George M. Huntington, Marion H. Kerner, Frank A. Stumm, Charles W. Pearson, Alfred Winder, Thomas T. Eckert, Jr., David H. Bates, Jr., Verdie J. Knittle, Albert Eckert Chandler, of New York, and Thomas Wallace Wilson, of Atlantic City, N. J.

Mr. G. W. Deetz, manager of the Western Union Telegraph office at Atlantic City, as chairman of the hotel committee, will be pleased to assist the members in arranging for their hotel accommodations. They should give this important matter their earliest attention, however, on account of the crowded condition of the hotels at this season of the year.

It is possible that reduced railroad rates may be in effect from various sections in the country to Atlantic City during the time of the convention, and it would be well for members who intend to be present at the meeting to inquire of their local railroad agent in regard to this.

The convention headquarters will be at the Marlborough-Blenheim, which is one of the leading hotels in Atlantic City.

Mr. Theo. N. Vail, president of the American Telephone and Telegraph Company and of the Western Union Telegraph Company, and Mr. E. J. Nally, vice-president and general manager of the Postal Telegraph-Cable Company will probably be present at the reunion, as well as many other prominent telegraph and telephone officials.

At the banquet which will be held at the Hotel Shelburne, on the evening of September 7, Col. W. B. Wilson, the president of the Old Timers, and also president of the Society of the United States Military Telegraph Corps, will act as toastmaster. Among the speakers will be several prominent telegraph and telephone people.

Great interest seems to center in the fact that Mr. Edward Lynn Morse, son of Prof. S. F. B. Morse, inventor of the telegraph, will be present at the Atlantic City reunion of the Old Time Telegraphers' and Historical Association, and the

Digitized by Google

Society of the United States Military Telegraph Corps. Mr. Morse states that he anticipates much pleasure from meeting the members of the two telegraph societies at Atlantic City.

He was in the telegraph service for about six months in the winter of 1878-79, when he was a clerk in the office of the late John Van Horne, vice-president of the Western Union Telegraph Company, New York. He soon became convinced, however, that he was not cut out for a business man, and has since then devoted himself to an artistic career, having acquired his father's tastes in that line.

Mr. Morse was born at Poughkeepsie, N. Y., on March 29, 1857, and is the youngest of Prof. Morse's children by his second wife. One of his brothers, William Goodrich Morse, is living in California, and has a daughter, Miss Leila Livingston Morse, who lives in Rochester, N. Y. It will be remembered that she sang at the Carnegie telegraph dinner in New York a few years ago. Mr. Morse's sister, Mrs. Franz Rummel, lives in Washington, but spends most of her time abroad. She has three sons. Mr. E. L. Morse has two children, a son and a daughter.

All of Prof. Morse's children and grandchildren by his first wife are dead, with the exception of one son, James Edwards Finley Morse, who is now a very old man. There are, however, some great grandchildren still living.

Mr. Morse is at present engaged in the task of selecting and putting together his father's letters for publication, and states that he has yet several years' work before him. He has also written an article on his father's work as a painter which will appear shortly in "Scribner's Magazine," and will be illustrated by a number of reproductions of the paintings.

Following is a complete list of the living members of the United States Military Telegraph Corps so far as known:

The following members of the United States Military Telegraph Corps have died since the last reunion:

John D. Voltz, Elgin, Ill.; Gen. Thomas T. Eckert, Elberon, N. J.; Milton F. Adams, Wheeling, W. Va.; John W. Pitfield, St. John, N. B.; Capt. Wm. A. Sheldon, New York; A. C. Schnell, Des Moines, Iowa; M. Y. Holley, Chicago, Ill.; John L. Sponagle, Seattle, Wash.; John Harveycutter, Salem, Va.; Jos. Knittle, Brooklyn, N. Y.; Isaac McMichael, Baltimore, Md.; M. D. Crain, St. Louis, Mo.; William A. Dunn, Baltimore, Md.; Jesse H. Robinson, Washington, D. C.; George J. Lawrence, Albion, N. Y.; Thomas Langdon, Minneapolis, Minn.; Thad M. Schnell, Des Moines, Iowa; Joseph Hansen, St. Joseph, Mo.; Geo. C. Peirce, Grand Rapids, Mich.; John E. Jayne, DeWitt, Mich.; L. Ford Perdue, Terre Haute, Ind.; J. C. Duncan, Knoxville, Tenn.; Wm. D. Sargent, Brooklyn, N. Y.; Madison Buell, Buffalo, N. Y., and Phil. B. Fraser, Stockton, Cal.

The following members of the Old-Time Telegraphers' and Historical Association have died during the past year:

I. W. Hallam, W. A. Van Orden, A. B. Crane, Wm. H. Jackson, Fred Catlin, T. P. Scully, C. W. Black, Anthony F. Saunders, John A. Caldwell, K. C. Morehouse, Jas. L. Miller, F. E. Chaffey, Wm. G. Moffett, J. B. Boyer, Chas. A. Gill, A. J. Brahany, S. S. Dickenson, D. R. Downer, A. E. Sink, Geo. A. Sinclair, B. F. Dillon, W. N. Eastabrook, Jerome Hill, Wm. H. H. McCormick, L. C. Whitney, Fred N. Bassett, A. A. Offutt and C. J. Lawson.

Addresses Wanted.

We are requested by Mr. David Homer Bates, secretary of the Society of the United States Military Telegraph Corps, 658 Broadway, New York, to ask our readers who may know the addresses of any of the members named in the following list to advise him at once by postal card:

Armstrong, Ewing L.; Benedict, C. H.; Hauxhurst, H. C.; Hood, Oliver Perry; Huyck, Maynard; Lowe, James; McCleverty, Jos. D.; McMurtry, B.; Shuman, W. A.; Sisson, W. H.; Stone, Ellis; Taylor, Periander A.; Waddell, F. G.; Waddell, Orin J.; Webb, J. G. and Webster, Geo. C.

Mr. J. Elliot Smith, formerly and for many years superintendent of fire alarm telegraphs of New York, and an Old Time and Military Telegrapher, now living in retirement at Portland, Me., writes: "You are quite right in keeping me on your list of subscribers. I never fail in finding something in the AGE of interest except the passing on of some one of the 'old guard.'"

KERITE

INSULATED WIRES and CABLES

DEPENDABLE

Kerite Cables installed upward of 35 years ago, and exposed to deteriorating influences, are giving perfect service to-day.

EFFICIENT

Kerite does not rely upon the rubber in its composition for insulating efficiency. Kerite itself is a compound having superior insulating qualities.

SERVICE

A half century of successful service has demonstrated that Kerite possesses the essential qualities of safety, reliability and economy to an exceptional degree.

Kerite Insulated Wire and Cable Co.

The Railroad.

Mr. W. F. Williams, superintendent of telegraph, Seaboard Air Line, Portsmouth, Va., was a recent New York business visitor.

Mr. F. S. Spafard, assistant superintendent of telegraph Chicago, Rock Island and Pacific Railway, Chicago, is now acting superintendent of telegraph, filling the vacancy caused by the death of J. G. Jennings.

Mr. E. E. Lillie, superintendent of telegraph and of car service of the North Bank railway, Portland, Ore., has been promoted to the position of superintendent of telegraph of the Spokane and Inland Empire Railroad, with headquarters at Spokane, Wash.

Mr. Charles Selden, superintendent of telegraph of the Baltimore & Ohio Railroad Company, Baltimore, Md., has been appointed inspector of transportation of the entire system in addition to his duties as superintendent of telegraph. This promotion is a further recognition of Mr. Selden's ability as a railroad official.

J. G. Jennings, superintendent of telegraph of the Chicago, Rock Island & Pacific Railroad, Chicago, and a prominent member of the Association of Railway Telegraph Superintendents, died in Chicago, August 19. Mr. Jennings attended the recent Boston cenvention of the Association and was then in the best of spirits. His many friends will be shocked to learn of his untimely death. Mr. Jennings was born in Bellaire, Ohio, June 4, 1862. After leaving school, in 1878, he accepted a position on the Pennsylvania lines west of Pittsburgh, and remained with that company until July, 1904, when he received the appointment of superintendent of telegraph of the Rock Island lines.

M. H. Clapp, Superintendent of Telegraph, Northern Pacific Railway.

Mr. Martin H. Clapp, division plant superintendent of the Western Union Telegraph Company at Chicago, has accepted the position of superintendent of telegraph of the Northern Pacific Railway with headquarters at St. Paul, Minn., vice Mr. O. C. Greene, retired. Mr. Clapp was born at Montague, Mass., in 1874. After attending the common and high schools in Massachusetts, he was graduated from the Worcester Polytechnic Institute in 1895 with the degree of S. B., in electrical and mechanical engineering. After graduating, he worked for a year in the General Electric Company's shop at Schenectady, N. Y., and afterwards for eight years for the American Telephone and Telegraph Company in various positions, as inspector, district inspector, special agent, etc. He was with the independent telephone interests for three years in the Middle West, serving first as consulting engineer of a conference committee, composed of members from various independent telephone companies. For a short time he was chief engineer of the Kinloch Long Distance Telephone Company, at St. Louis, and later chief engineer of the Rochester Telephone Company at Rochester, N. Y.

Over four years ago Mr. Clapp returned to the Bell interests and served one year as supervisor of maintenance for the American Telephone and Telegraph Company of Chicago. For two and one-half years he was division superintendent for the same company at Chicago, and in August, 1910, was appointed division plant superintendent of the Western Union Telegraph Company in that city.

Mr. Clapp assumed his duties as superintendent of telegraph of the Northern Pacific Railway Company August 1. He is an associate member of the American Institute of Electrical Engineers.

Obituary.

E. H. Brown, aged 67, formerly manager of the Western Union office at St. Louis, Mo., died in Chicago July 20. At the time of his death he was in the employ of the Postal Telegraph-Cable Company, at Chicago.

Miss Anna M. McNerny, formerly attached to the manager's office of the Western Union Telegraph Company, Buffalo, N. Y., died in that city recently. She was a sister of Mr. J. G. McNerny of the Buffalo office.

Capt. George W. Harrison of Piedmont, W. Va., a veteran telegrapher and railroader died at that place on June 6 of congestion of the lungs. He was seventy-four years of age and a native of Wheeling, W. Va. Capt. Harrison rendered valuable service to the government all through the years of the rebellion, either in the telegraph or the railroad departments. He was also private secretary to Senator Henry G. Davis of West Virginia during that gentleman's term of office. He was well known to the telegraph fraternity and an occasional attendant at the reunions of the Old Timers. Capt. Harrison held important railroad positions for many years until about three years ago when he retired from further active duties.

Madison Buell, one of the oldest and best known telegraphers in the United States, and an electrician and inventor of note, died in Buffalo, August 20, at the age of 77 years. Seven years after the invention of the telegraph by Professor S. F. B. Morse, Mr. Buell entered the Buffalo office of the New York, Buffalo and Albany Telegraph Company as messenger, in February, 1847. In November of the same year he became an operator. On the breaking out of the Civil War, in 1861, he went to Washington to enter the Government telegraph service, at the request of General E. S. Sanford, president of the American Telegraph Company, at New York. Mr. Buell was assigned to several positions of trust during the war, and was selected by Secretary of War Stanton and Major Thomas T. Eckert, to fill the post of superintendent of telegraph of the line between Washington and General McClellan's army during the peninsular campaign. He was in charge of this line for nearly four years, and was highly complimented by his

Digitized by Google

superior officials for the able manner in which he performed the delicate duties of his position. Mr. Buell invented and introduced the universal switchboard which is now in general use. He has been located in Buffalo with the Western Union Telegraph Company for many years, and has held various positions of trust with that company.

Inter-Phone Bulletin.—"The Selection, Installation and Wiring of Inter-Phone Systems" is the title of Bulletin No. 1105, just issued by the Western Electric Company. It is a very complete and comprehensive bulletin on the subject of interior telephone systems and is illustrated with sixty-six cuts and diagrams. Twelve different systems are described including sets used for two to six-party common ringing and common talking service, and sets for twenty-four station installations where selective ringing and selective talking are desired. The bulletin tells how to choose the best system for every conceivable service, and gives valuable information on the installation of the sets.

Western Electric's July Business.—The gross sales of the Western Electric Company for July show a falling off of three per cent. as compared with the same month last year, but the seven months of the current fiscal year which have elapsed are four per cent. ahead of the corresponding period of last year. The showing to date, which is at the rate of $66,000,000 for the year, is close behind the company's high record of $69,000,000 for 1906.

Telephone Train Dispatching on Toledo and Ohio Central.—The Toledo and Ohio Central Railroad has ordered forty-eight Western Electric telephone selector equipments for use on its Eastern Division. There will be two circuits equipped, one extending from Bucyrus to Toledo, a distance of seventy miles, and the other from Bucyrus to Thurston, a distance of seventy-eight miles.

Telephone Train Dispatching.—The Chicago & Northwestern Railroad, which has had Gill selectors in use for some time between Chicago and Fond du lac, Wis., has placed an order for thirty-eight Gill selector local battery Bell telephone train dispatching outfits, together with two 40-key cabinets for Gill calling keys.

New Supply House for Richmond.—The Western Electric Company will soon open a supply house in Richmond, Va. It will be in charge of Mr. H. W. Hall, formerly manager of the Denver house.

Removal of Headquarters.—The Smith Premier Typewriter Company has recently removed its executive offices from Syracuse, N. Y., to 319 Broadway, New York.

Prizes for New Subscriptions To Telegraph and Telephone Age.

TELEGRAPH AND TELEPHONE AGE offers prizes to the amount of $100 in cash to those of its regularly appointed agents who send in the greatest number of new subscriptions and renewals during the months of September, October and November, and up to December 21. The prizes will be distributed as follows: First, $50; second, $25; third, $15, and fourth and fifth, $5 each.

Following is a copy of the notice sent to all agents of this publication:

"As a special incentive to our agents to put forth their best efforts to get us new subscribers, we are offering $100 in cash prizes to those who send us the greatest number of new subscriptions and renewals during the months of September, October and November, and up to December 21, which will be the closing date of the contest. These prizes will be distributed as follows: First, $50; second, $25; third, $15, and the fourth and fifth, $5 each.

"This will be an excellent chance for agents to earn a substantial amount of money not only by capturing a prize, but also from the usual commissions earned from the subscriptions sent in.

"We have endeavored to make the prizes large enough to be attractive and think we have made it well worth your while to put forth your best efforts to secure one of them.

"This contest is limited to new subscriptions and renewals only and does not include book orders, on which we make very little if any profit.

"The contest is urged in the interests of our circulation, which we think ought to be very largely increased during the four months, and we are certain that with a little effort on your part you can assist us very materially to increase our field of usefulness along educational lines. Money must accompany all orders for subscriptions and you will be posted in each issue of the paper or by circular as to the progress of the contest. Many of our agents secure subscriptions or renewals for from two to ten years. In cases like this a five or ten years' subscription will count as five or ten yearly subscribers, as the case may be. In fact, the total amount of money received for subscriptions will decide the contest." In the event of a tie on any of the prizes, which is unlikely, the prize will be divided equally between those entitled to share in it.

Those at points where we have no agents will find it to their advantage to secure an agency appointment to canvass their section and participate in this contest.

Many subscribers can be secured in this way, and the active canvasser in a small town will find as great an opportunity to win a prize as will a regular agent in a large city. It must be remembered that all operators are not in the cities. Many permanent agencies can thus be established to the present and future advantage of those participating in the contest.

Write to J. B. Taltavall, TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York, for fuller particulars.

Wireless Ship Operators.

Since the Wireless Ship Act went into effect on July 1, one hundred and forty-eight candidates for wireless ship operator's certificates have been examined at the Brooklyn Navy Yard up to August 16. Out of that number ten have failed to qualify. The examination is compulsory for all wireless ship operators. The questions are practical and must be answered partly in writing and partly verbally, but all bear distinctly on the wireless apparatus.

The principal cause of the failure of these applicants to pass the examination was their ignorance of wireless apparatus. They knew nothing about the instruments. In most cases they were only operators and could not make any repairs or alterations in case of a breakdown or a readjustment.

The main object is to get men who are familiar with the apparatus in their charge and who know how to make adjustments and repairs in time of emergency. The certificates are granted and marked "excellent," "very good," "good." Any operator may apply for examination who has in his possession a letter from a steamship or wireless telegraph company stating that the applicant is or expects to be employed by such company.

Each wireless operator is supplied with a copy of a general letter of instructions regarding the examination of wireless ship operators sent to the collector of customs at New York by the Secretary of the Department of Commerce and Labor at Washington. After directing attention to Section 1 of the Wireless Ship Act of June 24, 1910 (see page 347 of our issue for May 16), the instructions read as follows:

"(1) On March 29, 1911, you were advised that wireless operators, holding valid certificates, issued by any government which is a party to the Berlin Radiotelegraphic Convention, will be recognized as persons 'skilled in the use of such apparatus,' unless in the case of a specific individual there may be good reason to doubt the operator's skill and reliability. Such certificate should be ready at hand for the inspection of customs or other officers before the ship departs from the United States.

"(2) Pursuant to the power bestowed upon the Secretary of Commerce and Labor by Section 4 of the Wireless Ship Act of June 24, 1910, the following regulations are promulgated for other wireless ship operators.

"(a) The Department of Commerce and Labor will issue operators' certificates of skill in radiocommunication, and operators holding them will be recognized as persons 'skilled in the use of such apparatus' within the meaning of the Act cited, unless in the case of a specific individual there may be good reason to doubt the operator's skill and reliability. Such certificates should be ready at hand for the inspection of customs or other officers before the ship departs from the United States. It is recommended that they be kept in the wireless operating room.

"(b) To secure a certificate an operator will pass an examination in the adjustment of apparatus, correction of faults, change from one wave length to another, transmission and sound reading at a speed of not less than fifteen words a minute, American Morse, twelve words, Continental.

"(c) The examinations will be held at the United States Navy Yards at Boston, Mass., Brooklyn, N. Y., Philadelphia, Pa., Washington, D. C., Norfolk, Va., Charleston, S. C., New Orleans, La., Mare Island (San Francisco), Cal., and Puget Sound, Wash., and also at the Bureau of Standards, Washington, D. C. On the Atlantic and Gulf coasts the examinations will begin on or about May 15; on the Pacific coast, on or about May 18. Applicants for certificates should communicate in writing with the Commandants of the Navy Yards named, or to the Director of the Bureau of Standards to ascertain the day and hour when they can be examined. The certificates will be at the places named.

"(d) After an applicant has secured a certificate he should go before a notary public to take the usual oath for the preservation of secrecy of messages received in the line of duty.

"(e) The certificate will be valid for two years, subject to suspension or revocation by the Secretary of Commerce and Labor for cause."

Chief Gunner W. H. F. Schluter, U. S. N., assistant to the officer in charge of the electrical class at the Brooklyn Navy Yard is conducting the examinations at that point.

Large Reproduction of a Cablegram.—On page 564 of our issue for August 16 we presented a picture of a large reproduction of a cablegram of congratulation from Mr. Adolphus Busch to the delegates at the recent convention of the American Medical Association who visited his beautiful gardens in Pasadena, Cal. The group in the foreground included Mr. Moody Rosenquist, manager of the Postal office at Pasadena, Cal., besides those mentioned in the article accompanying the picture. Mr. Rosenquist's friends will no doubt readily recognize his features as the picture is a particularly clear one.

Heliographic Signaling.—Heliographic signals were exchanged recently between Mr. Charles J. Glidden, a well-known former telegrapher and telephone official on Appledore Island, Isles of Shoals, Mass., eight miles at sea, and Mr. S. A. Booth, at New Castle, N. H. The Morse telegraph code was used.

Telegraphs and the Hot Weather.—The extremely hot weather experienced this summer, accompanied by severe thunderstorms, considerably affected the telegraph systems on the Continent of Europe, and caused long delays and congestion of business on the wires.

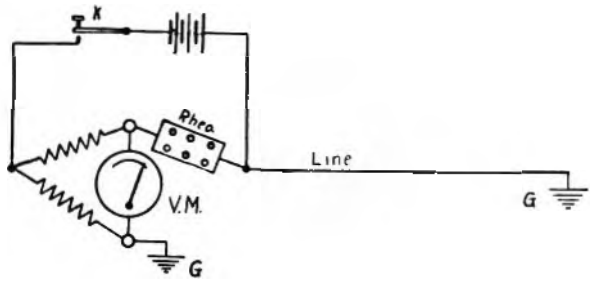
Measuring the Resistance of Grounds.

BY D. B. GRANDY, ST. LOUIS, MO.

It is often desirable to ascertain the condition of ground connections. A defective ground will interfere with the proper working of a quadruplex, prevent lightning arresters from performing their protective functions, and may become a source of danger to telephone and telegraph apparatus, and even to the safety of those in charge.

Before the advent of the generator, it was possible to obtain fairly accurate measurements of the resistance of grounds by direct measurements with the bridge, but this method is not now feasible. One of the methods in use by the American Telephone and Telegraph Company which gives very satisfactory results, is given as follows:

The line and ground connections are directly the reverse of those used for the "Varley" measurement. Either a Thompson, or tangent galvanometer or a voltmeter, should be used, as the ordinary galvanometer does not show the de-



MEASURING THE RESISTANCE OF GROUNDS.

grees of deflection. The procedure is as follows: Ascertain the resistance of the wire to be used, then connect it to the distant ground which it is desired to measure. Plug out all resistance in the rheostat, and note the deflection caused by the "ground current," with key open. This will usually vary considerably, but the mean average deflection should be taken. Call this zero. Then close the key, with positive pole of battery to line, unplug resistance until the same mean deflection is obtained, which call X. Reverse the battery, again close the key and change the resistance until the same mean deflection is again shown, which call Y. Then, $2\frac{XY}{X+Y}$ = resistance of the home and distant grounds, plus that of the wire. Deducting the resistance of the wire, the remainder is the resistance of the home and distant grounds. If the home ground was properly installed, its resistance should be practically nothing, and the figures obtained would be the resistance of the distant ground alone.

Study of the Quadruplex.

The duplex and quadruplex of today are, in principle, the same as they were in the beginning, the differences being largely due to refinement of details. An excellent book on the quadruplex is that of Maver and Davis', "The Quadruplex," which was published many years ago but which is still a valuable work on the subject. The chief feature of the book is its easy method of describing the principles underlying the duplex and the quadruplex, and after these have been mastered the minor differences in the present day instruments can be readily understood.

In our department headed "Questions to be Answered" we are now using "The Quadruplex" as a basis for questions, in the same manner as was done with Jones' book of diagrams.

Besides the duplex and quadruplex the Wheatstone system of telegraphy is fully described and illustrated, and a chapter on repeaters gives a very clear explanation of the principal repeaters in use in this country.

From the chapter headings an idea of the scope of the work may be obtained. Chap. 1. Development of the Quadruplex; 2. Introduction and Explanatory; 3. The Transmitter, Rheostat and Condenser; 4. Stearns Duplex; 5. Instruments of the Polar Duplex; 6. The Polar Duplex; 7. The Quadruplex; 8. The Dynamo-Electric Machine in Relation to the Quadruplex; 9. The Practical Working of the Quadruplex. The two last chapters are on Telegraph Repeaters and the Wheatstone Automatic Telegraph. Copies of this book may be obtained at $1.50 each by addressing Telegraph and Telephone Age, 253 Broadway, New York.

Boston Postal Outing.

On the invitation of president Clarence H. Mackay, extended through superintendent C. A. Richardson, about forty Boston officials, branch managers and clerks and out-of-town managers enjoyed an outing at Nantasket Beach on Saturday, August 12. Meeting at the offices of superintendent Richardson at 1 o'clock, acquaintances were renewed, and Mr. F. B. Travis, the newly appointed manager, was introduced. Mr. Travis, however, is no stranger to the employes of the Postal company in Boston as he was chief operator of that office for ten years prior to 1908 when he was appointed manager at Washington, D. C. Mr. Travis has been in the service of the company for twenty-one years and the outing was delayed for some time that he might be present. Co-operation and the promotion of good fellowship was the keynote of informal talks by Messrs. Richardson and Travis. After a most pleasant sail down the harbor the party spent a few hours bathing and visiting the different attractions, followed by a banquet at the Paragon Park palm garden, returning to Boston by a late boat. Those who took the trip were: C. A. Richardson, superintendent; F. B. Travis, manager; J. D. McDonald, chief operator; L. W. Hoyt, wire chief; J. J. Coen and P. J. Farrell, assistant wire chiefs; D. Carter, traffic chief; C. W. Lanfair, night chief operator; F. J. McGinnis, assistant cashier; F. Ferry, J. J. Driscoll, D. F. Kinnealy, W. A.

Digitized by Google

Reicherter, clerks; G. W. Downey, J. A. Coughlan, J. J. McCarthy, R. E. Tobin, F. M. Simms, J. J. Kennedy, P. M. Batchelder, P. S. Durgin, J. A. Finn, J. R. Sullivan and R. C Smith, branch managers, all of Boston; and the following out-of-town managers: W. H. Reagan, Fall River, Mass.; N. S. McDonald, New Bedford, Mass.; T. B. Walsh, Fitchburg, Mass.; I. W. Colbath, Haverhill, Mass.; P. J. Macken, Springfield, Mass.; G. S. Bowser, Lynn, Mass.; F. N. Cooke, Worcester, Mass.; C. C. Ramsay, Portland, Me.; H. C. Knowles, Pawtucket, R. I.; L. A. Boone, Newport, R. I.; F. J. Dickey, Manchester, N. H.

Postal Conference in Pittsburgh.—District superintendent Henry Scrivens, Pittsburgh, Pa., entertained fifteen managers of his principal offices on August 15, in that city. The party spent the morning in sightseeing and had luncheon at one of the principal hotels. They afterwards attended the National League baseball game. This was followed by a conference of several hours, winding up the day with a dinner at the Fort Pitt Hotel. During the dinner several interesting addresses were made and a group photograph taken. The affair was greatly enjoyed by those who participated.

LETTERS FROM OUR AGENTS.

NEW YORK, WESTERN UNION.

Edwin Butler, aged 57, an old employe of the machine shop, 195 Broadway, died at New York August 11.

Mr. Jacob F. W. Ulrich of this office has sailed for Brazil, where he has accepted a position with the Amazon Wireless Telegraph and Telephone Company. He is a native of New York where he was born September 21, 1859, and his entire business career has been spent in and near this city. He has been an attaché of this office for the past thirty years.

NEW YORK POSTAL.

E. W. Applegate, aged 62, an operator in this office, died at his home in Hoboken, N. J., on August 24. Mr. Applegate had held many important positions in the telegraph service and had been at different times identified with machinery interests. He was also an inventor of many electrical devices, and a first class operator and electrician. He was identified with the Western Union service beginning at Toledo, Ohio, in 1875, and was at one time chief operator of the New York main office of this company when it was located at 187 Broadway.

The great telegraphic song hit, "SEND ME A NIGHT LETTER, DEARIE." Good, catchy music; beautiful title design magnificently printed in colors. Title contains night letter. Sung all over New York, 17c. by mail. All popular music sent by mail.

B. L. BRANNAN,
195 B'way, N. Y.

AMARILLO, TEX., WESTERN UNION.

An overland repeating station has been established at this point and the office equipped with a modern plant. Mr. H. W. Cantrill, for several years repeater chief in the overland division at Albuquerque for the Postal Telegraph-Cable Company, has been appointed manager. Mr. H. L. Converse, former repeater chief at Des Moines, Iowa, with the Postal company, has been appointed chief operator, and A. W. Daniels and J. H. Crane second and third trick chiefs, respectively.

T. M. B. A. Assessment.—Assessment No. 528 has been levied by the Telegraphers' Mutual Benefit Association to meet the claims arising from the deaths of William J. Lee at Washington, D. C.; John E. Grace at Lundy's Lane, Va.; Charles M. Campbell at Williston, N. D.; David Bailey at Boston, Mass.; Joseph Hanson at Hot Springs, Ark.; Harmon M. Sage at Evanston, Ill.; Jacob Klein at Rochester, N. Y.; Winfield S. Cole at Avon, N. Y.; Barney Murtha at Cincinnati, Ohio; James Goodall at Sayre, Pa.; Charles H. Lord at Seattle, Wash., and John S. Dunnavent at Clinton, Ky.

A certificate of membership in the Telegrapher's Mutual Benefit Association, 195 Broadway, New York, affording protection for the family and dependents in the amounts of $500 or $1,000, which is at once available and cannot be diverted from its mission, should be held by every eligible person between the ages of 18 and 45 engaged in telegraph and telephone service, either commercial or railroad. If those not now members could realize and fully understand the stern necessity for beneficial help too often experienced by bereft families, would they not make earnest effort to secure such provision? Write for particulars.

TRANSMITTING MACHINES

I am placing on the market improved YETMAN TRANSMITTING TYPEWRITERS, and KEYBOARD TRANSMITTERS without typewriting features. Am prepared to exchange, repair or rebuild all old machines. Write for catalogues and particulars to

James Uncles, NORTH ADAMS Massachusetts

Rubber Telegraph Key Knobs.

No operator who has had to use a hard key knob continuously should fail to possess one of these flexible rubber key caps, which fits snugly over the hard rubber key knob, forming an air cushion. They render the touch smooth and the manipulation of the key much easier. Price, fifteen cents.

J. B. Taltavall, TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

Every one engaged in telegraphy and telephony should be a constant reader of TELEGRAPH AND TELEPHONE AGE. It gives the latest news in both these fields. Subscribe now. Subscription price, $2.00 per year.

SOME POINTS ON ELECTRICITY.

BY WILLIS H. JONES.

Special Features of the Athearn Quadruplex.

(Concluded.)

The new standard quadruplex installed by the Western Union Telegraph Company since the combination with the American Telephone and Telegraph Company differs from the old apparatus principally in the manner employed to steady the current and accelerate the building up of the signals. Heretofore the outgoing current has been greatly retarded not only in reaching the external conductor by first having to traverse an unnecessary amount of inductive resistance in the home set, but also in being choked back and banked up, so to speak, when it encountered similar conditions in the distant apparatus. This caused an unevenness in the current in the line which tended to retard the formation of signals, besides becoming a source of induction to be felt on adjacent circuits.

In addition, the former arrangement permitted the static, or return charge of the wire to exert its full power except as far as its effect could be diminished by neutralization. In the new quadruplex this charge, or at least as much of it as is not neutralized, is utilized to good advantage by forcing it through the coils of a holding magnet in close proximity to the lever of the neutral relay.

Again, although choke or impedance coils are added to the circuit the normal current does not choke up on the line as in the old system, but divides between an inductance and a useful channel at the end of its journey, where it acts quickly. Furthermore, as the polarized relay is placed in a bridge the resistance of its coils to the outgoing current is practically eliminated. Hence the home current reaches the external circuit sooner in the new than in the old method.

These claims are of course somewhat general in character and by some persons may be considered a mere assertion, but the fact that Mr. Athearn's quadruplex actually works on all four corners on the same circuits that were thus unworkable with the old apparatus, proves conclusively that such claims are well founded.

If the reader will study closely the operation of each new accessory with which this multiplex system is equipped he will not only perceive that the beneficial results expected should naturally follow, but will also derive much interesting information in the explanations given as to the causes of such results.

For instance, note the manner in which the static is utilized to energize the holding coil on the neutral relay, which is in series with a condenser.

Mr. Wm. Finn, in his description of the quadruplex published in this journal November, 1910, expressed the action clearly in these words:

"At the moment battery contact is broken at the distant polechanger the magnetism previously excited in the receiving apparatus suddenly collapses, and in doing so generates an 'extra current' that is utilized by affording for it a path through the holding coil, the direction of the current being made to correspond with the discharge from the holding condenser whose plates had been previously charged by the distant battery current."

This extra current, it may be added, is further amplified by the presence of the impedance coils which form part of the multiplex equipment. The combination of all these hitherto undesirable effects, now acting in concert and in the proper direction, causes the holding magnet to retain the lever of the neutral relay firmly on its contact points until the period of break is over.

The impedance coil is also valuable in other ways. The magnetic variations in the core of impedance coils caused by the operation of the distant polechanger create momentary extra currents, part of which find their way through the bridged polar relay, and as their direction is invariably the same as that of the incoming or marking current, they strengthen the polar side also. The impedance coils in combination with the spark condenser also tend to dampen the usually sharp or abrupt breaking of the current when signals are made, hence the induction felt in adjacent circuits when this quadruplex is working is diminished.

Some day when all multiplex circuits are equipped

Digitized by Google

with this apparatus, or something similar, the induction problem will have been nearly solved and the harmful effect now experienced in adjacent telephone circuits greatly diminished.

The lesson this teaches is that experiments in the way of eliminating inductive effects in nearby circuits should be directed towards evolving an effective method of "damping" instead of neutralizing the induction. Damping prevents or at least tends to weaken such effects in the conductor itself, while neutralization is merely a compensating method which quiets the instruments in circuit and does not attack the cause.

1,002,052. Electric Signaling. To R. A. Fessenden, Brant Rock, Mass.

Personal.

Mr. Frank Kane of Washington, D. C., a well-known old time member of the profession, was a recent New York visitor.

Mr. Harry E. Dunham, formerly associate editor of TELEGRAPH AND TELEPHONE AGE, and now an assistant examiner in the Patent Office at Washington, was a recent New York visitor.

Mr. Arthur Walsh, an Old-Time Telegrapher, and a member of the Society of the United States Military Telegraph Corps, formerly at Auburn, Neb., is now located at Van Nuys, Los Angeles, Cal.

Mr. G. H. Corse, jr., representative of the Chicago, Milwaukee and St. Paul Railway Company at Shanghai, China, was a recent New York visitor. Mr. Corse is on a two months' leave of absence and is visiting various parts of the country.

Mr. F. L. Hutchinson, acting secretary of the American Institute of Electrical Engineers, in place of Mr. Ralph W. Pope, resigned, has been appointed to act as secretary until the end of Mr. Pope's unexpired term, August 1, 1912, or until the earlier appointment of a secretary.

Mr. George E. Hines, of New York, inventor of the improved duplex and quadruplex described in our issue for April 1, has issued a pamphlet on the general subject of multiplex telegraphy, comparing the old methods with his. Mr. Hines' invention is ingenious and is radically different from the quadruplex apparatus in general use.

Mr. Daniel Colestock, a member of the Society of the United States Military Telegraph Corps, and formerly an operator in the Western Union Pittsburgh, Pa., office, and now a retired business man of Titusville, Pa., together with a brother and two sisters, held a family reunion in Alliance, Ohio, recently. The total of the ages of the four survivors is 311 years. Mr. Colestock is vice-president of the Titusville Forge Company.

Dr. A. E. Kennelly, professor of electrical engineering at Harvard University, Cambridge, Mass., and a former telegrapher, sailed on August 26 for Europe. He will attend the meeting at Turin, Italy, of the International Electrotechnical Commission, which will be held in connection with the Turin International Electrical Congress.

Mr. F. J. Hickey an old time telegrapher and for many years past general agent of the Wells Fargo Express Company at New York has been promoted to the general superintendency of the company with headquarters in New York. Mr. C. V. Fowler, also formerly identified with the telegraph, has been made superintendent of the same interests with headquarters in New York.

Postal Telegraph-Cable Company.

EXECUTIVE OFFICES.

Mr. E. J. Nally, vice-president and general manager, has gone on a trip of inspection to Boston, Buffalo and other cities within these limits that will keep him from his office until about September 18.

Among recent executive office visitors were: Mr. G. H. Usher, general superintendent of the southern division, Atlanta, Ga., and Mr. C. K. Hunt of Winsted, Conn.

Mr. Isaac Smith, superintendent of tariff, New York, is absent from his office on a vacation.

Miss T. N. Brown, chief clerk to Mr. E. J. Nally, vice-president and general manager, New York, is on a two weeks' trip to Chicago.

Digitized by Google

This company is installing new and more speedy elevators in its main building, 253 Broadway, New York.

Mr. Lloyd C. McCormick, assistant manager at St. Louis, has been promoted to the position of manager of the Detroit, Mich., office, vice Frank S. Gould resigned.

Mr. William E. Petfield of the South Bethlehem, Pa., office, has been appointed manager at Bethlehem, vice Mr. Charles Anderson, transferred to Philadelphia.

Mr. R. A. Obley, an operator in the Topeka, Kan., office, has been advanced to the management, vice A. B. Matthews resigned.

Mr. L. A. Mitchell, manager of the Jacksonville, Fla., office, ever since the company constructed lines to that city, has resigned to enter the automobile business. Mr. H. R. Waterbury, of the same office, will succeed Mr. Mitchell.

Joseph H. Wentworth, cashier of the Postal Telegraph-Cable Company at Boston, Mass., died suddenly on September 8. He was cashier for the Western Union Company in Boston until 1903 when he entered the Postal company's employ. He was also treasurer of the Martha's Vineyard Telegraph Company at the time of his death.

The following appointments have been made to the new offices in Texas and Oklahoma of the Mackay Telegraph and Cable Company: W. A. Logan, formerly special agent of the Postal Telegraph-Cable Company of Texas, manager at Oklahoma City; T. J. Bolleter of the Postal Telegraph-Cable Company of Texas at Laredo, Tex., manager at Ardmore, Okla.; Watson Dalton, formerly secretary of the Cotton Exchange at Gainesville, Tex., manager at the same place; H. L. Burross, formerly manager of the Western Union office at El Paso, Tex., manager at Fort Worth, Tex., with Joseph Corum, from the Associated Press, as manager of the Cotton Exchange branch office and C. J. Martin of the Texas Postal Company, manager of the stock yards' office at the same point. R. S. Greenwood, of the Western Union Chicago office has been appointed assistant manager at Fort Worth and detailed to outside work. Perry Chamberlain, well known throughout the country and formerly of the Postal Telegraph-Cable Company at New York, is manager at Waco, Tex.; J. S. Lee, former operator and ticket agent for the Cotton Belt Railroad at Waco, is manager at Cleburne, Tex., and A. L. Burge, manager of the Independent Telephone Company at McGregor, Tex., is manager at that point, being assisted by A. Green, operator. Mr. F. C. Lacey has been appointed manager of the Houston, Tex., office. He has been in the service of the Postal Telegraph-Cable Company for over twenty years, at various places, including Peoria, Ill.; Topeka, Kan., and Chicago, Ill.

Mr. Wm. Young Nolly, the new manager of the Dallas, Tex., office of the Mackay Telegraph and Cable Co., was born at Arlington, Tenn., February 15, 1871, and began his telegraphic career in May, 1886, at Little Rock, Ark., on the Iron Mountain Railway. He subsequently held the managerships at Austin, Fort Worth and Dallas, Tex., and Shreveport, La., for the Postal Telegraph-Cable Company, and was afterwards inspector for the Western Union Company for Texas and Louisiana. His wide experience eminently fits him for the duties of his new position.

Postal Telegraph-Telephone Service. — An agreement has just been entered into between the Postal Telegraph-Cable Company, and the Sierra Construction Company which will place a large and prosperous territory in northern California in direct telephonic connection with the system of the Bay Cities Home Telephone Company at San Francisco, Oakland and adjoining cities and towns.

To Enjoin Interference with Telegraph Lines. —The Postal Telegraph-Cable Company has petitioned the federal court at Portland, Ore., for an injunction to restrain the Southern Pacific Railway Company from cutting its wires and disturbing its poles on the railway company's right of way in Oregon.

Western Union Telegraph Company.

EXECUTIVE OFFICES.

Mr. Newcomb Carlton, vice-president of the company, has returned to his desk after a brief vacation.

Mr. A. G. Saylor, general superintendent has returned from a business trip through the eastern states.

Mr. W. H. Baker, vice-president of the American District Telegraph Company of New Jersey, has returned to his office after a vacation spent in the Adirondacks.

Mr. W. E. Athearn, engineer of equipment, New York, has returned to his office much benefitted by his rest at Martha's Vineyard.

Mr. Frank Kitton, assistant to the engineer of equipment, New York, is away on his vacation.

Mr. W. W. Watt, formerly district plant superintendent of the fifth district, Cleveland, Ohio, has been transferred to Chicago as plant superintendent of the first district. Mr. Watt will look after both districts until the vacancy in the fifth district has been filled.

Mr. J. E. Scofield of the Atlanta, Ga., office has been appointed superintendent at Jacksonville, Fla., vice Mr. L. J. Maxwell, who has been attached to the office of Mr. J. M. Stephens, division commercial and traffic superintendent, Atlanta, Ga.

Mr. Ellis Jordan, manager of the Pittsfield, Mass., office has accepted the managership at Tampa, Fla.

Mr. C. W. Chenault, formerly of Lexington, Ky., has been appointed manager at Johnson City, Tenn., vice R. F. Fowler, resigned.

Digitized by Google

Mr. Frank S. Gould, manager of the Detroit, Mich., office of the Postal Telegraph-Cable Company, has been appointed manager of the Grand Rapids, Mich., office of this company.

Mr. Arnold B. Matthews, manager of the Postal Telegraph-Cable Company's office at Topeka, Kan., has accepted the managership of the Western Union office at Great Falls, Mont.

Mr. J. H. Gates, formerly assistant superintendent of the American District Telegraph Company at Columbus, Ohio, is now manager for the Western Union Telegraph Company at Davenport, Iowa.

Mr. L. A. Rudd, manager at Knoxville, Tenn., has been promoted to the management of the Memphis office, and Mr. T. H. Gore, chief operator, succeeds to the management at Knoxville, vice G. E. Woods resigned.

Mr. P. J. Morency, operator for the Oregon Short Line at Salt Lake City, Utah, has been appointed wire chief for the Western Union Telegraph Company at Vancouver, B. C.

Mr. B. F. Ragsdale, chief operator of the Columbia, S. C., office, has been advanced to the position of chief operator at Atlanta, Ga., vice H. K. Griffin, resigned. On his retirement Mr. Griffin was presented with a gold watch and chain by the operating force. He resigned his position at Atlanta on account of his wife's health, and will return to New York, where he will be employed in the quadruplex department.

Mr. F. H. Gournoe, whose appointment as manager of the San Antonio, Tex., office of the Western Union Telegraph Company was announced in our issue of September 1, was born at Euclid, Ohio, May 28, 1874. He began his telegraphic career at Toledo, Ohio, on the Lake Shore and Michigan Southern Railway, and later went to Chicago, where he filled other railroad telegraph positions. Subsequently he was appointed inspector and special agent under Mr. T. P. Cook, general superintendent at Chicago, and was afterward in charge of the overland division in the operating room at Chicago. After a year in this position he was appointed special agent of the Gulf Division at Dallas, Tex., under Mr. L. McKisick, general superintendent, and occupied this position at the time of his recent appointment.

This company is introducing fire drills in all of the large offices throughout the country. The operating department on the eighth floor at 195 Broadway, New York, was cleared in 30 seconds on one occasion and the seventh floor in 32 seconds, and all hands were back to work within one and a quarter minutes. Mr. T. F. Clark of the operating department is the general instructor of the fire drill.

The Cable.

Hon. Thomas Cochrane, of the Direct United States Cable Company, London, England, was a recent New York visitor, coming here on business connected with the service and private interests.

Removal of Cable Office.—The Direct United States Cable Company has moved its main office from 61 to 60 New Street, New York, where a larger space is provided. Mr. Clement Lee is the superintendent.

French Submarine Cables.—The French Cable steamer "Francois Arago" of the Sociéte Industrielle des Téléphones is now engaged in laying cables on the West African coast between Libreville, Cap Lopez and Loango Pointe Noire in the Congo region, to the order of the Ministry of the Colonies for French Equatorial Africa. It is expected that the cables will be laid and open for traffic in October. The total length of the cables is about 600 nautical miles.

Cables Rates.—The Pacific Cable Board in a report to the English Parliament states that a general agreement has been reached, and there is every prospect that within the next few months it will be possible for messages in plain language to be sent at half the existing rates, subject only to the condition that the transmission of them must wait for a period, not exceeding a twenty-four-hour interval, during which the cable is not in use for traffic at ordinary rates.

Municipal Electricians.

Lafayette, Ind.—Improvements are to be made in the fire alarm system in this city.

Police and Fire Alarm.—A police and fire alarm system is to be installed at Tomah, Wis.

Fire Alarm Installations.—The taxpayers of Nyack, N. Y., are to vote on a $7,000 appropriation for the installation of a fire alarm system. The fire committee of Montpelier, Vt., has decided to install a fire alarm system.

New Fire Alarm Indicator.—A new alarm indicator for fire stations is being introduced in Newark, N. J. It has three panes of glass, behind which incandescent lamps can be so arranged as to show the signaling box by numeral or special signs. The apparatus can be worked by hand or automatically by the usual Morse alarm signals. To save the time necessary for finding on a chart the spot from which the alarm was sent, it is proposed to use a translucent map to be illuminated by the alarm, and showing all boxes of the fire department area by numbered disks. The call will also show a red light behind the disk for the signaling box and another for the station, so that the best route to the fire would be seen at a glance.

The Telephone.

Mr. William C. Maas commercial superintendent of the Southwestern Telephone and Telegraph Company at Little Rock, Ark., has been promoted to a similar position covering the Northeast Texas division of the same company, with headquarters at Dallas.

Time by Telephone.—It is stated that 80,000 telephone subscribers in Chicago call up "Central" every day to get the correct time.

Digitized by Google

Improving Telephone Service in Paris.—The sum of $2,333,540 has been appropriated for the improvement and extension of the Paris telephone system.

Wireless Sea Telephone.—Mr. A. W. Sharman of London, England, has invented a wireless telephone by which, it is asserted, talking from one vessel to another in mid-ocean will be possible.

Telephone Bond Issue.—The Southern Bell Telephone and Telegraph Company has filed a trust deed in Georgia, Florida, Alabama, North Carolina, South Carolina and West Virginia covering a $50,000,000 bond issue. The bonds will mature January 1, 1941.

Telephonic Communication Between European Capitals.—There is a prospect that telephone communication between London and Berlin will soon be an accomplished fact. The new service, it is stated, is dependent upon a new land line which the French authorities have under construction to the German frontier, and when this is completed and linked up with the German line there will be direct communication between Berlin and London via the new cable which has been laid across the Channel by the British Government. There is also said to be a project on foot to establish a telephone line between Berlin and St. Petersburg.

The Early Days of Telephony.—The *Telephone Review* for August contains reproductions from the *Poughkeepsie Eagle* of October 24, 26 and 29, 1877, of accounts of the introduction of the telephone in that city. The line ran from the Atlantic and Pacific Telegraph office to Eastman College and the tests in the telegraph office were conducted by Mr. Frank C. Mason, formerly superintendent of the Fire Alarm and Police Telegraph in Brooklyn, N. Y., who was the operator in the Poughkeepsie office at that time. According to the accounts the tests were successful and it is recorded that an application was made by James Hyatt, of Bagnall, to have a telephone line connect his residence with the railway depot at that place.

President Vail on the Cable Situation.

Mr. Theo. N. Vail, president of the Western Union Telegraph Company, New York, has issued the following statement in regard to the trans-Atlantic cable situation:

A provisional modification of an arrangement which has existed for many years has been reached between the Western Union Telegraph Company, the Anglo-American Cable Company and the Direct U. S. Cable Company, under which the cable systems of these companies now worked exclusively in business connection with each other, but operated and maintained separately, will be operated in direct physical connection with each other and with the Western Union land system.

Two objects are to be attained by this arrangement:

First, more efficient and economical operation.

Second, the introduction of new forms of service to the advantage of the public.

The trans-Atlantic cable situation is as follows:

The Mackay group of seven cables, including the German cables, owned by or worked in physical connection with the telegraph lines of that company form one system.

The French cables comprise an independent system, using both the Western Union and the Mackay land lines for their United States connection.

In competition with these is the Western Union group of cables, eight in all, owned by three separate companies, two of which are British companies owning five of the eight cables.

Two only of the British owned cables terminate in the United States and all of them are entirely dependent on the Western Union for their connection with any telegraph system, or for their reaching any center of business, and are now worked exclusively, so far as business is concerned, with the Western Union.

The proposed arrangement between the Western Union, the Anglo-American and the Direct U. S. companies will bring the eight cables of the three companies under one operating control. The consequent increase in effectiveness and economy will place the Western Union in a position to offer certain advantages in cable service not now enjoyed by the public.

The other way open to enable the Western Union to make such improvements and introduce such new services as it proposes to do, would be to lay new cables. This would seem to be the height of folly. Duplication of the existing trans-Atlantic cable facilities at a cost of many millions, when there are more than ample facilities for all business, would put an unnecessary financial burden upon an already fully burdened business and would probably postpone the reduction of rates or introduction of new services.

As at present carried on, the trans-Atlantic cable business is practically all flash service, i. e., instantaneous. Owing to the difference in time, there are only a few business hours of the day common to both sides and during these hours at least seventy-five per cent. of the cable business is done.

In the interests of international business nothing should be done to interfere in any way with the so-called flash or instantaneous service, and the lines should be kept clear to accommodate such messages during the few business hours common to both countries; but to continue to confine the cables to this class of service, as at present, will utilize only about twenty-five per cent. of the existing capacity of millions of property and places on that limited service all the capital, maintenance and operating charges.

The limited time and the character of the business, if best results are to be obtained, demand direct cable circuits between principal centers of

Digitized by Google

the two sides of the Atlantic, as well as special circuits devoted to special business.

To meet these requirements it is essential not only that there be at all times sufficient cable facilities, under one control, but that they should be operated interchangeably with each other and in close physical connection with land lines as one system. Ample spare facilities are necessary to provide against the very frequent cable interruptions.

Neither the Western Union nor any one of the companies of the Western Union group has, independently of the others, facilities enough to handle the business which at times any one company might be called upon to take care of, because of some particular rush of business, or because of some cable interruption. Nor could any one company furnish all the direct circuits necessary for efficient service, although the combined facilities of these companies are ample if they could be used supplementary to each other and interchangeably.

As it is, each company operates its own cables through separate and distinct offices and under separate and distinct management. All interchange of business is by actual transfer of the business from one company to the other, with the consequent delay and interruption of a service in which seconds are valuable.

So soon as the proposed arrangement goes into effect, the Western Union purposes, with the consent of the British Post Office Department, to introduce at least two new features or services in addition to the proposed deferred rate—the Daily Cable Letter and the Week-End Cable Letter—at a very low rate for cable service only. This will enable the public to save the six to eight days consumed in the trans-Atlantic passage of mails.

There is no cable monopoly possible. The three systems—the Western Union, the French and the Mackay—will continue to exist.

The Mackay Companies is a holding organization with no physical property, but exercising through stock ownership, lease or contract, operating control of various companies owning land lines and cables which make up the Mackay System. Through this control all the various properties are operated as one system to great advantage in service over what could be given by these same companies if operated separately.

The French cables form another system.

The Western Union system, under the proposed arrangement for one operating control over the present segregated units, will be enabled to make two distinct advances in the trans-Atlantic cable business:

1—*Better Service.* This will be insured by more efficient and economical working resulting from single direction over the operations of both cables and land lines.

2—*Public Advantages.* The greater part of the cable capacity has been and is now unutilized. It will continue to lie dormant and unutilized under existing conditions and traditions. The Western Union purposes to make these wasted facilities useful to the public by means of new kinds of cable service.

In addition, the Western Union intends to nationalize its land lines by opening them to all trans-Atlantic cable companies.

Obituary.

Anthony F. Saunders, aged 53, operator at Kansas City, Mo., died August 10.

Henry Griffith, aged 62, formerly an operator at Augusta, Ga., and later of Baltimore, died in the latter city August 12.

Capt. John C. Butler, aged 79 years, died in Macon, Ga., recently. He was one of the oldest telegraphers in the South.

Mrs. J. B. Dillon, wife of Mr. J. B. Dillon, wire chief of the Western Union Telegraph Company at Dallas, Tex., died at Galveston, Tex., August 21. The remains were taken to Louisville, Ky., for burial.

Chris Reilly, aged 59 years, an old operator, died at Memphis, Tenn., recently. He was an associate of Mr. Thomas A. Edison in the early days when Mr. Edison was employed in the Western Union office at Memphis.

Clarence Cary, aged 65 years, a prominent New York attorney, and for many years previous to 1892 general attorney of the Western Union Telegraph Company, died on August 27, at Greenwich, Conn. Deceased was born in Fairfax County, Va., and during the Civil War served in the Confederate army and navy.

M. Ernest Mercadier, a well-known telegraph authority in France, died in Paris July 27. He was Director of Telegraphs during the siege of Paris, and after the war became professor of physics at the High School of Telegraphy. In 1891 he became director of studies at the Polytechnic School. He was the author of many technical works.

Mrs. Samantha F. Berniholtz, who was chief operator at Gettyburg, Pa., at the time of the battle at that place during the Civil War, died at Waynesboro, Pa., September 10, at the age of 75 years. During the battle of Gettysburg she sent many important official telegrams to the War Department at Washington from commanding officers in the field.

General J. E. Tyrrell, for forty years identified with train dispatching on the Michigan Central Railroad, at Jackson, Mich., died at that place August 8, aged 64 years. For twelve years General Tyrrell was at the head of the Michigan state militia. He had a very eventful career. He took part in the Fenian uprisings in Ireland in 1867; was captured, but through the intercession of friends was released. He came to America with his parents in the early fifties and later learned telegraphy. He also took part in the Civil War and the Spanish-American War. The degree of perfection to which the militia of Michigan has been brought was entirely due to the efforts of General Tyrrell.

Landing the First Successful Atlantic Cable.

The accompanying illustration is a reproduction of an old print in the possession of the Western Union Telegraph Company at New York, and represents the scene at Heart's Content, N. F., on the landing of the first successful Atlantic cable on July 27, 1866. The following account of the event, taken from Field's *History of the Atlantic Telegraph*, is published in the *Journal of the Telegraph*, together with the illustration.

"On Friday morning, July 13, 1866, the fleet finally bade adieu to land (Valentia, Ireland). Was Friday an unlucky day? Some of the sailors thought so, and would have been glad to leave a day before or after. But Columbus sailed on Friday and discovered the New World on Friday, and so this expedition put to sea on Friday, and as a good Providence would have it, reached land on the other side of the Atlantic on the same day of the week.

"It is Friday morning, the 27th of July (1866). They are up early and looking eastward to see the day break, when a ship is seen in the offing. She is far down on the horizon. Spy glasses are turned toward her. She comes nearer—and look, there is another and another. And now the hull of the Great Eastern looms up all glorious in that morning sky. They are coming. Instantly all is wild on shore. Boats put off to row toward the fleet. The Albany is the first to round the point and enter the bay. The Terrible is close behind. The Medway stops an hour or two to join on the heavy shore end, while the Great Eastern, gliding calmly in as if she had done nothing remarkable, drops her anchor in front of the telegraph house, having trailed behind her a chain of 2,000 miles to bind the old world to the new.

"Although the expedition reached Newfoundland on Friday, the 27th, yet as the cable across the Gulf of St. Lawrence was broken, the news was not received in New York till the 29th. It was early Sunday morning, before the Sabbath bells had rung their all to prayer, that the tidings

SCENE AT THE LANDING OF THE FIRST SUCCESSFUL ATLANTIC CABLE.

came. The first announcement was brief:

"'Heart's Content, July 27.—We arrived here at nine o'clock this morning. All well. Thank God, the cable is laid and is in perfect working order.

"'(Signed) CYRUS W. FIELD.'"

Brazilian Telegraphs.—The Ministry of Communications and Public Works, of Brazil, is to spend about $180,000 for the construction of a building intended for the Postal telegraph office in Nictheroy, State of Rio de Janeiro.

Report on Electrolysis.—The Chicago Board of Public Efficiency has issued a report on electrolysis of water pipes. It contains much information on the subject and will be of interest to telegraph and telephone men.

The Mercadier-Magunna Multiplex Telegraph System.

The Mercadier-Magunna multiplex system of telegraphy has been tested under the direction of the French government over a line between Paris and Lyons, a distance of about 280 miles. The system is described by Mr. C. L. Durand, in *Electrical Review and Western Electrician.*

On the occasion of the test a quadruplex Baudot printing telegraph of the government type was operated by direct current along with a sextuplex Hughes printer by vibratory currents, making five transmissions each way. Counting each Baudot instrument at 1,550 words per hour and a Hughes instrument at 1,800, the total is 10,800 words per hour. On the usual direct-current method, only the quadruplex Baudot method can be used, so that the capacity of the line is nearly tripled. With Morse sounders or tape receivers the advantage is still greater, and the line will carry four times the usual number of messages.

The Mercadier-Magunna system depends on the use of vibratory transmitters sending alternating current on the line, each at a standard frequency. At the other end is a set of selective receivers, so that each current is received in a separate instrument. Three messages can be thus sent each way in practice. However, this does not prevent sending messages at the same time by the usual direct current, as alternating and direct current are sent over the same wire by using the Van Rysselberghe connection. With the Morse signals the difficulties are even less than with printing telegraphs such as are used in Europe. Given a line which is duplexed as usual on direct current, three messages each way can be added by using the vibratory method, that is, six messages counting both ways. The capacity of the line is now eight messages against two on the usual method. The new apparatus has very little complication, and another point is that none of the regular standard instruments such as sounders, etc., need to be modified. Dots and dashes are sent by key in the same way as before. Where alternating currents are used on the line, the signals are always received as direct current, by the use of relays and local battery circuits.

The transmitter uses a tuning fork which is kept in vibration by an electromagnet placed between branches. One wire of the magnet is connected to one pole of a storage-battery and the other wire to the metallic mass of the fork. Each prong of the fork carries a contact by which the circuit is broken in the usual way by the action of the magnet upon the prongs.

One of the interesting points about the system is the use of a special type of vibrating receiver in order to select the waves of different frequencies which are sent over the line. The inventors designed a receiver which they call "mono-telephone" on account of its resemblance to a telephone. It uses a metal disc which is made to vibrate by the action of an electromagnet, but it differs from the usual telephone principle from the fact that it will be set in vibration by only the waves of the exact pitch for which it is tuned. For instance one of the monotelephones is tuned so as to respond when the operator sends signals by using waves of a frequency of 575, but for other waves it produces no effect whatever.

In designing such instruments, the inventors make use of the properties of vibrating plates. When a metal plate is placed horizontally and is sprinkled with sand, and the plate is then made to vibrate by striking the edge, the sand is driven off from some portions and is collected upon others. The sand tends to collect upon the nodal lines, where the vibratory movement is zero and on the contrary it is driven away from the strongly vibrating parts. The form of the nodal lines depends upon how the plate is vibrated. Should we vibrate a circular plate by means of an electromagnet placed under the center, we obtain a circular nodal line which corresponds to the first harmonic of the fundamental tone of the plate. Should we now fix the plate by three supporting points lying on the nodal line, such a plate will vibrate at only the pitch corresponding to the first harmonic, and for any other pitch it will be silent. The plate is made to vibrate by mounting a soft-iron disk armature at the middle and placing an electromagnet underneath. Such a disk, can be made of steel, copper, silver, etc., and it is held by three screws upon sliding supports so as to hold it on the base and also leave it free to vibrate. Under the plate is a specially annealed soft-iron disk which is acted upon by an electromagnet. Around the iron core is a concentric soft-iron ring and below is a permanent magnet which is placed so as to magnetize the soft iron parts and form an annular magnet having an equal circular distribution of the lines of force. The magnetic circuit also includes the armature. It is found that such a method is the best for securing the vibration of the disk when the coil receives alternating current. The pitch of the disk depends on its diameter, so that each monotelephone uses a disk of different diameter. The diameter of the nodal line is 0.64 of the diameter of the plate. Such plates are adjusted to the exact pitch by comparing a set of standard tuning forks, and they will respond strongly for a current of the right pitch, but are inactive when the current differs from this by only a small amount, so that the monotelephones form a very sensitive selecting system. Such monotelephones could be used to hear the messages by sound, but it was desired to make them act as relays in order to operate printing telegraphs or Morse tape. On the disk is soldered a platinum plate upon which bears a contact point carried on the end of a lever. The lever is mounted on pivots and the pressure at the contact is adjusted by a counterweight. When the disk vibrates, the lever which

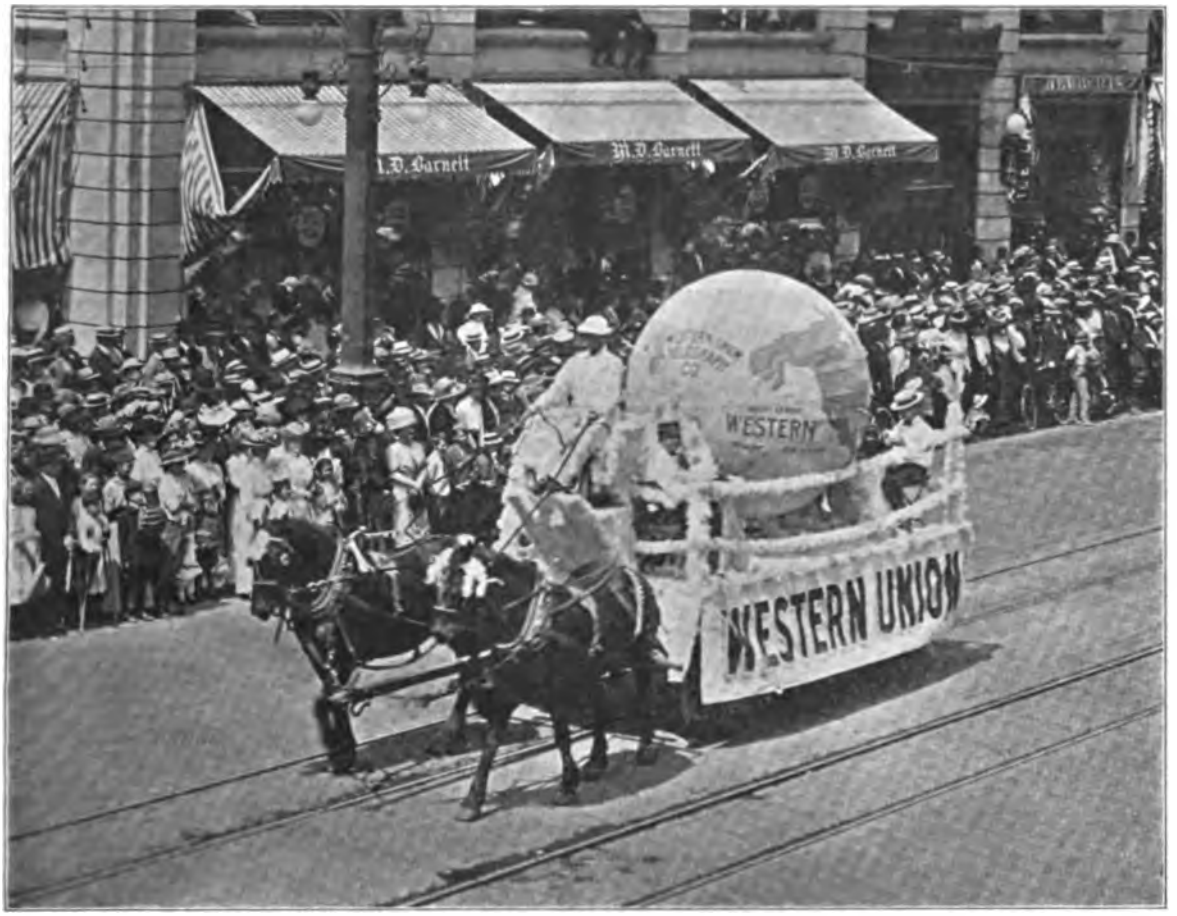
Digitized by Google

has been so adjusted that its natural vibration is much slower than that of the plate, is unable to follow the vibration of the disk, so that there is a considerable increase in the resistance at the contact of the lever and plate. A direct current passes through this contact for operating a local relay, and the adjustment is such that when the current is diminished the relay will make contact and thus operate a Morse receiver or a printing telegraph. Each signal sent over the line by alternating current gives a like signal in the direct-current receiver.

To secure a better operation, the tuning forks are given a different pitch from the corresponding receivers in the same station, and the difference between the highest and lowest pitch is lessened as much as possible without interfering with a good selection by the monotelephone. In fact the compensation is only approximate when different frequencies are used and is only exact for one given period, so that it is required to work with frequencies lying as near together as possible. These are chosen at 575, 725 and 875 for the transmitters and 500, 650 and 800 for the receivers of the same station.

Western Union Float in Denver Parade.

The accompanying illustration shows a float representing the Western Union Telegraph Company, which formed a feature of the recent industrial parade in Denver, Col. The globe was constructed of canvas drawn over a framework, eight feet in diameter, the western hemisphere being shown on both sides. On the North American continent Denver was represented as the central point from which lines radiated in every direction. The maps were executed in the company's standard colors, white and blue. The telegraph lines were shown in tinsel, and ropes of flowers outlined the float. At the four corners of the float were operators, each being provided with a set of instruments and a typewriter. They alternately sent and received messages while the parade was in motion. The four operators were A. F. Felder, E. L. Whitbred, A. Fried and M. E. Tierney.



WESTERN UNION FLOAT IN INDUSTRIAL PARADE, DENVER, COL.

We are indebted to Mr. J. C. Nelson, general superintendent, Denver, Col., for the photograph of the float and the facts given herewith.

Instruction in Wire Patching.

BY B. D. SNYDER, DALLAS, TEX.

There has been much said and done for the improvement of the various departments of the telegraph service, but there is one department that does not appear to have received its proportionate attention.

Experience shows that there is a lack of interest taken in the instruction of young men and women, and some of the older ones, too, assigned to testing offices, in the matter of making tests and patches of the various circuits passing through such offices. At any time a wire chief may be called upon to test or patch a wire at any office in his jurisdiction. It is his duty to get defective circuits into workable condition, but when he has to deal with an attendant at a test office who does not know how to make a simple test or patch much valuable time is lost in giving detailed directions over a wire. It consumes anywhere from ten to thirty minutes to give such instructions, when the work should be accomplished in a few minutes.

I believe that a method of instructing those who are assigned to such offices in test and patch work would be a move in the right direction.

As a suggestion I might offer the following as one plan to meet the situation: Have a print made of a 20-strap board with the most numerous patches and tests shown on it, also a set of small illustrations showing how and telling why each one is made, and have them so numbered that a wire chief can direct the test office what test or patch to make simply by giving the number of the chart to follow. The charts and printed instructions should be kept beside the switchboard and the manager held responsible for them just as he is for other pieces of office property.

A Novel Cause of Wire Trouble.

Mr. R. H. Tudor, manager of the Western Union Telegraph office at Chattanooga, Tenn., reports an amusing case of wire trouble on a line between that city and Dalton, Ga.

One of the trunk lines became grounded and a lineman was immediately sent to clear the trouble. He found it just north of Dalton. A farmer living near the railroad had been experiencing considerable trouble with his mules and his wire fence. The mules were in the habit of rubbing against the fence, thus pushing the posts down and getting out on the railroad tracks. Being somewhat of an electrician the farmer tapped the wire and connected it to the top wire of his fence, in order that the mules might receive a shock, the idea being to thus keep them away from the fence.

When asked by the lineman what he meant by grounding the wire, the farmer replied: "I didn't know it would interfere with you fellers sending telegrams. I just merely wanted to protect my mules from the railroad." He promised, however, that he would string a barbed wire around his farm and "shock" his mules in a different manner.

[No doubt many curious experiences of this nature are met with throughout the country and if anyone knows of such we would be glad to have an account of them for publication as a matter of general interest.—Ed.]

Telegraphers of Today.

An excellent opportunity is offered to telegraph people in general to become acquainted with over 600 prominent telegraph officials and others identified with the telegraph, the railroad, the submarine cable service and press associations of the past generation, through their portraits and sketches of their careers as published in "Telegraphers of Today."

This work was issued in 1894 and includes biographical sketches of all the individuals connected with the interests mentioned at that period, many of whom have passed away from their earthly labors. The younger generation, however, will find much of interest in looking upon their portraits and reading of their achievements in life. Many of them are still alive and in harness, in the telegraph and other fields of activity.

This book, which is 11½ x 14 inches in size, was originally published at $5 per copy, but in order to close out the remaining copies we offer them at $1 per copy by express, charges collect.

Send orders to TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

Fireproof Varnish for Insulation.—A French patent describes a fireproof varnish for insulation. A solution of cellulose acetate in tetrachlorethane and pyridine forms a substitute for rubber varnish for electric wires. Its viscosity can be increased if necessary by the addition of hexachlorethane or aldehydes of the terpene series. This varnish can be used for flame-proofing textiles and for insulating tinfoil in electrical condensers.

Ordering Literally.—In the printed circulars relating to word counters it is requested that customers mention, when ordering, the type of make of their machine. An order was recently received with the information that the type of the machine was pica, and he wanted a word-counter with attachment to fit the same.

Squirrels Housekeeping in Cable Box.—The circuits in a telephone cable in Great Barrington, Mass., became "noisy" recently. Investigation disclosed a family of squirrels in a cable box, the occupants having pulled off the insulation around the wires for their nest.

Electrical Assessments in California.—Among the assessments of electrical properties in California the telegraph is placed at $25,160.20 and the telephone at $399,594.74.

Fire Drill in Large Telegraph Offices.

The Western Union Telegraph Company has inaugurated a fire drill in its large offices throughout the country and it cannot be questioned that this is one of the most important steps taken by the company for the protection of the lives of its employes.

In the event of a fire or any other cause for alarm where there are many people congregated, and they become panic-stricken, the loss of life which usually ensues is due very largely to the disorder resulting from the unorganized effort to escape from danger. It is generally recognized that the application of system and order in any line of activity produces the best results with the least amount of friction and loss of time. The same idea is applicable to the handling of human beings collectively as well as individually.

Regular training to perform certain acts under assumed emergency conditions, is the best means of preventing disorder and panic in times of actual emergency, and this is what is being done by the telegraph company. On a prearranged signal every employe in the room opens his or her key, stands attention and awaits orders from the division traffic chief. On order they all march to the exits and other places of safety. This is all done in an orderly manner, and everyone is enabled to escape with the least confusion and in the least possible time.

In the practice drills, signals call all hands back to their desks. In the New York office one floor of the main operating department has been cleared in thirty seconds and within one and a quarter minutes from the sounding of the first signal every employe was back to work. This is remarkably quick time for such an action, and it augurs well for those most deeply concerned in case an actual emergency should arise. The company is to be commended for its humane attitude, and it is to be hoped that this innovation will prove to be a case of an ounce of prevention being better than a pound of cure.

The Atlantic City Reunion of Old Timers.

In respect to attendance and enjoyment the reunion of the Old Time Telegraphers' and Historical Association and the Society of the United States Military Telegraph Corps at Atlantic City on September 5, 6 and 7, was a great success, and the members, their families and friends have reason to regard their visit to this famous seaside resort on this occasion as a real "bright spot" in their lives. It would do us all good if we had more such "spots" in our experiences. Telegraphers, even those of the old time variety, are hard workers, and such outings are beneficial all around.

The mind requires variety of thought-food as much as does the body physical food, and a change of thought-food is as helpful to the body as is the other kind.

An interesting feature of the meeting was the presence of Mr. E. L. Morse, a son of the inventor of the telegraph, and the old timers naturally took particular delight in honoring this distinguished guest. The great achievement of his father is one of the most powerful agencies in the world to-day in uniting the widely separated peoples of the earth into one great family and contributing to their comfort and knowledge. Indeed, the reunion itself was an indirect result of Professor Morse's work, for if the telegraph had not been invented there would be no old or young timers, and no occasion to gather together as a united body representing one of the greatest industries in the history of the world.

An Effect of the Messenger Boy Law in Massachusetts.

An interesting situation has developed in Massachusetts as a result of the recently enacted law prohibiting the employment of messenger boys under the age of 21 after 10 p. m. While the telegraph companies are alive to their obligations to the public and to the provisions of the law, they have decided to curtail the delivery service after that hour in places where it does not warrant the necessary extra expense to carry out the legal requirements.

Messages received after that hour addressed to persons having a telephone on their premises can be forwarded to their destination by this means, but those which cannot be so dispatched may be held for delivery next morning.

Some means will undoubtedly be provided for the delivery of urgent messages at any time, whether the addressees have a telephone or not, for the idea of keeping a telegraph office open for the reception of messages and providing no means for their delivery would be rank inconsistency, and certainly the telegraph companies realize that. The law may be particularly onerous, but the telegraph companies will surely find a way to meet the situation and fulfill their obligations to the public.

Causes of Losses in British Telegraph Operation.

In a recent speech in the House of Commons, London, on the subject of government telephone control and operation, Sir Herbert Samuel, postmaster-general of Great Britain, gave some of the reasons why the English telegraph system lost $5,000,000 a year.

"It has been stated," he said, "that the post office is not to be trusted with the management of this business (telephones) because post office inefficiency has been proved by the fact that our telegraphs are worked at a loss which now amounts to about £1,000,000 ($5,000,000) a year. The loss on the telegraphs is due to four causes.

"In the first place there are the low press rates which are quite unremunerative, and which were granted by Act of Parliament at the time of the transfer of the telegraph business to the state. These very low press rates account for a loss of about £200,000 ($1,000,000) a year, and it is sometimes amusing to read newspaper articles asserting that the inefficiency of the post office is proven—when the fact is that under parliamentary pressure we gave unduly low press rates—and that therefore the telephones ought not to be entrusted to our hands. These same newspapers are at the moment enjoying the unremunerative rates which they would be very unwilling to surrender.

"Secondly, we have deliberately extended the telegraph system in the rural districts for general purposes of national development in a way that a commercial company would not have done. It has been done with the sanction of Parliament and by various governments with their eyes open, knowing that a loss would accrue, but believing that it was well to spend some part of our postal surplus in incurring that loss rather than leave the rural districts unprovided with telegraphic facilities.

"Thirdly, when the telegraphs were on the point of paying their way, and when the earlier deficits were being made good, the House of Commons stepped in and rejected, a good many years ago, the advice of the postmaster-general of that day, and insisted on a system of six-penny telegrams which are in very many cases unremunerative, and which account for a considerable portion of the loss. But even six-penny telegrams might have been made to pay in the course of time, if it had not been for the intervention of the fourth consideration, namely, the development of the telephone itself, which has been actively fostered by the post office, and the effect of which has been to take away a most remunerative part of their business—the short-distance telegrams between different parts of the same towns.

"Telegraphy has completely altered its character in recent years. The bulk of the telegrams used to be telegrams dispatched short distances, but now the bulk of telegrams are becoming more and more telegrams which are sent over long stretches of the country, and which are not of a remunerative character at the six-penny rate. When the average cost of dealing with a telegram now as compared with twenty years ago is considered, you find that a telegram dealt with now is a different thing from what it was twenty years ago, owing to the advent of telephony. The fact that there has been a loss on the telegraphs is not due to inefficiency, but is owing to the operation of these four reasons.

"While the telegraph system does not pay, I think the House of Commons would prefer that there should be a loss paid out of the postal surplus than that either the press rates should be raised or that the country districts should be without facilities, or that the six-penny rate should be increased, or that the substitution of telephony for telegraphy should be hampered."

Telephone Dapartment at Buckingham Palace.

The telephone department at Buckingham Palace, London, the city residence of King George, has been remodeled and brought up to date. During King Edward's time this department was of the most primitive description, but King George appreciates the value of the telephone and uses it constantly, day and night.

The general post office has installed a special exchange in the palace with three fifty-line switchboards, two for day and one for night service. There is an extension from the switchboard to the king's private apartments, and in addition the king has a private exchange line of his own which is used for specially private conversations on affairs of state with cabinet ministers and high officials.

There is also a private wire to Windsor Castle and to the residence of Lord Knollys, Sir Arthur Bigg and other court officials, to Marlborough House, York House, the residence of the Duke of Connaught, and St. James Palace.

The most extraordinary precautions have been taken to prevent these private conversations from being overheard. The king's number, which is, of course, not made public, is "832 Westminster," but any one who expected to "get through to the king" by calling up that number would be disappointed.

Queen Mary, in addition to the same facilities, has a private line from her boudoir to the children's schoolrooms, and she, too, uses the telephone on every possible occasion. King George frequently gets through a lot of business on the telephone before he goes out at 9 o'clock for his ride in Hyde Park.

Delivery of Messages in Georgia.—The Georgia Railroad Commission proposes to adopt a rule requiring all telegraph companies to deliver day messages within one hour, if the addressee lives within the corporate limits of the town where the message is received, and all night messages by nine o'clock the following morning. The telegraph companies will be permitted to deliver such messages by telephone upon written request of the sender or addressee.

Standardization Rules.—The August transactions of the American Institute of Electrical Engineers contains the standardization rules of the Institute adopted June 27. The rules are very complete.

The New Telegraph and Telephone Building in New York.

The site for the new building to be erected on Walker and Lispenard streets, New York, for the joint use of the American Telephone and Telegraph Company, the New York Telephone Company and the Western Union Telegraph Company, has been cleared and work is now progressing on the foundations.

The assignment of space in the building will be about as follows:

The Western Union Telegraph Company will occupy the eleventh to the sixteenth floors inclusive and half of the seventeenth floor, which will be used as a restaurant for the employes.

The American Telephone and Telegraph Company will occupy the third, fourth, fifth and part of the sixth floors, chiefly for the installation of its new long distance toll board. This will be the largest 'ong distance board in this country, having approximately two hundred operators' positions. Part of this board will be located on the fourth and the remainder on the fifth floor, the third floor being used as a terminal room.

The New York Telephone Company will use the remainder of the building for offices for the various departments.

The building has been planned with a view to meeting the requirements of the three companies for about eight or ten years.

While no local switchboard will be installed in the initial building, it is the intention later, when additional stories have been added, to install two or possibly three local switchboards which will be capable of furnishing service to approximately 60,000 stations.

It is proposed to finish the roof of the building in order that it may be used as a roof garden.

The building will have an ultimate height of twenty-four stories, but for the present only seventeen stories will be erected. The estimated cost of the initial building will be about $1,730,000, and it is expected to have it ready for occupancy about June 1, 1912.

A description and illustrations of the building were given in our issue of February 16.

ANSWERS TO QUESTIONS.

[In this department questions on matters of a practical character, and of general interest, will be answered. Questions intended for this department must be signed by the writer's full name—not for publication, but for identity. No attention will be paid to anonymous communications.]

(64) Q. Do all liquids conduct electricity to the same degree? A.

A. No; there is a vast difference. Liquids may be divided into three classes as to electric conductivity: First, those which do not conduct at all, such as turpentine, petroleum and many oils; second, those which conduct without decomposition, such as mercury and other molten metals which conduct as solid metals do, and, third, those which are decomposed when they conduct a current, such as dilute acids, solutions of metallic salts and certain fused solid compounds.

(65) Q. Does magnetism act through water, and is there any substance that will stop the magnetic lines from passing through? S. T. W.

A. Magnetic action takes place across glass, wood, paper, water and all other substances except iron. The magnetic lines are absorbed by the iron, and this fact is utilized in the construction of ammeters and voltmeters that are to be exposed to external magnetic fields. The iron case of the instruments protects the mechanism from magnetic influences outside of the case.

(66) Q. Is there any distinction between a magnet and a magnetic substance? B. A. M.

A. Yes, there is a decided difference. A magnet attracts only at its poles, but a piece of iron will attract either pole of a magnet, no matter what part of the iron is presented to the magnet. It has no fixed poles. The iron is therefore a magnetic substance.

(67) Q. Does change of temperature have any effect upon the output of a battery? D. C.

A. Yes. If a cell be warmed it yields more current than when cold. This is chiefly due to the fact that liquids conduct better when warm, the internal resistance being thereby reduced.

(68) Q. Is there any way to measure the strength of the distant battery in quadruplex operation? B.

A. In Jones's Pocket Edition of Diagrams there is a rule for measuring the strength of the distant battery, but the explanation is too lengthy to be given in this column. It will be found on page 63 of Mr. Jones' book.

(69) Q. In wireless telegraphy are received signals always of the same power? S. A.

A. No, they vary a great deal. Inaudible signals often become strongly audible in a few seconds. They may remain so for a few seconds and eventually die away. This phenomenon is called "swinging" and is supposed to be due to changing conditions of the atmosphere. A very interesting article on the effects of sunlight on wireless transmission was printed in our issue of September 1. It gives a great deal of information on the peculiar actions of wireless signals.

Mr. George F. Bassett of the commercial department of the Western Union Telegraph Company, Chicago, Ill., in a recent letter writes: "I want to take this opportunity of expressing my appreciation of the excellence of TELEGRAPH AND TELEPHONE AGE. It is certainly keeping up with the times in quality and in style and I do not see how any telegrapher or electrician who desires to progress in his profession can get along without it."

Wireless Telegraphy and Aeroplanes.

The applications of wireless telegraphy are now so widespread that much progress has been made in directions which, in the ordinary way, receive but little public recognition. One of these applications is in telegraphing from aeroplanes and airships. The advantage of being able to communicate with land or other stations was well exemplified in the case of the Wellman flight, and the gain to a military aeroplane scout in being able to send messages to his army is obvious. With the aeroplane the weight of the apparatus is important. A long aerial wire, though a necessity where distances of any length have to be covered, is almost out of the question. Many experiments have been conducted with long aerial wires trailing behind an aeroplane, and distances of a few miles have been covered by that means. In experiments carried out with Mr. McCurdy's aeroplane in the United States only one long wire was employed, the steel wires of the machine itself being used as a counter-capacity. The idea of employing the network of wires on the aeroplane is, however, impracticable, as they become "alive," and might give serious shocks to the pilot or passenger. Two long wires appear to be the simplest solution of the problem, but trailing wires present dangers in so many ways to a machine travelling at a high speed through the air that pilots might rarely consent to their use.

In a lecture before the Royal Institution, London, Mr. T. Thorne Baker passed in review some of the work already accomplished in the application of wireless telegraphy to aerial navigation and referred to some satisfactory results obtained by Mr. Farman by using two trailing aerials, each consisting of rather thin wire about one hundred metres in length. Those experiments were carried out some time after Mr. Baker had adapted a similar arrangement to a Bristol biplane in England. In the latter case no loose wires were used, and thus he had been limited to the amount of aerial that could be attached to the machine itself—about fifty feet. Instead, however, of using balanced aerials, he coupled them to each end of an inductance coil, and increased their effective length to the greatest extent possible without sacrificing efficiency. In the latest form of the apparatus he was using a 6-in. induction coil with a ⅝-in. spark gap, fixed at a considerable distance from the apparatus, so as to be away from the petrol tank. Two light brass rods extended from the coil well into the space between the two main planes of the machine, and to one side of the tank, and two ⅜-in. brass rods sliding over these and ⅝-in. apart formed the spark gap terminals. Shunted across the spark gap was a condenser of the Leyden jar type, and an inductance coil consisting of seven turns of No. 14 copper wire wound on a light ebonite drum. This inductance had sliding contacts so that the number of turns used could be varied in the usual manner, in order to tune the two circuits. The two aerial wires were connected to the two ends of the inductance in use, and the aerial circuit was brought into tune with the shunt circuit. A secondary battery of eight or ten volts supplied the primary energy, about fifty or sixty watts being required.

Two new arrangements have since been adopted, which should greatly enhance the efficiency of the plant. The chief of these is a long light brass tube attached to, but insulated from, one side of the tail of the aeroplane. This acts as a counter capacity, or "earth," to a long aerial wire on the other side. This aerial starts from the nose of the machine, is carried thence to the extreme outer edge of the main plane, thence back to the tail, and thence to a loose extension, a length of sixty feet of copper wire trailing behind.

Much attention has been given to the problem of receiving wireless messages on aeroplanes. For an aeroplane scout to be able to communicate with his commanding officer is, of course, of primary importance, but it would be of immense advantage if he could exchange messages or receive commands. The chief difficulty is that of noise. A visible method of receiving must perforce be selected. Mr. Baker suggests an arrangement in which a coherer is fitted up to the aerials, with a tuning condenser shunted across it, and every two seconds the coherer is automatically decohered by a striker actuated by a magnet excited by a clockwork contact maker. A relay and battery are connected in series with the coherer, and the local circuit of the relay is connected with another battery and electric lamp. Each time a signal is received the lamp lighted up—for one second in the case of a dot and for two seconds in that of a dash. These long signals are obviously necessary, but in spite of that a message can be sent with reasonable rapidity.

An alternative means of receiving on an aeroplane is to use an inker, and this method again requires the employment of the coherer. The inking apparatus is heavy, however, and requires fairly careful adjustment, so that it is rather unsuitable for use where there is much vibration. The question of vibration is a serious one with the ordinary coherer, for if mechanical decohesion is very rapid, it might be impossible to make the coherer work long enough to get the local side of the relay to work effectively. The actual number of impulses per second in an aeroplane traveling thirty miles per hour, with a Gnome seven-cylinder engine, is on the average too great for the coherer to act. In that case it becomes necessary to employ an anti-vibration holder to take off the abruptness of the shock, or a coherer which is insensitive to the abruptness of the shock.

Wireless telegraphy from balloons and airships has reached a more satisfactory stage. Of first importance is the ability to suspend a long wire from the balloon, and next the weight-carrying capacity of the balloon itself. The apparatus used in the Beta military airship weighed roughly 100

Digitized by Google

pounds and signals had been transmitted, under favorable conditions, a distance of about fifty miles, so that the ratio of weight to distance of transmission was roughly two pounds to the mile. An ordinary induction coil and accumulator had so far been used in the experiments and one trailing aerial wire and a counter-capacity. In the counter-capacity what was required was superficial area to take the electrical charge, and hence as light a substance as possible might be chosen.

The form of the future wireless outfit for airships would, Mr. Baker suggested, consist of a two-cylinder petrol engine coupled directly to an alternating current generator, the output of the latter being about two kilowatts, an aerial wire about 350 ft. in length, and a counter-capacity in the form of very thin metallic sheeting suitably disposed. Either a transformer for producing the high tension current and a zinc spark-gap or an arc transmitter would be employed.

Attention has been directed during the last few months to the production of portable apparatus. The chief limiting factor in small receivers is in connection with the detector. The vacuum valve detector of Professor J. A. Fleming will probably be the most suitable in many respects, and next to that an electrolytic detector.

QUESTIONS TO BE ANSWERED.

[The success which has attended our plan of publishing in each issue a list of questions covering the subjects considered in Jones' Diagrams, has encouraged us to maintain the work through other books. Students of telegraphy throughout the country are finding these questions of great assistance in their studies of the general principles underlying the operation of the apparatus with which they come in daily contact. Many consider this the best plan which has yet been devised for a systematic study of the technical side of the telegraph.. Having completely covered Mr. Jones' book we are now covering "The Quadruplex," by Maver and Davis, and will bring out, in a like manner, all the facts that every telegrapher should know about duplex and quadruplex telegraphy as found in this book.]

CHAPTER VIII (*Concluded*)

Does the insertion and removal of the various resistances from the line affect the total resistance of the quadruplex circuit?

What is the prime factor in obtaining the desired increase and decrease of current strength?

Why does a continuity preserving pole changer not work as well on a long line as on a short one?

Is the battery short circuited at any time when using the pole changer shown in Fig. 36?

In order to produce a difference of three to one in the strength of current which reaches the distant station what resistances should be used in the "added resistance" and the "leak?"

Is this margin sufficient for long circuits?

With a gravity battery how is the margin obtained?

In a battery of 300 cells, how many cells should be apportioned to the "short end?"

How is the margin in a quadruplex operated by machine currents varied?

In actual practice what are the values of the "added resistance" and "leak" resistance adopted to obtain a margin of four to one?

In the resistance box shown in Fig. 37 what is the effect of inserting plugs at L and R?

What means are provided to quickly open the circuits between the generating machines and the home instruments?

Referring to Fig. 38 what is the effect of turning the lever *B'* to the point *G*?

Why is the resistance of this connection made 600 ohms?

CHAPTER IX.

What are the essentials to secure successful operation of the quadruplex?

What is meant by intelligent handling of a quadruplex set?

How should the theory of the quadruplex be mastered and how should practical knowledge of its operation be obtained?

What is the "tap" or "tap wire"?

What is the effect on the current going to line of opening and closing the polechanger?

What is the "ground coil?"

What is the function of the ground coil?

What other name is sometimes applied to the ground coil?

What is the No. 1 relay?

What is the No. 2 relay?

What is the average internal resistance of a cell of battery?

What is the usual division of a battery on circuits of 100 miles in length?

By dividing in two portions what is the margin?

How is the margin widened on longer circuits, and what is the usual proportion of division on such circuits?

Why is it necessary to employ a wider battery margin on long lines than on short ones?

Two Kinds of Poles.—The manager of a telegraph office in examining applicants for positions as messengers asked one of the boys if he was not a Hebrew. The boy replied that he was not, but was a Pole. He was put to work, and the manager asked him later if he was a plain Pole. The boy replied that he was a plain Pole before he was hired, but since then he was a telegraph pole.

Copper Wire for South Africa.—Purchases will shortly be made by the Administration of Southern Rhodesia of copper telegraph wire for installation along the railway, the cost being estimated at $100,000. Considerable quantities of material will also be required for the installation of a metallic telephone system at Bulawayo in place of the existing single lines.

TELEGRAPH AND TELEPHONE AGE is the oldest and most ably-conducted telegraph journal in America and should be read by every one engaged in telegraphy. Subscription price, $2 per year.

Advertising the Telephone.*

BY JOHN LEE.

The most impressive sight we saw in America was a meeting of the New York Telephone Society. In a large theatre of the Engineers' Club in New York,—a beautiful building given by Mr. Andrew Carnegie at a cost of "a million and a half or so"—something like 1,500 men, mostly young, were assembled. An admirable paper on the commercial work of the telephone company was given by one of the commercial managers. It outlined the methods employed in canvassing and advertising. It revealed the intimate psychology of the process. It showed how the weaknesses of our common human nature were taken into consideration, how the world was convinced of the absolute necessity of a telephone in business enterprise and in domestic relationships. Not all of that fine audience were on the commercial side of the tripartite functions. Some were plant engineers, some were traffic engineers, some were local managers and agents. But the very excellent society sets out to give each member an insight into the work and ways of branches with which he is not directly concerned. It is a worthy ideal. It broadens the vision and enlarges the interest. Yet it does not connote for a moment that there is any misapprehension as to responsibility. The reader of the paper had no anxiety lest anyone should argue that the work which he described should be attached to another branch.

The psychology of advertising has received much attention in America. Lectures are given in at least one of the universities on the underlying philosophy of the advertising art. The idea is that the subconscious mind is what Locke said of the mind as a whole,—*a tabula rasa*. On this virgin wax many impressions are received and we know nothing of them. We are storing up in our mental furniture a host of ideas. They concern pills, shirts, boots, literature, watches, motor-cars, and typewriters. Day by day the advertiser strengthens the impression; he "rubs it in." The patient subconscious mind accepts it all, and when the moment comes for revelation, the impression springs, a vivid reality, into open consciouness. We have a pain—we think of certain pills at once. We have an uncomfortable shirt—the subconscious mind whispers to us of so-and-so's ever-comfortable shirts. We are athirst for information—the intolerability of life without the "Encyclopædia Britannica" is at once evident. Here, therefore, we find the first canon of advertising. It must hammer home one central idea on the subconscious mind. It must not look anxiously for direct results. It will get the results in due course, but that is a second process, and belongs to what the philosophers call the "collecting" period, a word which has philosophic kinship with our word "re-collecting." Its primary idea is to gather up in the stores department of the human mind certain information which will be available at the moment of need.

So the advertising of the telephone is divided into two distinct propaganda. There is the general propaganda: the telephone is useful to everyone. It saves time and money, temper and trouble. It is an ever ready servant. It is quicker than the post and more trustworthy than a messenger. It is preciously intimate, the binder of broken friendships and the solvent of civilized isolations. Day by day such asseverations are made. Their truth is unimpeachable. But bald general statements do not "drive home." They need to be focussed into something of direct interest, and the prevailing sentiment of the hour is used to catch the public eye. One of the best of these efforts was at the time of the recent explosion in New Jersey. The buildings in New York had been shaken to their foundations. There had been grave public anxiety; so the telephone company came out with an excellent advertisement in the newspaper: "Thousands rushed to the telephone. Husbands were anxious about their wives. Wives were anxious about their husbands. In a few moments the business of New York went on as before, for the anxiety was allayed. Have you a telephone in your home?" It was part of the general propaganda, but it had special point by reason of the fact that it chose as a peg the topic which was in everyone's mind. That is the sound philosophy of advertising.

But a calamity is not always at hand, so a calamity is not always necessary to the general propaganda. In the middle of last winter one of the companies issued a very pretty and effective newspaper advertisement. The picture showed a very beautiful lady sitting in a dainty boudoir, with pianoforte and literature and needlework—and yet she was obviously lonely. The letterpress explained it. "Books, needlework, music—these are all very well to alleviate loneliness, but a woman longs for the sound of a human voice. She longs to speak of the intimate things. And then the telephone bell rings—'Oh, Edith,' she says, 'I am so glad you rang me up, for George is away, and I was so lonely.'" I feel sure that such an advertisement awakened a responsive echo in many a gentle heart in Morningside and Montclair. At least the impression would arise in the conscious mind on the next occasion of loneliness, and that, of course, is the real aim.

Efforts are made, with very considerable success, to use the seasons of the year as a basis. For example, in the middle of the Christmas shopping season we are told that Santa Claus uses the telephone to very good purpose. Advertisements of that kind were used by the New York Telephone Company in both 1909 and 1910 respectively. When holiday season comes round a picture is given of the business man away at the seaside controlling his affairs in New York. Similarly, it is claimed that in the hot weather nothing is so successful as a telephone in grappling with the inconveniences of the heat, just as it was argued six months before that in cold and frost and snow the telephone was altogether indispensable. The small boy on July 4 is shown twining a telephone wire amid his fireworks. The lawyer is shown golfing; the physician is motor-

Digitized by Google

ing for pleasure; the political leader is a hundred miles from home, or a thousand, and all of them are kept in touch by the telephone. Singularly few of these advertisements deal with business proper in any form. This is left for the particularized method of circulars and personal canvass, and it almost resolves itself into a propaganda for the private branch exchange. The truth is that the day has long gone by when the utility of the telephone, in respect of business, needs any demonstration. It is rather the social side of life nowadays which calls for the public appeal. Hence it may be said that more than half the advertisements make their appeal to women rather than to men. It is not due solely to the fact that the United States is pre-eminently a woman's country, though this is beyond dispute. Rather it is that the next field to be conquered is that in which woman is specially triumphant.

Apart from general calamities there are particular emergencies in which the telephone is especially useful. With cunning art these are made the basis of alluring advertisements. One of them represents a business man who is invalided, conducting his business by telephone as he lies abed. To most of us this might be a positively repelling appeal, but the fact is that it is a particular utility which is highly esteemed by our cousins. The great railway king, Harriman, may almost be said to have died with the telephone in his hand. Another series of pictures deal with illness in the home. We see the boy, ill of scarlet fever, lying on his bed, with his mother in attendance. She is a prisoner, of course, but by her side is a telephone, and her smiling face as she uses it shows that it has had some influence in relieving *tedium vitae*. Other pictures of invalids show us the victims with wearied faces and usually dressed in elaborate dressing-gowns, but in all cases the telephone is their salvation. Burglaries form topics of a lurid type. The Philadelphia company issued one particularly thrilling picture. It represented a burglar, pistol in hand, mask on countenance, dark lantern by his side. With indignant scorn he is regarding a telephone. "It ruined my business," he is saying. Another picture on the same subject shows us the policeman arriving in the nick of time, while a third shows us comprehensively how every wild alarm meets its destruction in the telephone. Fire-engines are shown tearing along the roadway as a result of a telephone call, and houses, barns, and warehouses on fire form the frequent subject of illustration.

There is sound reason behind this clever advertising propaganda. To begin with, the telephone is the only article of commerce which is qualitatively of more value with the quantitative extension of its use. It is not of much value to me that 29,611 other people should get an "Encyclopædia Britannica," beyond the bare material fact that it enables me to get one cheaper. Nor do I care a straw whether the people in my suburb do or do not have the electric light, save that by an extension of users the price may be reduced. Nor am I anxious that the world should use the back-ache pills which give me such wonderful relief, or the bread-nuts or the cocoa which in time will build my muscle to the pitch of Hercules and my brain to the pitch of de Morgan. Hence (having myself succumbed), the advertisements for the "Britannica," or the backache pills, or the bread-nuts or the cocoa excite in me no feelings whatever. But I do want everyone else to have a telephone, since my own use is qualitatively more valuable with every new subscriber. Hence the advertisements lead me to the reflection that they are in my own interest. The more alluring they are the better the telephone subscriber likes them, and the more likely the non-subscriber is apt to like them. Moreover, it is possibly quite true that the alert mind which has led a man to be a telephone subscriber somewhat in advance of his fellows is evidenced also by his superiority in appearance. I do not think, therefore, that the American companies are exaggerating when they show that the telephone farmer is in advance of his non-telephone rival both in respect to the modernity of his braces and the comeliness of his wife. He is manifestly a thoughtful and enterprising man, and he has a wife (and braces) suited to his condition.

Should we advertise in England? In my opinion the answer is, Yes. I doubt if Englishmen want the death-bed telephone or the scarlet fever brand. At any rate I should not recommend advertising in that way. But I am sure that the psychology of advertising deserves careful study from the telephone point of view in order that it may be applied with due regard to English characteristics.

Effects of English Strike on Telegraph and Telephone.—During the recent strikes in England many railway and other telegraph and telephone lines were cut. The pressure on the telegraph service of the country was unprecedented. Great numbers of messages which would ordinarily have been sent by post were entrusted to the telegraphs. The operating staff, both in London and in the chief provincial centres, worked under severe pressure, but responded with the utmost readiness to the calls made upon them. The telephone service on the trunk system during the railway strike was phenomenally heavy. Calls poured into London from the seaside resorts and provincial centres from early morning to late evening, and the value of the telephone in such a national crisis was realized more than ever before.

New Insulating Material.—A new insulating material has been patented in England by W. J. Reid. Paraffin wax is treated with a mixture of from forty to sixty parts of finely powdered cork and from sixty to forty parts by weight of boiled linseed oil, for such a time that it becomes viscous and will draw into threads when becoming cool. This mass can be molded while hot into any desired shape.

Use of the Air for Wireless Telegraphy.*

The air is free to all, or, at any rate, it has been thought so until discussion upon wireless interference has become of importance. Now we have the knowledge that in England a license fee is charged, for the use of the air presumably, whenever a wireless station for transmitting is installed. Many bills on the same subject have been proposed in America, but up to the present time without result.

There is, moreover, some justice on the part of those who wish to limit the use of the air in this way. Since the loudness of signals depends upon the power of the transmitting instruments and the distance to be covered, it is possible for private persons and commercial companies to monopolize the space in certain vicinities, so that a most important government message cannot be received. It is, of course, to be understood that the government should have right of way, not only in the roads, but in the air.

Interference may be of two kinds, unintentional or malicious. In their effect there is no difference; but, as a matter of fact, it is the unintentional interference of experimenters unversed in the code, and without adequate breaking-in systems, that has given rise to most of the legislation hostile to them. Malicious interference either on the part of an experimenter or, as frequent complaints bear witness, on that of commercial stations, should be dealt with as severely as possible. It would seem that license restrictions would be too mild a treatment for such cases, and in all probability a method of dealing with them will be evolved.

In cases of unintentional interference, there is usually no remedy, as it is by an experimenter, or where the station is not properly equipped. No person should operate a transmitting set until he has a proper understanding of the codes, and, if he has no breaking-in system, without listening-in frequently to learn whether other stations are trying to make themselves heard. It is while a station is trying to receive messages from a distant source that interference is most objectionable. While a powerful station nearby is sending, a sending station of less power or different wave length may send without troublesome effect; but when it is trying to get signals from a weaker station, or one at some distance, the experimenter's interference will be most effective and most disastrous.

There are, however, some methods of overcoming interference. If the experimenter will use an oscillation transformer for sending, he will be able to tune his apparatus much more sharply. With a sharply tuned wave length, he will be received only by apparatus tuned in with his instruments most exactly. Therefore, if he is from fifty to one hundred meters either above or below the commercial station, he may be tuned out without trouble at the receiving instruments.

*From Wireless Operator's Pocket Book of Information and Diagrams, by L. W. Bishop

Another method of overcoming interference is by the new duplex system of wireless, where two aerials are used, one for sending and the other for receiving. The shorter aerial is for sending, thus ensuring a short wave length, much below that of the commercial stations. The longer aerial, for receiving, may be as large as is desired or needed, according to the distance to be covered.

Still another method is by the use of a breaking-in system, which will enable the experimenter to hear distant sending stations when they call, even while he is sending.

Where interference occurs with the government or commercial stations, a weeding-out or third (tertiary circuit) should be used. This will make the tuning of the receiving instruments twice as sharp as with the ordinary receiving loose-coupled transformer.

Operating and Testing Manual.

"Electrician's Operating and Testing Manual" is the title of an excellent book by H. C. Hortsman and V. H. Tousley, giving practical instructions for the management, operation and testing of the more important electrical devices now in use. It deals principally with electrical machinery and apparatus, and contains much information of general value to the student of telegraph and telephone engineering. A careful reading and study of the book will give one a comprehensive knowledge of electrical application in all branches outside of telegraphy and telephony. It is free from higher mathematics and the facts given are easily understood, the language used in explaining them is so clearly stated. Every telegrapher should familiarize himself with the various applications of electricity and this work will help him acquire that knowledge. The book is bound in flexible leather covers, and is sold at $1.50 per copy. Address TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York, for copies of this or any other book on electrical subjects.

Massachusetts Messenger Boy Law.—A recently enacted law in Massachusetts prohibits the employment of messenger boys under the age of 21 years after 10 o'clock at night. It is stated that in Worcester conditions are such that the telegraph companies do not feel warranted in employing men at the wages demanded to carry the few telegrams, or do the errands that may be offered after that hour. Telegrams received after that hour therefore may not be delivered until the next morning, unless the addressee can be reached by telephone.

A Little Mixed, but It Got There.—A telegram was received recently in a large city office addressed to the "Cattle Rangers' Cuttle Rye Co.," but before it was forwarded to its destination it was revised and sent to the "Cattaraugus Cutlery Co."

INDUSTRIAL NEWS.

Composite Telephone Set.

The composite telephone set shown in the accompanying illustration is in extensive use where additional wire mileage has been required, and yet the expense of stringing the additional wires themselves was not warranted. For such cases, the composite system possesses marked advantages in first cost, operating cost and maintenance. Its installation requires no additional line construction; its operation necessitates no increase in the operating staff, and

FIG. 1.—PORTABLE COMPOSITE TELEPHONE SET.

the absence of outside construction simplifies the maintenance problem. Signaling with a composite telephone, it is claimed, is infinitely more effectual than with the telegraph.

The signaling apparatus used with the set calls between stations by means of what is known as a howler. When one operator wishes to call another

FIG. 2.—COMPOSITE TELEPHONE SET.

he presses a button in the side of the telephone set. This action automatically starts an interrupter working, which sends out high frequency signaling current over the line and causes the howlers at the other stations to give the desired signal in a loud whistle or shriek.

No change in the telegraphic apparatus or its operation is necessary to adapt the system to telephone operation as well. Each telegraph station is merely bridged with a condenser and a resistance and the telephone apparatus is connected between the line and ground. A condenser in each telephone set prevents the telegraphic current from passing through this apparatus to ground.

It is said to be easily possible to talk on a composited line of this character while telegraph signals are passing over it, without any interference whatever. This apparatus is manufactured by the Western Electric Company.

Portable Testing Battery.

The portable testing batteries manufactured by E. Marcuson, of 136 Liberty Street, New York, although constructed on unconventional lines, have proved thoroughly practical, as is evidenced by the fact that during the past two and one-half years they have been adopted by such prominent corporations as the Postal Telegraph-Cable Company, the Interborough Rapid Transit Company, the New York Edison Company, the United Electric Light & Power Company, and many other electrical concerns.

Several small storage cells are assembled in boxes to form batteries of any desired voltage. At present, four standard sizes are carried, viz.: 100-volt, 140-volt, 168-volt and 256-volt batteries, their weights being 17½, 24½, 29 and 42 lbs., respectively. The illustration shows a man carrying a 100-volt and a 500-volt battery.

These batteries are used principally in insulation and capacity testing, calibration of instruments, potentiometer work, etc., but owing to the low internal resistance of the cells, their field of use is

PORTABLE TESTING BATTERY.

very wide compared with that of the usual type of testing battery. The battery is serviceable for testing the continuity of the wires and fittings of an installation before the main current is available by using an incandescent lamp for the indications.

As a further example of the flexibility of these batteries, it is pointed out by the manufacturer that on a recent occasion the line tester of a cable com-

Digitized by Google

pany was able, by means of his 100-volt battery, to actually maintain telegraphic communication during several hours, which result was, in this particular instance, of inestimable value.

A noteworthy feature of these batteries is that, although the various parts are visible, accessible and removable, they are of a portable nature.

Telephone Train Dispatching on the Nickle Plate.—The Nickle Plate Railroad has recently ordered of the Western Electric Company a complete telephone train dispatching equipment for its Buffalo division. This circuit will be 116 miles in length, and will extend from Buffalo, N. Y., to Conneaut, Ohio, where the train dispatcher will be located.

Telephone Train Dispatching on the Duluth & Iron Range Railroad.—The telephone system of train dispatching has been installed on the Duluth & Iron Range Railroad, between Two Harbors and Ely, with a branch from Allen Junction to Virginia and Eveleth, in Minnesota. The new system covers 123 miles and there are fifteen way stations. The equipment of telephones and selectors was manufactured by the Western Electric Company.

Electrical Code.—The Electrical Code of the City of New York for 1911 is a very comprehensive book of 212 pages and covers every electrical application. It comprises the rules and regulations for the construction, care, maintenance and operation of ducts, poles, conductors and other electrical appliances in the streets, public places and public and private buildings in New York City. The telegraph, telephone, wireless telegraph, etc., are thoroughly covered. The book is issued by the Department of Water Supply, Gas and Electricity, for which Professor George F. Sever is consulting electrical engineer, and copies may be obtained free of cost.

School of Telegraphy in Mexico.—A school of telegraphy will soon be opened in Mexico City, which will have for its aim not only the teaching of telegraphy, but also of electrical science, the construction of apparatus, and many other useful branches which will give the students a diversity of knowledge, so that they will not be confined to the telegraph operator's desk. A correspondence school will be maintained, so that students all over the Republic can have the benefit of this new institution. Ingeniero Carlos Islas Bustamante has been appointed superintendent of the school and he is securing competent professors in the various departments preparatory to opening the school at an early date.

Handy Electrical Dictionary.

This little book, of vest-pocket size, is a practical hand book of reference and contains definitions of electrical terms and phrases in use in every branch of electrical science. It is especially valuable for telegraphers and telephonists, and will be found a great aid in the understanding of electrical things and apparatus met with daily. It is thoroughly reliable, having been compiled by an engineer, and it will be found a very useful companion for students and others who wish to broaden their knowledge of electrical matters. It has a marginal index which is very helpful in rapidly finding the word or expression whose definition is desired.

The book is issued in two styles of binding, cloth and red morocco, the prices per copy being 25 and 50 cents, respectively. Address TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

Concrete Poles.

Mr. Frank C. Perkins contributes an article to the *Electrical Review and Western Electrician*, describing the construction of modern American concrete pole lines, from which the following extracts are taken.

A pole thirty feet in length will permit a deflection of thirty inches before the concrete cracks.

Even under tremendous strains the cracking of the cement, it is held, does not impair the strength of the pole in the least, for after this takes place the reinforcement becomes active and takes the entire strain; and as the special rods are guaranteed to withstand a breaking strain of 50,000 pounds per square inch, it is an easy matter to understand why this class of construction has two or three times the strength of cedar.

Rods are placed within three-quarters of an inch of the surface of the cement at the corners and then bound together by a spiral wire encircling the four rods from top to bottom. This not only serves to tie the rods together, but prevents danger of the cement shearing off, as the rods have a tendency outward when the pole is subjected to a lateral strain. Another important function performed by the spiral binding wire is that it ties the concrete together and increases the flexibility of the entire body.

The smaller poles, up to and including thirty-five feet in height, are molded lying on the ground, and after they have been seasoned are set in place by means of a gin pole. The forms are laid with the butt near the hole and the reinforcement placed. Then the concrete is poured in and allowed to remain three to seven days, according to the weather. The forms are then removed so that they can be used again and the pole is held to season. This process requires about three to four weeks, and the poles are then ready to be set and used.

Poles forty feet in length or larger should be built standing, as this is the most economical method. First the hole is dug, and then the form is set in place directly over it, lined up straight and perpendicular, and temporarily guyed so as to hold its position. The spiral binding wires are then put in place and the rods drawn up on the inside of the form and set. After the reinforcement has been properly secured, the side of the form that was left out to receive the steel work is put in place and the bands or ties around the outside secured. The equipment is then ready to receive the concrete pouring.

Atlantic City Reunion of Old Time Telegraphers' and Historical Association and Society of the United States Military Telegraph Corps, September 5, 6 and 7.

The thirtieth annual reunion of the Old Time Telegraphers' and Historical Association and the Society of the United States Military Telegraph Corps was held at Atlantic City, N. J., September 5, 6 and 7, under the most favorable conditions, and in point of attendance and enjoyment was the most successful meeting ever held by the two societies. The weather was delightful and the health-laden air, for which this famous seaside resort is noted, brought back to many of the old timers the enthusiasm and buoyancy of their younger days, and the Atlantic City reunion will long linger in their memories as one of the pleasantest events of their lives.

There was an attendance of 300, and a most enjoyable time was had by all. The meeting of old friends socially and the making of new ones afforded unbounded pleasure to all, and business cares were for the time being flung to the winds.

Nothing was left undone by the committees of arrangements and entertainment toward the enjoyment of the members and their families, and these committees deserve much praise for the able and successful manner in which they carried out their arduous duties. The visitors did not have any time hanging on their hands; there was an abundance of entertainment provided.

A pleasant feature of the reunion was the attendance of Mr. Edward Lynn Morse, of Stockbridge, Mass., son of S. F. B. Morse, inventor of the telegraph, and the old timers were particularly delighted at having an opportunity to meet an immediate member of the distinguished inventor's family.

Among other prominent telegraph men present were Mr. Stephen Dudley Field, also of Stockbridge, Mass., the well-known inventor and nephew of the late Cyrus W. Field; Messrs. David Homer Bates, C. A. Tinker and James Merrihew of New York. Another veteran was Mr. Daniel S. Robeson, an old-time line constructor. This was the first reunion that Mr. Robeson had attended. He met many of his old telegraph friends and seemed to enjoy every moment of the time spent with them.

The Society of the United States Military Telegraph Corps celebrated the fiftieth anniversary of the foundation of the corps by appropriate ceremonies.

The business meeting of the Old Time Telegraphers' and Historical Association was called to order promptly 10 o'clock a. m. on Tuesday, September 5, in Park Avenue Hall of the Marlborough-Blenheim Hotel, fully two hundred and fifty members being present.

Mr. David Homer Bates of New York, in appropriate remarks, installed the incoming president, Col. William Bender Wilson, of Holmesburg, Philadelphia, by pinning the Morse daguerrotype portrait on the coat of the new president.

President Wilson then introduced Mr. Alfred J. Royer, representative of the mayor of Atlantic City, who greeted the Old Time and Military Telegraphers and bade them welcome to the city by the sea. He also extended the freedom of the city to the members and their friends, and he expressed the hope that their stay would be a most enjoyable one.

Mr. M. J. O'Leary, of New York, responded to the welcome of the city in a very interesting address.

The reports of the secretary and treasurer, Mr. F. J. Scherrer, of New York, were then read, both of which showed a very satisfactory condition of the association's affairs. The treasurer reported a balance of $1,012.75 on hand.

Mr. J. H. Shearer, of Elmira, N. Y., made a motion to the effect that it would be to the best interest of the association to make every effort to increase the membership, and he thought each member ought to pledge himself to secure at least one new member during the coming year.

The Committee on Time and Place reported in favor of Jacksonville, Fla., as the place of the next meeting, the time to be the second week in October, 1912. The committee also recommended Honorable W. S. Jordan, an old time telegrapher and mayor of Jacksonville, as president; Paul R. Wiggs, of Jacksonville, Fla., a former telegrapher; H. C. Worthen, general superintendent, Western Union Telegraph Company, Atlanta, Ga., and George H. Usher, general superintendent, Postal Telegraph-Cable Company, Atlanta, Ga., vice-presidents, and Franklin J. Scherrer, secretary and treasurer; M. J. O'Leary and G. W. Logan of New York, auditors. The report was unanimously adopted.

Mr. E. P. Griffith of New York, chairman of the Turner Monument Fund, submitted the following:

"Your Committee, appointed to raise a fund for the erection of a monument with suitable inscription commemorative of the first railroad train order issued by telegraph, from the New York and Erie Railroad station at Turner (now named Harriman), N. Y., by Charles Minot, in 1851, then general superintendent of the New York and Erie Railroad, begs to report that a sufficient fund has been raised to provide a tablet under the plans agreed to by your committee, and that through the generosity of Mrs. E. H. Harriman, in kindly and cheerfully contributing the stone and expense for cutting the same, and also through the co-operation and generous aid of the Erie Railroad Company in providing a very suitable site for the monument, we are able to report that the dedication will take place late in October or early in November of the current year.

"While your committee has sufficient funds in hand to carry out the original plans, it has been wisely suggested that we elaborate on the tablet design and for that purpose further contributions are respectfully solicited.

"Your committee is greatly indebted to Mr. David Homer Bates for valuable suggestions and recom-

Digitized by Google

mends that he be made a member of this committee.

"It is the intention of the Association of Railway Telegraph Superintendents, who are jointly interested in this project, to send a large delegation to attend the dedication ceremonies, and it is recommended that the president of this Association confer with the president of the Association of Railway Telegraph Superintendents, and appoint a joint committee for that purpose, due notice of the date of the dedication to be sent to all members of such joint committee by the chairman of the standing committee."

The report was signed by the full committee and was unanimously adopted.

The convention then adjourned.

The Society of the United States Military Telegraph Corps met in business session at 8 p. m. Tuesday, Colonel William Bender Wilson presiding. After the completion of the roll call by Mr. David Homer Bates, of New York, secretary of the society, he read the names of the twenty-five members who had died during the previous twelve months.

The report of the secretary and treasurer was then accepted, and President Wilson delivered his annual address, which was listened to attentively.

Colonel William Bender Wilson was re-elected president of the society, W. L. Ives and Charles A. Tinker, of New York, first and second vice-presidents, respectively, and David Homer Bates of New York secretary and treasurer.

President Wilson appointed as members of the executive committee the following: Col. Robert C. Clowry, New York; William R. Plum, Lombard, Ill.; Col. Albert B. Chandler, New York; William J. Dealy, New York; Charles A. Tinker, Brooklyn, N. Y.; Richard O'Brien, Scranton, Pa.; John Wintrup, Philadelphia, and Marion H. Kerner, New York. An auditing committee, consisting of Charles A. Tinker, M. H. Kerner and W. J. Dealy of New York, was also appointed. The Committee on Congressional Action consists of A. A. Zion, of Indianapolis, Ind.; E. Von Eye, Crowley, La.; M. F. Robinson, Sanford, Fla.; Frank B. Knight, Dallas, Tex.; R. H. Bohle, St. Louis, Mo.; Ten Eyck Fonda, Omaha, Neb.; and J. J. Fowler, New Orleans, La.

Mr. C. A. Tinker of New York addressed the meeting at some length regarding the dedication of a monument to Edwin M. Stanton, at Steubenville, Ohio, and eulogized the war secretary in glowing terms.

The meeting then adjourned.

THE ENTERTAINMENT.

The official entertainment comprised six events, and each and all were highly enjoyed and appreciated.

On Tuesday there was a roller chair trip, starting from the Marlborough-Blenheim at 2 p. m. There were over 100 chairs in the procession. Mr. C. B. Wood was chairman in charge.

At 8.30 p. m. Tuesday the party attended an excellent concert and entertainment on the Steel Pier, and thoroughly enjoyed the fine music. Mr. Marion H. Kerner, of New York, was chairman of this function.

On Wednesday at 9 a. m. the party took trolley cars to the inlet, where they boarded sailboats and enjoyed a sail on the Atlantic Ocean. As no wireless equipment was provided, no one ventured out of sight of land. Mr. J. A. McNichol of Philadelphia was the skipper, and he managed the affair well.

At 2 o'clock Wednesday all hands were taken on a trolley ride to Ocean City. This was a most enjoyable trip in the fresh cool air. At 8 o'clock the members and their friends attended a concert and theatre entertainment on the Million-Dollar Pier. Mr. M. J. O'Leary of New York was the chairman of this event.

During the day on Thursday the members were free to do as they pleased, and fully two hundred and fifty of them spent most of the day in bathing in the Atlantic. At 6.30 p. m. the banquet was held at the Hotel Shelburne and an excellent menu was provided. Addresses followed the dinner and a thoroughly good time was enjoyed by all present.

The dinner was pleasantly interspersed by the singing of songs, beginning with the national anthem and ending with Auld Lang Syne.

The after-dinner addresses were as follows: "Morse and the Telegraph," by Colonel W. B. Wilson; Mr. Edward Lynn Morse spoke of his father's work and stated that he was at present engaged in the preparation of manuscript for a book which will contain his father's letters; "Carnegie and the Telegraph," by David Homer Bates; "Our Reunited Country," by J. E. Graybill; "The Telegraph in War," by W. L. Ives; "Comrades," by Richard O'Brien; "Fraternity," by M. J. O'Leary.

The ode to Morse, by Marion H. Kerner, was sung to the air "My Maryland."

NOTES OF THE CONVENTION.

When Colonel W. B. Wilson got up to open the banquet he found himself speechless, having left his speech in another coat in his room in an adjoining hotel. Being a man of resource, however, he soon "found" himself and the rest of his work was plain sailing.

Mr. J. J. Ghegan, president of J. H. Bunnell & Co., New York, distributed snapper sounders which were heard all over town during the three days of the convention. He also gave those present self-winding tape measures in celluloid cases. These were much appreciated by the fortunate recipients.

Mr. M. J. O'Leary, secretary of the Telegraphers' Mutual Benefit Association, made many friends for the worthy society he represented. He has the welfare of the association at heart, and his efforts should be enthusiastically supported.

Senator W. L. Ives is entitled to a high place in the "humorist" class. His speech at the banquet caused the greatest possible amusement, and everyone was convulsed with laughter. The funny part of it is the Senator does not realize that he is funny.

Among the forty-niners present were Nathaniel Hucker, of Buffalo; J. A. Sutherland of Englewood, N. J., and James Merrihew, of New York.

Mr. Charles A. Keck, of New York, the sculptor of the Turner Monument, was a guest at the ban-

Digitized by Google

quet and made many friends. He was plied with many questions regarding his work on the monument.

Mr. G. W. Deetz, of Atlantic City, a member of the executive committee of the Old Timers' Association, is entitled to the greatest of praise and commendation for his successful work in connection with the entertainment of the members. He was here, there and everywhere attending to the wishes of the visitors and ministering to their wants. The ladies and members of the various committees also deserve great credit for their efforts toward making the visit as enjoyable and comfortable as possible and their devotion to the cause won for them many friends.

Mr. Stephen D. Field went to Atlantic City to have a good time and become a boy once more, and he carried out his programme both in letter and spirit. His mind was as free from thoughts of quadruplexes and bug catchers as is that of a new-born babe.

A very handsome and artistic badge was worn by the members. On the upper section was represented a female figure in bathing costume reclining on the ocean beach, surrounded by various articles symbolic of the sea. A band across the face of the design bore the words "Atlantic City, 1911." The lower portion, which was pendent from a blue ribbon, consisted of a wreath surrounding a circular band in blue enamel, on which were the initials of the two associations—O. T. T. & H. A.—U. S. M. T. C. In the centre was the design of a telegraph key. The badge was made of heavy metal in imitation of oxidized silver and will be highly prized as a souvenir.

Among those present were the following:

Asbury Park, N. J.—C. R. Zacharias and wife.

Atlantic City, N. J.—Mayor Carmony, T. W. Wilson and wife, G. W. Deetz and wife, Judge Cole and wife, W. M. Phillips and wife.

Bridgeton, N. J.—Mr. and Mrs. Mulford, Sr.

Buffalo, N. Y.—N. Hucker, L. M. More and wife, Jos. Anderson.

Chicago, Ill.—John S. Henderson, Jack Magill and wife, F. M. Randolph and wife, Mrs. M. K. Holligan and Miss Kendrick.

Chattanooga, Tenn.—R. C. Jones and wife.

Claverack, N. Y.—James Merrihew, wife and niece.

Cleveland, O.—O. F. Stow, wife and son.

Detroit, Mich.—Roderick M. Ross and daughter, Richard H. Dunphy, James Moxam and wife, Alfred Lowther, wife, son and daughter.

Elmira, N. Y.—J. H. Shearer and wife.

Englewood, N. J.—J. A. Sutherland and wife.

Brooklyn, N. Y.—Thos. J. Cusack, wife, daughter and niece, Chas. A. Tinker, F. E. Coyle and wife, John B. Sabine and wife, V. J. Knittle and wife.

Freeport, Pa.—F. Kerney and wife.

Jersey City, N. J.—J. Flugauf and wife.

Jersey Shore, Pa.—H. W. Wedge.

Johnstown, Pa.—Peter Weitz and wife.

Monroe, N. Y.—J. B. Bertholf.

New York, N. Y.—F. E. McKiernan, Miss R. McKiernan, D. F. Mallen, Miss M. Mallen, J. M. Quill. D. H. Bates and wife, J. B. Taltavall, wife and son, Mrs. John Brant, Miss Josephine Allen, Henry Zweifel and wife, Miss P. C. Kuenstler, Miss M. Zweifel, Miss Eugenie Allen, H. W. Dealy and wife, Mrs. Marguerite C. Gates, John J. Ghegan, Edward L. Cohn, wife and daughter, Frank Kitton, Wm. Finn, A. M. Lewis and wife, R. J. Murphy, wife and daughter, F. D. Murphy and wife, J. F. McGuire, wife and son, L. Dresdner, Wm. Holmes, Wm. L. Ives, F. J. Sheridan, F. J. Scherrer, wife and daughter, M. H. Kerner and wife, M. J. O'Leary and wife, Mrs. Saml. F. Rice, W. B. Wood and wife, C. W. Parson and daughter, E. M. Mulford, Jr., wife and daughter, M. Green, wife, daughter and son, John A. Hill, A. Winder and Mrs. Fitzpatrick, J. H. Flood, P. A. Hickey and wife.

New Haven, Conn.—J. W. Ladd and wife.

Omaha, Neb.—Ten Eyck H. Fonda.

Pittsburgh, Pa.—J. A. Watson, J. W. Yealy, wife and daughter, F. J. McKenna and wife, D. Kelly and wife, W. K. Mellor and brother, W. I. McQuown, wife, daughter and sister-in-law, A. C. Terry and wife, Wm. Allenbaugh, wife, two daughters and son, T. E. Moreland, Virginia E. Moreland, Miss Jane L. Collins, Miss S. R. Haney, Miss L. J. Duncan, Miss M. H. Collins, John F. Amend, Jr., and sister, Mrs. F. J. Goersch, John Wentz, Charles R. Stough, W. R. Smith and wife.

Philadelphia, Pa.—John Wintrup and wife, Dan S. Robeson, E. L. Maize and wife, Andrew G. Wallace, Miss Jane S. Wallace, Miss Helen R. Sterrett, J. W. Crouse and wife, Sheldon Custer, John W. Benckert and wife, W. T. Westbrook, F. E. Maize and wife, E. H. Locke, M. Pease and wife, W. B. Wilson and wife, R. J. Meigs, A. S. Weir, W. W. Donnelly and wife, W. H. Butler, I. D. Maize, R. C. Murray, Jos. E. Janney and wife, J. M. Creamer, S. S. Garwood, J. W. Reed, R. C. Murray, W. E. Vanarsdall, Frank R. Webb and wife, Geo. Merrihew, L. L. Lutz, J. S. N. Phillips, A. G. Strickland, John H. Wilson, John Chattman, J. A. McNichol and wife, S. R. Crowder, C. B. Wood, C. E. Bagley.

Greensburg, Pa.—Miss Elizabeth Cogley.

Newburn, N. C.—Geo. Henderson.

Ottawa, Can.—G. F. Macdonald.

Passaic, N. J.—E. P. Griffith.

Paterson, N. J.—Chas. H. Snyder, wife and daughter.

Rochester, N. Y.—G. M. Case, wife and daughter, J. K. Parsons and wife.

Springdale, Pa.—Mrs. L. C. Adams.

St. Paul, Minn.—W. Weisel and wife.

Saginaw, Mich.—Wm. Henderson.

Stockbridge, Mass.—Stephen D. Field, Edward Lynn Morse.

Scranton, Pa.—Richard O'Brien and wife, Dr. J. E. O'Brien and wife, R. H. O'Brien and wife.

Digitized by Google

Trenton, N. J.—W. H. Wilmot and wife.
Vineland, N. J.—M. M. Prescott.
Washington, D. C.—Harry McKeldin and wife, Mrs. Wm. J. Bodell, W. S. Royer, wife and daughter, J. W. Collins, Mrs. H. F. Taff.
Wilkinsburg, Pa.—T. S. Fleming and wife, Miss Carrie Good, S. M. Geary and wife.
Winsted, Conn.—C. K. Hunt and wife.

THE NEW PRESIDENT.

William Spencer Jordan, the new president of the Old Time Telegraphers' and Historical Association, is a former telegrapher and is now mayor of Jacksonville, Fla. Mr. Jordan is a native of Florida, and has lived in that State all his life. He was born at Quincy, Fla., August 5, 1853, and began his telegraphic career at that place in October, 1869. From that time, until 1902, he served as railroad agent and operator at various places

HON. W. S. JORDAN,
of Jacksonville, Fla., President Old Time Telegraphers' and Historical Association.

in his native State, and, he says, "never missed a month's pay." In 1902 Mr. Jordan moved to Jacksonville where he has resided ever since. He is a man of force and commanding appearance and is very popular in that enterprising city. As its chief magistrate he is giving the city an administration that its best citizens are proud of.

Mr. Jordan is now engaged in the insurance business in Jacksonville, but, like the majority of old time telegraphers, he keeps in close touch with things telegraphic.

Morse and the Telegraph.

In his address on "Morse and the Telegraph," at the banquet of the Old Time Telegraphers' and Historical Association and Society of the United States Military Telegraph Corps, at Atlantic City, N. J., September 7, Col. W. B. Wilson, president, said:

"The effect on and the value to social advancement of that invention [the telegraph], which has penetrated and influenced all lines of human endeavor, is worthy the study of the sociologist. In its pursuit he will find that in the education of the hundreds of thousands of youth who have from time to time entered the telegraphic service, the most prominent and influential educational feature imposed by the invention is the one which compels concentration and rapidity of thought, correct interpretation, the inviolability of confidence and the cultivation of brevity in expression within the limits of clear understanding. The vast good to mankind of multitudes educated with such a feature as a firm foundation cannot be estimated. The invention brought into existence a new school for the training of scholars ambitious to excel in the ranks of those who battle for material progress and human uplift. That school is in reality a university with unlimited resources and the person who enters it, takes advantage of its opportunities and does not succeed in life must find the reason for failure in his own lack of ability or want of character. Out of it have gone not only those who have excelled in the science of electricity, but many others who have adorned or do now adorn the professions of law, medicine and theology, or have written their names high up on the tablets of art, commerce and agriculture, finance and manufactures, and statecraft and literature. They have won the world's respect and honor, yet with it all they have never forgotten their alma mater, but ever turn their eyes toward it, and from their hearts proceeds a constant stream of love and affection to the memory of its founder.

"In looking throughout this country and seeing the honorable positions occupied by men to whom the telegraph has been the foundation and medium of their education, who can truthfully say that the peaceful, useful family founded by Samuel Finley Breese Morse does not outweigh in importance the dynasties of emperors and kings?"

Marking Poles for Identification.—The New York Public Service Commission, second district, has ordered all public service corporations within its jurisdiction, maintaining poles or other structures for carrying overhead wires, to stencil or mark such poles with the initials of the owner and with a number whereby the location of any pole may be identified.

Stanton Statue Unveiled.—A statue of Hon. E. M. Stanton, Secretary of War during President Lincoln's administration, was unveiled at Steubenville, Ohio, September 7. At the ceremonies a paper by Mr. David Homer Bates, secretary of the Society of the United States Military Telegraph Corps, was read.

One of our agents in writing us states that: "It is surprising how many telegraphers spend more than two dollars and receive no benefit therefrom, while they hesitate and defer a payment of only two dollars for a subscription to TELEGRAPH AND TELEPHONE AGE that gives pleasure and profit for a whole year."

Annual Convention of International Association of Municipal Electricians.

The sixteenth annual convention of the International Association of Municipal Electricians was held at Young's Hotel, Atlantic City, N. J., September 12, 13, 14 and 15. The weather was delightful and there was a large attendance.

The first session was called to order by President H. C. Bundy of Watertown, N. Y., at 10 a. m. Tuesday, September 12, and an address of welcome was delivered by Hon. George W. Carmany, acting mayor,

Mr. J. B. Yeakle, superintendent of fire telegraph, Baltimore, Md., responded in behalf of the association.

A new engraved certificate of membership in the association, designed by Mr. Adam Bosch, superintendent fire telegraph, Newark, N. J., was shown.

After the appointment of an exhibit committee, adjournment was taken until 2 p. m. At the afternoon session, Mr. Warren E. Fastnacht, city electrician of York, Pa., read a paper entitled "Copper Clad Steel Wire in Overhead Fire and Police Service."

After an interesting discussion of the paper, President Bundy, in a few appropriate remarks, moved that Mr. J. B. Yeakle, of Baltimore, be made a life member of the association. The motion was carried and Mr. Yeakle in a feeling manner thanked the association for the honor.

A copy of a resolution passed by the American Institute of Electrical Engineers, and forwarded to President Taft, urging the formation of a commission to prevent patent abuses, was read. The matter was referred to a committee.

At the Wednesday morning session, several letters of regret were read from absent members.

Mr. J. W. Kelly, Jr., chief of electrical bureau, Camden, N. J., then read a paper entitled "Modern Police Signal and Flashlight Systems." He described the system in use in Camden as typical of modern up-to-date methods. He spoke of the need of the adoption of standard systems which could be enlarged as needed.

After a short discussion of Mr. Kelly's paper, Mr. W. E. Fastnacht of York, Pa., described the system of police telegraph to be installed in that city. The discussion which followed was participated in by Messrs. W. Y. Ellett, C. E. Diehl and McManus.

At the afternoon session an address in memory of the late Jervis Meyers and Stanley W. Manning, members of the Association, was delivered by Mr. J. B. Yeakle, of Baltimore. Mr. Yeakle's remarks were full of feeling. A committee, consisting of Messrs. Yeakle, Ellett and McManus, was appointed to draw up suitable resolutions on the death of Messrs. Manning and Meyers to be forwarded to their respective families and inscribed in the minutes of the Association.

The report of the committee on "Grounding of Fire and Police Patrol Boxes" was presented by Mr. T. C. O'Hearne, city electrician of Cambridge, Mass.

Mr. O'Hearne presented tabulated figures based on replies to a number of questions, bearing on different phases of the subject, which he had sent out. The majority of replies favor grounding. The committee recommended that the association go on record as favoring such grounding. It also recommended the appointment of a committee to consider and report at the next convention on methods to be used in grounding.

After some discussion on the report the meeting adjourned.

As the convention was still in session at the time of closing the forms for this issue, the remainder of the report will appear in our issue for October 1.

Among those present were:

Allentown, Pa.—P. J. Beisel.
Atlantic City, N. J.—Geo. P. Proffatt.
Altoona, Pa.—C. S. Downs.
Bayonne, N. J.—Wm. R. Arbuckle.
Baltimore, Md.—J. B. Yeakle, wife and daughter.
Buffalo, N. Y.—R. H. Potter.
Cambridge, Mass.—Timothy C. O'Hearne.
Camden, N. J.—John W. Kelly, Jr., M. Kelly.
Cincinnati, Ohio.—A. P. Crocker and wife, Wm. C. Kiehl.
Cleveland, Ohio.—H. A. Bowen.
Detroit, Mich.—Louis Gascoigne.
Elizabeth, N. J.—M. S. Van Houten and wife.
Elmira, N. Y.—Will Y. Ellett.
Houston, Tex.—Clarence R. George.
Indianapolis, Ind.—John Berry and wife, O. C. Turshi.
Louisville, Ky.—Chas. F. Gall, P. G. Kern.
Little Rock, Ark.—John W. Bleidt and wife.
Meadville, Pa.—A. J. Balizet.
Mobile, Ala.—C. S. McCosker.
New York, N. Y.—Wm. D. Ligon, Mrs. John Brant, Fredk. Pearce and wife, Mrs. W. H. Pearce, E. Marcuson, T. Torrey and wife, H. M. Voorhes, John M. Spader, E. H. Fondersmith, R. A. Paterson, V. G. Stanley and wife, Allen D. Cross, Richard C. Smith, V. L. Crawford, A. P. Eckert and wife, Egbert C. Chamberlin, C. C. Johnson, Geo. P. Fondersmith.
New Rochelle, N. Y.—A. J. Bell and wife.
New Haven, Conn.—A. L. W. Kittredge, Miss F. G. Kittredge.
New Brunswick, N. J.—Robert Stuart.
Newark, N. J.—Adam Bosch and wife.
Norfolk, Va.—R. A. Smith.
Ottawa, Can.—Geo. F. Macdonald.
Pittsburgh, Pa.—Mrs. C. B. Sill, C. W. Abbott.
Philadelphia, Pa.—Chas. S. Redding, Julius Bernstein, N. B. Hazeltine.
Peoria, Ill.—W. E. Wolgamott.
San Antonio, Tex.—W. A. White.
Springfield, Ohio—T. S. Bosley.
Toronto, Ont.—John P. Craig and wife.
Watertown, N. Y.—H. C. Bundy and wife.
Wilkes-Barre, Pa.—R. H. McManus.
York, Pa.—Warren E. Fastnacht.

KERITE

INSULATED WIRES and CABLES

DEPENDABLE

Kerite Cables installed upward of 35 years ago, and exposed to deteriorating influences, are giving perfect service to-day.

EFFICIENT

Kerite does not rely upon the rubber in its composition for insulating efficiency. Kerite itself is a compound having superior insulating qualities.

SERVICE

A half century of successful service has demonstrated that Kerite possesses the essential qualities of safety, reliability and economy to an exceptional degree.

Kerite Insulated Wire and Cable Co.

The Railroad.

Mr. S. L. Van Akin, Jr., assistant superintendent of telegraph of the New York Central and Hudson River Railroad, Syracuse, N. Y., has charge of the railroad forces and telephone construction and maintenance.

Mr. E. E. Backus has severed his connection with the United States Electric Company, New York, to accept the position of superintendent of telegraph of the El Paso and South Western Railway, with headquarters at El Paso, Tex., vice H. W. Cutshall, resigned.

Mr. Charles Selden, superintendent of telegraph, Baltimore and Ohio Railroad, Baltimore, Md., whose appointment as general inspector of transportation in addition to his duties as superintendent, was announced in our issue of September 1, will be chairman of the committee on operating rules of the Baltimore and Ohio system. He will inspect train dispatching on the road, examine the work of dispatchers on all divisions and have general supervision of the transportation movement of trains. At the recent annual convention of the American Train Dispatchers' Association in Baltimore Mr. Selden was elected an honorary member.

Mr. Frank S. Spafard, acting superintendent of telegraph of the Chicago, Rock Island and Pacific Railway, Chicago, was born in Manchester, Mich., January 31, 1853, and began his telegraphic career at Osage, Iowa, in September, 1869, on the Illinois Central Railroad. He remained with that road until 1882, filling various positions in the meantime. From 1882 until 1892 he was train despatcher for the Burlington, Cedar Rapids and Northern Railway and superintendent of telegraph for the same road from 1892 until 1902. In the latter year he was appointed assistant superintendent of telegraph of the Chicago, Rock Island and Pacific Railway, and still retains this title, while performing the duties of superintendent of telegraph in place of the late J. G. Jennings.

Hours-of-Service Law in Texas.—The United States District Court at Austin, Tex., has fined the St. Louis Southwestern Railway Company $1,000 for violations of the telegraphers' clause of the Federal hours-of-service law. An appeal will be taken.

Railroads May Send Money by Telegraph for Transportation.—The Interstate Commerce Commission has issued an order allowing railroads to send money by telegraph to buy tickets. This is for the benefit of those who wish to send transportation and traveling expenses to people at a distance by paying the fare at the railroad office in the place where the sender lives.

Telephone Train Dispatching on the Grand Trunk.—Mr. W. W. Ashald, superintendent of telegraph of the Grand Trunk Railway System, Montreal, Que., states that the two telephone train dispatching circuits which have been in operation on his lines for the past eighteen months are giving excellent satisfaction and that it is the intention to use the telephone over the entire system. He does not think, however, that any additional circuits will be installed during the current year.

The Late J. G. Jennings.

The funeral of the late J. G. Jennings, superintendent of telegraph of the Chicago, Rock Island and Pacific Railway Company, Chicago, whose death was recorded in our issue of September 1, was held August 22, and was largely attended by prominent telegraph and railroad officials. Among the telegraph representatives present were Messrs. T. P. Cook, general superintendent; M. T. Cook, division commercial superintendent; W. J. Lloyd, division traffic superintendent, and A. B. Cowan and J. Fitzpatrick, district commercial superintendents, Chicago; J. G. Hilbert, district plant superintendent, Dallas, Tex., and others.

The railroads were represented by Messrs. W. M. Whitenton, general manager Rock Island lines, Fort Worth, Tex.; George H. Crosby, vice-president, and F. O. Melcher, second vice-president, Rock Island lines, Chicago, and many other general officials, and the following superintendents of telegraph: G. A. Cellar, Pennsylvania Lines West of Pittsburgh, Pittsburgh, Pa.; E. A. Chenery, Missouri Pacific, St. Louis, Mo.; P. W. Drew, Milwaukee, St. Paul and Sault Ste. Marie, Chicago; V. T. Kissinger, Chicago, Burlington and Quincy, Chicago; W. W. Ryder, general superintendent of telegraph, New York Central Lines, Chicago; F. S. Spafard, assistant superintendent of telegraph, Rock Island Lines, Chicago; F. T. Wilbur, Illinois Central, Chicago, and F. H. Van Etten, Southern Indiana, Chicago.

Radio-Telegraphy.

Mr. Jack R. Irwin, the wireless operator of the Wellman airship, was married recently to Miss Helen MacPage at Portland, Ore. Mr. Irwin is a native of Australia and is well known in telegraph and wireless telegraph circles.

Wireless on Motor Launches.—Many small motor launches are now equipped with wireless telegraph apparatus.

Wireless Station at Fort Sam Houston.—A powerful wireless telegraph station is to be established at Fort Sam Houston, Tex., by the Army Signal Corps, under the direction of Major George O. Squier.

Wireless in Peruvian Navy.—The Peruvian cruisers *Almirante Grau* and *Coronel Bolognesi* are the only ships of the Peruvian navy provided with wireless equipment, but it is expected that two other ships will be fitted out with wireless apparatus. The range of action of the two existing ship plants is 250 miles during the day time and from 250 to 1,500 miles at night. The wave length employed is about 900 feet.

Digitized by Google

Wireless in the Amazon Country.—The Amazon Wireless Telegraph and Telephone Company of New York, is ready to accept business between Para, Santerem and Manaos, Brazil. It is 700 miles from Para to Manaos, which is in the centre of the rubber region.

Wireless on a Sailing Ship.—The cadet ship *Mersey* of the White Star Line is said to be the first sailing ship equipped with wireless telegraphy. The *Mersey* recently arrived in the River Thames, England, and the wireless apparatus on board was worked for eleven months without a single breakdown, notwithstanding the fact that none of the men on board had had any practical experience with wireless telegraphy. The Marconi system is used.

Wireless Station at Danzig.—The wireless station opened at Danzig, Germany, May 15, for general communication with ships at sea works from 6 a. m. till midnight in connection with the ordinary telegraph service. The T-shaped antenna rises to a height of 150 feet. The power is provided by 220-volt continuous current from the Danzig Municipal Works. The energy in the antennæ is 2.5 kilowatts. Both senders and transmitters are provided with variable wave-length scales. The normal range is nearly 400 miles by day and twice that distance by night, but the station has interchanged messages over a distance of 1,370 statute miles.

Intercepting Wireless Messages.—The demurrer interposed by Mr. Edwin T. Earl, a publisher of Los Angeles, Cal., to the indictment charging him with having published the contents of an intercepted aerogram, was sustained by Judge Bordwell, of the superior court. An appeal from the ruling will be taken. Judge Bordwell held that the law of 1872, to safeguard the contents of telegraphic messages, upon which the indictment was based, applied only to officers and employes of telegraph companies, and that, therefore, Mr. Earl committed no offense when he published an aerogram taken out of the air by three amateur wireless operators.

Wireless Messages from Automobiles.—A number of cadets from a military academy of the Northwest, says the *Electrical Review and Western Electrician*, are now making a tour of about three thousand miles through the east and back to Chicago in four automobiles, whose engines drive the generators for the electricity of the wireless apparatus with which each machine is equipped and the machines are operated about thirty or forty miles apart, communication being maintained by means of the wireless.

Each machine is provided with an extension mast, while balloons, also forming part of the equipment of each machine, can be utilized for carrying the antennæ to any desired height. The expedition expects to visit Washington, New York and other places.

A Brave Young Wireless Operator.—During the recent hurricane off the Carolina coast the steamer "Lexington," bound from Savannah to Philadelphia, was driven ashore on Edisto Island, and her wireless station wrecked. Jack Sheetz, the wireless operator, climbed the rigging at the risk of his life, and by means of improvised equipment sent out the distress signal, "S. O. S." The call for help was received by the revenue cutter "Yamacraw," which went to the aid of the disabled steamer. Sheetz, it is stated, is only sixteen years of age, and when the rescuing vessel arrived he climbed down from his perilous station in the rigging and fell exhausted on the deck.

Traveling Wireless Inspectors.—The Marconi International Marine Communication Co., Ltd., announces that it has appointed thirteen traveling inspectors, whose duties are: (a) to take charge of installations on ships; (b) to observe the working of ship and shore stations, and, whenever necessary, to report to head office instances of inattention or bad working; (c) to visit the company's ship stations in foreign ports, inspect installations, verify maintenance certificates, and render to operators any assistance that may be required; (d) to install apparatus on ships when required. Each inspector will have a letter or card of identification, which he will present, in order that the operator in charge of a station may give the necessary facilities for inspecting and overhauling the apparatus.

Pedersen Rapid Wireless System.—Many experiments have recently been made in the rapid transmission of wireless messages by the Pedersen system, says the London *Electrical Engineer*. The first attempts were made between Esberg and Lyngby, in Denmark (167 miles), then between Lyngby and Cullercoats (560 miles,) and finally between Lyngby and Knockroe, in Carlow, Ireland (900 miles). Speeds of 300 words per minute have been attained. The transmitting station works with a Poulsen generator, so that it acts by undamped vibrations. For signalling the primary circuit is not used, but only a small part of the self-induction in the antennæ is short-circuited. Half of one per cent. out in the tuning is good enough to enable clear signals to be given by the receiver, which is fitted with a crystal detector and a string galvanometer. The signals are marked on a tape automatically.

Story of Stanton During the Civil War.—Mr. David Homer Bates, secretary of the Society of the United States Military Telegraph Corps, New York, is the author of an interesting article in this week's *Leslie's Weekly*, entitled "Stanton in the Dark Days of the Civil War." It is a very readable story and gives one an excellent picture of the famous War Secretary.

Mr. Harry Morlan, manager of the Postal Telegraph-Cable Company at Salt Lake City, writes: "I wish to congratulate you on the success you have achieved in making TELEGRAPH AND TELEPHONE AGE one of the headliners of them all, in the telegraph and telephone field. Success to you always."

New Main Switchboard in New York Operating Room, Postal Telegraph-Cable Company.

BY DONALD McNICOL, OF THE ELECTRICAL ENGINEER'S DEPARTMENT, POSTAL TELEGRAPH-CABLE COMPANY, NEW YORK.

Several years ago the engineering department of the Postal Telegraph-Cable Company, realizing the importance of those problems which involve efficient and satisfactory switching systems, undertook the development of a central office switchboard which would embody those essential features, typical of the great advances made in contemporaneous lines of engineering work.

In developing a new type of switchboard the aim was to provide against fire hazards, to develop a unit system, which may be added to at any time without interruption to or disarrangement of units already installed and in service, to provide for compactness and flexibility, and to employ materials best suited to the various purposes.

Formerly, the construction of telegraph switchboards was carried on without due recognition of the fact that although telegraph wires ordinarily do not carry electric currents of such volume that there is a fire risk; the possibility of exposed lines coming in contact with other wires carrying dangerous potentials necessitates switchboard construction similar to that required for high tension wires.

Before the reconstruction of the switching system of the New York main office was undertaken, the new features intended to be embodied therein,

FIG. 1—SECTION OF NEW SWITCHBOARD, POSTAL TELEGRAPH-CABLE COMPANY, NEW YORK.

above referred to, were tried out in less important offices throughout the country, so that when the larger undertaking was launched each new departure had been thoroughly tested and perfected. How well the department planned in advance of the times is strongly evidenced in the flexibility of the new switchboard. Although this board was designed and its construction commenced several years ago, its rapid switching possibilities have been found to meet all new demands imposed by changing traffic conditions.

The construction and wiring of this board, two views of which are shown in the accompanying illustrations, was done without interruption to the service. The various units were installed separately.

All of the materials used were chosen only after careful investigation. The iron framework, the slate panels upon which the terminal connections, switches, etc., are mounted, the insulation material, the meter equipment, the pin jack and spring jack equipment were all selected with the object of anticipating future development as far in advance as good engineering could suggest.

Immediately in the rear of the switchboard proper are situated the terminal frames and cross-connecting frames constructed of iron and with plenty of aisle space between adjacent sections. From the terminal frames all connections are made with the main boards, leg boards, city boards, etc., by means of overhead cables. The attaching and suspending of these cables has been accomplished in a manner so workmanlike that while thousands of connections were needed to make up the circuits, there

FIG. 2—LOOP BOARD.

are no loose wires in view and the appearance of the terminal room as compared with switchboard building of a decade ago, clearly indicates the great advances that have been made in interior telegraph construction.

The two views shown give a general idea of the imposing and substantial appearance of this new board. The sections shown are those containing the west and south lines. Other sections of the board, not shown, contain the north and east lines.

The annunciator board shown in one of the photographs is an efficient auxiliary to reliable leased wire service. By means of this system the lessee has an instantaneous means of calling the attention of the main office to any interruptions or lapses of service. The annunciator attendant at the main office, who in each case is an expert wire chief, is enabled to cut in on any loop without leaving his chair.

One excellent feature of the new board is the system of "transfers," that is, the method of intercommunication between the various sections of the board. The attendants in charge of each section are able to transfer circuits to any remote section of the board by means of pin jack connections immediately in front of them, and without having to use rows of discs or long cords as formerly.

A high telephone official states that TELEGRAPH AND TELEPHONE AGE is by far the most valuable paper for information and general telegraph and telephone news that reaches telephone people.

Repeater Adjustments.

BY GEORGE F. MILLIKEN, BOSTON, MASS.

In reading the article on repeater adjustments, by Mr. C. L. Higgins, of Cheyenne, Wyo., contained in your issue of September 1, I am led to call attention to the special means employed in the Milliken repeater to obviate the trouble noticed by Mr. Higgins in all of the repeaters mentioned in his communication.

This special feature consists of an independent spring for the extra local magnet, having the necessary tension to hold the relay armature mechanically closed while its main circuit is open; or more properly speaking, until the closing of the main circuit has effected the closing of the relay armature.

The extra local battery should be of sufficient strength, and the poles of the magnet near enough to the armature, to insure an effective holding of the relay armature lever under any possible high relay adjustment.

Turning up the armature spring of the extra local magnet causes the armature lever to lag in releasing the relay amature lever, after the closing of the main circuit. This action may be compared with the lag of any relay armature on a high tension adjustment when operated by the home key. In the case of this repeater, the home key is the sounder lever, and the adjustment of the extra magnet spring should be turned up until the lag slightly exceeds, or overlaps the lag of the relay lever which it is holding and which may be necessarily adjusted high on account of line escape.

Telephonography.

Prof. Pierluigi Perotti has been conducting experiments on the Italian state telephone lines with a new apparatus designed to record telephonic speech on phonograph cylinders.

The sending station contains the usual type of telephone transformer, to the primary of which a high sensitivity granule-microphone is connected in series with a four-cell (three point) primary battery.

The secondary of the transformer is connected to the metallic circuit line, and, at the receiving station, the incoming lines are connected to two loud speaking receivers in series. One of the receivers is used in the ordinary manner, but the second receiver communicates with the recording membrane of a Pathé phonograph, which is coupled to the sound box by a rubber sleeve.

The membranes are thus connected by a small enclosed volume of air. The vibrations of one membrane are transmitted to and repeated by the other, and are thence recorded by a sapphire style on a wax cylinder. The tube is attached to the traversing carriage of the phonograph, the receiver and sound box moving as one piece, this being permitted by the use of slack flexible leads.

It is advisable to speak somewhat louder than usual into the transmitting microphone and to provide a rather higher battery voltage in the sending circuit than is usual in telephone practice.

It is not compulsory to use the recorders, but the simple turning of a locking screw enables any or all of a message to be recorded at will. The record obtained can be subsequently reproduced at any time or place, and an imperfectly heard message can be repeated as often as desired, thus avoiding delay and all risk of error.

All the trials so far carried out show the present apparatus to be sensitive and accurate; applicable to any telephone line; cheap in first and operating costs and quite satisfactory in the hands of ordinary subscribers.

The Turner Monument Fund.

On September 2, Mr. E. P. Griffith, chairman of the Turner Monument Fund, Mr. R. S. Parsons, superintendent New York Division of the Erie Railroad, Mr. Charles Keck, of New York, sculptor of the monument, and Mr. C. T. Ford, superintendent of the Harriman estate, met at Harriman, N. Y., formerly named Turner, and selected a very appropriate site for the monument. Mr. Ford has begun work on the stone and Mr. Keck states that the bronze work will be finished by November 1.

The honor of unveling the statue has been offered to Miss Gertrude M. Griffith, daughter of Mr. E. P. Griffith, chairman of the Monument Fund, who has given so much thought and time to the enterprise and brought it to a successful issue. It is a fitting recognition and expression of appreciation of his work that his daughter should be selected to perform this pleasant duty.

There are no doubt many persons throughout the country who would like to become identified with the movement. These yet have an opportunity to send in their subscriptions to the treasurer of the fund, Mr. J. B. Taltavall, 253 Broadway, New York. All subscriptions are acknowledged in the columns of TELEGRAPH AND TELEPHONE AGE.

Contributions received up to date are as follows: Previously acknowledged, $1,653.25; Telegraphers' Mutual Benefit Association, New York, $1.00; Interest to July 1, 1911, $12.24; F. G. Sherman, New York, $5.00; F. M. Randolph, Chicago, Ill., $1.00. Total, $1,672.49.

The Awakening of China.—The cutting and stealing of the telegraph wires seems to be an everyday occurrence in Manchuria, the South Manchuria Railway Company having experienced no fewer than eighty-eight cases of the kind during the last three months.

Our Subscription Contest.

The announcement in our issue of September 1 of the opening of a contest for prizes to be awarded to those of our agents who send in the greatest number of subscriptions from September 1 until December 21, is beginning to show results and each agent is urged to do his utmost to se-

Digitized by Google

cure the first prize, which will be $50. There will be five prizes in all, the second being $25, the third $15 and the fourth and fifth $5 each.

The conditions of the contest were published on page 594 in the September 1 issue and all interested in this matter would do well to study them carefully.

The contest is not limited to present agents alone. Anyone in a section where we have no agent can take up the work of canvassing by securing an agency appointment. Agents in a country district will find as great a field for obtaining subscriptions as does the city agent in his locality. All the operators are not in the cities, and it is those outside of the large offices that we particularly desire to reach.

This contest presents an excellent chance for hustlers to earn some extra money easily. There is only one first prize and all the contestants stand the same chance of capturing it.

Annual Meeting of T. M. B. A.—The annual meeting of the Telegraphers' Mutual Benefit Association will be held at 195 Broadway, New York, November 15. In accordance with a resolution passed at the last annual meeting the proposition to amend section 2 of article IV of the constitution will be acted upon. The section amended as proposed will read as follows: "Sec. 2. There shall be an Executive Committee consisting of six members who shall be elected as hereinafter described. In addition the officers and those who have heretofore been presidents of the association shall be ex-officio members of said committee."

LETTERS FROM OUR AGENTS.

NEW YORK, WESTERN UNION.

Under the supervision of Mr. W. A. McAllester of the Central Cable office, an opportunity has been given to the messenger boys, the office boys and the clerks to learn telegraphy by attending an electrical class two nights a week. This educational feature is being gone into very thoroughly and the young men are much pleased at the outlook for their future. They recognize that there is promotion ahead for them and the initial meeting found fifteen of them eager to learn the telegraph profession. Mr. C. H. Burkner a well posted member of the staff is acting as teacher.

NEW YORK, POSTAL.

Mr. J. J. Whalen, manager of this office, recently returned from a five weeks' trip on company business. He visited various western cities, including Chicago and St. Louis, and Toronto and Montreal, Canada.

PHILADELPHIA, POSTAL.

Mr. P. A. Hickey, chief operator of the Cotton Exchange, New York, and wife, were recent visitors.

Night chief operator E. H. Locke has returned from his vacation.

Manager J. A. McNichol and cashier J. H. Wilson represented this office at the recent Old Timers' Convention at Atlantic City.

The great telegraphic song hit,
"SEND ME A NIGHT LETTER, DEARIE."
Good, catchy music; beautiful title design magnificently printed in colors. Title contains night letter. Sung all over New York, 17c. by mail. All popular music sent by mail.
B. L. BRANNAN,
195 B'way, N. Y.

Mecograph.—The operator of today has a great many advantages over the operator of a decade or more ago. He can do his work with much less fatigue by the use of a sending machine, and he is free from the danger of becoming a victim of telegrapher's cramp. The Mecograph Premier is a sending machine that is well known and widely used. It is of simplified design and possesses many points of value that should be considered well by all intending purchasers. It is constructed in a first class manner and can be permanently adjusted. See the company's announcement on another page of this issue.

Among sound and reliable insurance organizations the Telegraphers' Mutual Benefit Association of 195 Broadway, New York, occupies a foremost place. Organized in 1867, it has paid to beneficiaries of deceased members $1,500,000. Reserve Fund, $327,000, the largest Reserve in proportion to liabilities that is held by any similar Association. All persons engaged in Telegraph or Telephone service between the ages of 18 and 45 are eligible for membership, no restrictions after admission as to change of occupation or residence. The lowest possible cost consistent with security offered. Write for blanks and further information.

TRANSMITTING MACHINES

I am placing on the market improved YETMAN TRANSMITTING TYPEWRITERS, and KEYBOARD TRANSMITTERS without typewriting features. Am prepared to exchange, repair or rebuild all old machines. Write for catalogues and particulars to

James Uncles, NORTH ADAMS Massachusetts

Rubber Telegraph Key Knobs.

No operator who has had to use a hard key knob continuously should fail to possess one of these flexible rubber key caps, which fits snugly over the hard rubber key knob, forming an air cushion. They render the touch smooth and the manipulation of the key much easier. Price, fifteen cents.

J. B. Taltavall, TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

Every one engaged in telegraphy and telephony should be a constant reader of TELEGRAPH AND TELEPHONE AGE. It gives the latest news in both these fields. Subscribe now. Subscription price, $2.00 per year.

SOME POINTS ON ELECTRICITY.

BY WILLIS H. JONES.

Some Radical Alterations in Telegraph Apparatus.

It has been intimated by outsiders who evidently are not aware of all that is transpiring in the telegraph field that telegraph engineering has not advanced as rapidly in proportion as many other industries of like importance.

The fact is, however, that progress has not only kept well in step with other engineering developments in the past, but there are indications that the pace set will soon be so great that the critics may have to do a considerable amount of hustling to keep up.

During the past few years many changes in apparatus and methods for the betterment of the service have been made, and more are ready for installation. The principal reason many of the contemplated alterations have not been put in practical operation before has been due to the uncertainty of the outcome of the merging of the telephone and the telegraph interests from an economical and business point of view.

Now that this question has been finally settled the new office which is now being erected in New York, will contain much that is entirely new and revolutionary in the way of telegraph equipment.

In addition to the adoption of the more efficient Athearn quadruplex system, already in practical operation, many radical changes are to be made in the switchboards and office paraphernalia.

Probably the most noteworthy as well as important alterations contemplated will be the substitution in some boards of telephone jacks, somewhat modified, for the old wedge system, the minimization of cords, and an improved "office loop" arrangement.

In order to appreciate the superiority of the telephone jack method over the wedge system it is only necessary to give a description of the construction of the new loopswitch to be installed and note the contemplated alterations in the office loops, or legs.

The accompanying diagram will give the reader a good idea of the proposed changes. Instead of a springjack all multiplex local terminals at the loopswitch will consist of telephone jacks

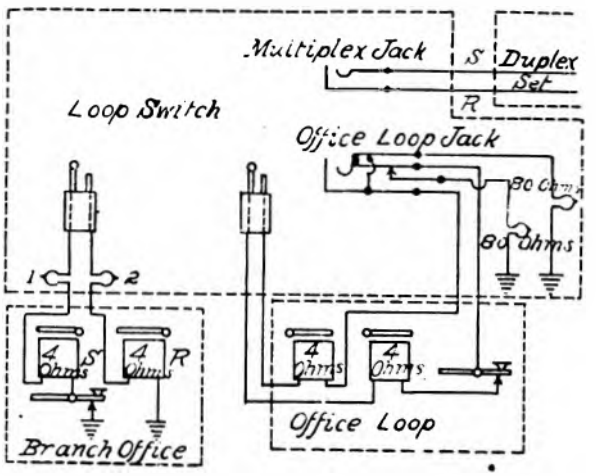

DIAGRAM OF TELEPHONE-JACK SWITCHBOARD.

similar to that shown in the upper right-hand corner of the illustration, while the wedges which now represent the terminals of the branch office loops, repeaters, special batteries, quadruplexes, etc., will be replaced by the usual telephone plugs as shown in connection with the office and branch loops.

The jack for the office loop is specially constructed, having four tongues instead of two, the purpose of which will be explained later. This office loop requires only one cord; the old style requires two.

Before further description, attention is called to a few weak points in the old system which the new method is expected to remedy. In the first place a wedge is reversible, hence the receiving and sending sides of a duplex loop may accidentally be transposed during rush hours and cause unnecessary delay. With a telephone jack such a thing cannot happen.

Again the spring, in time, weakens and wedges

Digitized by Google

sometimes fall out unnoticed from the weight of the cords, while the hinge pin often becomes rusted and makes a poor connection. These faults, and they are frequent in old switchboards, will be entirely eliminated in the new apparatus.

NEW OFFICE LOOP ARRANGEMENT.

One of the greatest improvements to be made in the new equipment is that in the office loop. In the old or present type the compensating lamp resistance which is cut in when a branch loop is removed from the multiplex set is located on the desk where the operator works and is controlled by him or the traffic chief by a double three point switch, also on the desk. The weak point of this method is that whenever a branch loop is to be cut in or removed from the circuit the traffic chief must first be notified. As the legs are usually some distance from the quadruplex department, which gives the orders to connect or disconnect the loops, and in some cases in another room, considerable delay often occurs before the notice is received. In addition to this operators sometimes turn the switches the wrong way and this causes further delay before the trouble is discovered. By means of the new method shown in the accompanying diagram such delays cannot occur as the switching will be done automatically, the three point switch being eliminated and the lamp removed from the desk.

Furthermore, when telephone jacks are used the sending and the receiving sides of a loop cannot be reversed as is now possible when the wedge forms the terminals. Still another advantage derived from the new arrangement is that only one cord is required against two in the old style.

It will be seen that the new office loop jack is somewhat differently constructed from the regular telephone jack, as it possesses four tongues or conductors instead of two, the extra pair being connected to the two compensating lamp resistances, which will be located behind the loop switchboard. For illustration, if the office loop alone is to be placed on a multiplex set the loop simply inserts the plug in the multiplex jack in the usual way. By tracing the course of the current it will be seen that after flowing through the office loop sounders it reaches the ground through the lamp resistances shown. When a broker or branch office loop is added to the circuit the plug for the latter is placed in the office loop jack, also shown in the diagram. The insertion of this plug lifts levers leading to the grounded lamps and the current then shifts its course through the loop conductors where it finds a ground at the branch office. The removal of the loop restores the ground behind the board, hence no one is required to be notified to complete the operation.

In case two office loops and one grounded branch loop are to be connected with the multiplex set the first office loop plug must be removed from the multiplex jack and placed in the jack of the second office loop, while the plug of the latter in turn must then be placed in the multiplex set jack. To add the branch office loop it is then only necessary to insert the plug of that loop in the jack of the second office loop.

1,002,239 and 1,002,240. Telephone System. To A. H. Dyson, Chicago, Ill.

1,002,267. Morse Transmitter. To T. Habermann, Hemslingen, Germany.

1,002,277. Telephone System. To A. R. Kahl, Rochester, N. Y.

1,002,563. Sender for Automatic Telephone Systems. To E. E. Clement, Washington, D. C.

1,002,713. Selective Signaling System. To O. M. Leich, Chicago, Ill.

1,002,735. Automatic Telegraph-Key Closer. To D. E. Motz and F. B. Hatfield, La Jara, Col.

1,002,783. Detachable Telephone Support. To B. W. Sweet, Cleveland, Ohio.

ISSUED SEPTEMBER 12.

1,002,832. Sound-Conducting Attachment for Telephone Receivers. To C. H. Gatchell, Boston, Mass.

1,002,878. Party-Line Telephone System. To S. A. Souther, Chicago, Ill.

1,002,891. Telephone System. To C. S. Winston, Chicago, Ill.

1,002,936. Telephone Attachment. To R. E. Southwick, Los Angeles, Cal.

Personal.

Mr. C. D. Lee, president of the United Press, New York, is on a business trip through the middle west.

Mr. S. S. Garwood of Philadelphia was in New York September 20, attending an executive committee meeting of the Telegraphers' Mutual Benefit Association, of which he is a member.

Mr. Dion J. Arnold, of Chicago, a prominent electrical and mechanical engineer and an old-time telegrapher, has been retained by the city of San Francisco, Cal., to investigate the street railway situation there.

Mr. E. K. Dyer of the Western Electric Company, San Francisco, Cal., son of Mr. I. T. Dyer, superintendent of telegraph of the San Pedro, Los Angeles and Salt Lake City Railroad Company, Los Angeles, Cal., was a recent New York visitor.

Mr. John H. Bell, engineer with the Western Electric Company, New York, whose appointment was recorded in the September 1 issue, has had a valuable technical experience in the British service. He was born at Aberdeenshire, Scotland.

Digitized by Google

September 6, 1879, and entered the telegraph service as operator in the Central Telegraph office, London, in 1895, where he remained until 1900. He was operator and engineer in South Africa during the Boer war, between 1900 and 1902, and between 1902 and 1911 he was on the staff of the engineer-in-chief of the British post office. During the present summer he came to New York and accepted a position with the Western Electric Company.

Mr. A. L. W. Kittridge, superintendent of police telegraph, New Haven, Conn., was a recent New York visitor.

Mr. Gilbert F. Hayes, wire chief, Western Union Telegraph Company, at Cheyenne, Wyo., was married to Miss Frances D. Ries on September 6.

Mr. G. H. Groce, assistant to the president of the General Railway Signal Company, Rochester, N. Y., was a recent New York visitor.

Mr. F. G. Creed, manufacturer of the Creed automatic printing telegraph system, London, England, is in the United States on business connected with printing telegraphy.

Mr. F. G. Jones, of the Jacksonville, Fla., Western Union office, who has been in the hospital at Philadelphia for several weeks, has returned to Jacksonville in excellent health.

Postal Telegraph-Cable Company.

EXECUTIVE OFFICES.

Mr. Clarence H. Mackay, president, has returned from a few weeks' visit to Europe.

Mr. C. C. Adams, second vice-president, New York, is on his way home from Europe and will arrive on the steamer "Kronprinz Wilhelm" about October 3.

Mr. George G. Ward, vice-president and general manager of the Commercial Cable Company, New York, arrived from Europe on the steamer *Adriatic* September 28.

Mr. W. I. Capen, general superintendent of plant, New York, will leave for Jacksonville, Fla., October 1.

Misses T. N. Brown and E. M. Allen, and Mrs. A. W. Porter of the executive department have returned from a trip through the West, which they made together.

Mr. J. H. Hess, of the electrical engineers office, New York, has resigned to accept the position of manager of the Monticello Telephone Company, Monticello, N. Y. Mr. Hess has been in the service of the construction and engineering departments of the Postal Company for the past twelve years.

Mr. W. H. Romedy, of the Jacksonville, Fla., office, has been appointed chief operator at the same point, vice W. J. Johnston resigned. Mr. Romedy holds the remarkable bonus record of 885 messages in nine hours.

Mr. Joseph Johnson, chief operator of the Western Union Telegraph Company at Houston, Tex., has resigned to become chief operator for the Mackay Telegraph and Cable Company at the same place.

The Mackay Telegraph and Cable Company has opened offices at Houston and Galveston, Tex. It will open an office at Austin, Tex., on October 10 and at San Antonio at the end of the month.

Postal Telephone Service.—The Postal Telegraph-Cable Company announces telephone service over its wires between San Francisco, Sacramento, Reno and Salt Lake City. The rate between Salt Lake City and San Francisco is $1.50 for the first five minutes. Between Sacramento and San Francisco the rate is 25 cents for the first five minutes, each additional minute being charged at the rate of 5 cents.

Magnetic Club Fall Dinner.

The Fall dinner of the Magnetic Club, New York, will be held on the evening of Wednesday, November 15, probably at the St. Denis Hotel. The club will entertain as guests the delegates to the annual meeting of the Telegraphers' Mutual Benefit Association, which will be held in New York the same day.

A Royal Wireless Operator.—King Albert of Belgium has had a complete radio-telegraphic system installed at his palace at Laeken for the purpose of conducting experiments.

Western Union Telegraph Company.

EXECUTIVE OFFICES.

The annual meeting of the stockholders of this company will be held October 11, and the election of officers for the company will take place a week later, October 18.

Mr. H. C. Worthen, general superintendent, Southern Division, Atlanta, Ga., was a recent executive office visitor.

Mr. W. J. Bagby, district superintendent of the American District Telegraph Company of New Jersey, with headquarters at Philadelphia, was a recent New York business visitor.

Mr. H. E. Johnson of Cortland, N. Y., has been promoted to the managership of the Niagara Falls, N. Y., office, vice C. H. Simpson advanced to be manager of the Brooklyn, N. Y., office.

Mr. T. J. Farrell, formerly manager of the Bridgeport, Conn., office now occupies a position in the office of Mr. W. A. Sawyer, district commercial superintendent, New York, in connection with telephone matters. Mr. Farrell was succeeded by Mr. G. C. Wardwell, formerly of Mr. Sawyer's office.

The following managers have been appointed in the Southern Division: Mr. Herbert Hall, at Beaufort, S. C., vice E. A. Donaghue; Mr. C. J. McNab, at Barnwell, S. C., vice H. Mullis; Mr. D. M. Dunn, at Pulaski, Va., vice Miss A. V. Nealon, transferred to special duty at Oxford Orphan Asylum; Mr.

Digitized by Google

T. C. Parker, at Suffolk, Va., vice Rogers White, who leaves the service; Mrs. H. L. Hall, at Wadesboro, N. C., vice Mrs. M. R. Thompson, and Mr. J. E. Hill, at Dillon, S. C., vice C. E. Peck, who enters other business.

Mr. O. Stanley, manager at Vicksburg, Miss., has been transferred to Memphis, Tenn., as manager of the Cotton Exchange branch. He is succeeded by Mr. L. C. Flora, formerly manager of Corinth, Miss.

Mr. W. M. Burt has been appointed manager at Corinth, Miss., vice Mr. L. C. Flora, transferred to Vicksburg.

Mr. C. Savage has been appointed manager at Laurel, Miss., vice Mr. J. A. Pryor, resigned, and Mr. E. F. Ramey, at Owensboro, Ky., vice Mr. J. W. Porter resigned. Mr. H. H. Ramey has been appointed manager at Paintsville, Ky.

Mr. P. F. Dowd has been appointed manager of the office at 129 Columbus Avenue, New York, vice H. Putterman transferred to the operating department at 195 Broadway.

Mr. George S. Walters, district commercial manager at Pittsburgh, Pa., has been transferred to a like position at Clarksburg, W. Va. He will have charge of the northern West Virginia territory.

Mr. W. O. Walters, manager at Uniontown, Pa., has been transferred to the managership at Jamestown, N. Y., vice J. C. McGrew.

Mr. L. A. Watson, manager of the East Liberty branch office, Pittsburgh, Pa., has been advanced to the managership of the Uniontown, Pa., office, vice W. O. Walters.

Mrs. Josephine Rawson has been appointed manager of the East Liberty, Pittsburgh, Pa., office, vice L. A. Watson.

Mr. L. L. Leith, formerly Morse wire chief of the Central District and Printing Telegraph Company, Pittsburgh, Pa., has been appointed special agent of this company at the same point. He will have charge of joint telephone-telegraph matters, leases and renovations.

Mr. Earl Burton, formerly in charge of the messenger service at the Pittsburgh office, has been appointed district supervisor of messenger service for the entire district.

Mr. Joseph Diehl, formerly delivery clerk, has been appointed supervisor of messenger service for the city of Pittsburgh.

Mr. Edmund J. Burke, assistant manager of the Springfield, Mass., office, has been appointed manager of the Burlington, Vt., office, vice Mr. C. B. Kelley transferred to Springfield as manager.

Mr. F. M. Houser, chief operator at Jacksonville, Fla., has resigned to enter other business. On his retirement he was presented with a gold watch from his office associates, Mr. H. O. Turner acting as spokesman.

Mr. W. L. Glasheen, who was transferred from San Francisco, Cal., to the plant department of this company at New York, has returned to San Francisco for the same interests.

A game of baseball played on September 23 between the teams representing the supply department and the general manager's office was won by the former, the score being 15 to 3. The victorious team is under the management of Mr. H. J. Schaper.

A club and rest room and a place for instruction is being arranged for the employes of this company at Minneapolis, Minn.

The Telephone.

New Exchange for Lowell.—The New England Telephone and Telegraph Company will erect a new exchange building in Lowell, Mass.

Telephones in New York City.—The number of telephones installed in New York City September 25 was 426,244, an increase of 24,718 since January 1.

New Exchanges for New York Telephone Company.—The New York Telephone Company will enlarge its exchange at East Orange, N. J., and will build an extension to its Watertown, N. Y., exchange.

Chinese Telephone Directory.—The Illinois Tunnel Company, Chicago, which is installing an automatic telephone system, has so large a business among the Chinese residents of that city that it has gotten out a directory printed in Chinese characters.

Obituary.

Thomas E. Crimmins, a well-known contractor, who installed most of the electrical subways in New York, died September 8.

William Wickenson, aged 70 years, who was chief electrician of the steamship "Great Eastern" when she laid the first Atlantic cable, died at his home in Revere, Mass., September 13.

Nicholas Lee, formerly chief operator of the Western Union Telegraph Company at St. Paul, Minn., died August 17 of heart failure. At the time of his death he was connected with the plant department of the same company at Minneapolis. He was a well-known and highly respected official of the company.

Thomas M. King, aged 66 years, an old time telegrapher and a member of the United States Military Telegraph Corps during the Civil War, died at his home at Irvington-on-the-Hudson, N. Y., September 14. Mr. King retired from active business many years ago. He was prominent as a railroad official for twenty-five years, being for a greater part of that time vice-president of the Baltimore and Ohio Railroad. He attended the Chicago reunion of the Old Time Telegraphers' and Historical Association in September, 1910.

Wireless in Portugal.—The Portuguese government has notified the British and Italian governments that it has decided to adopt the Marconi system of wireless telegraphy. Stations are to be erected at Lisbon and the principal ports along the coast and at Cape de Verde.

Convention of International Association of Municipal Electricians, Atlantic City, N. J., September 12, 13 and 14.

In our issue for September 16 we printed the proceedings of the first two days of the convention of the International Association of Municipal Electricians at Young's Hotel, Atlantic City, N. J., September 12, 13 and 14. The convention being still in session at the time of going to press, we were compelled to withhold the rest of the report for the present issue.

At the morning session of Thursday, September 14, Mr. H. M. Beck, of the Chicago office of the Electric Storage Battery Company, Philadelphia, read a paper entitled "The Storage Battery in Municipal Service." The paper dealt largely with the care of storage batteries and the author pointed out the importance of giving them proper attention in order to obtain the best working results from them. The paper was fully discussed by the members and many facts of interest were

J. W. KELLY, JR.,
Camden, N. J., President International Association of Municipal Electricians.

developed. Extracts from the paper are published on another page of this issue.

At the afternoon session Mr. A. C. Farrand, formerly city electrician of Atlantic City, read a paper on underground construction, in which he pointed out the relative values of rubber and paper insulation for cables. The paper was very fully discussed.

The election of officers for the ensuing year resulted as follows: President, J. W. Kelly, Jr., Camden, N. J.; first vice-president, John Craig, Toronto, Ont.; secretary, Clarence R. George, Houston, Tex.; treasurer, C. E. Diehl, Harrisburg, Pa.

The executive committee consists of W. E. Volgastt, Peoria, Ill.; A. C. Farrand, Atlantic City, N. J.; A. L. Pierce, Wallingford, Conn.; R. A. Smith, Norfolk, Va.; John Berry, Indianapolis, Ind.; W. R. Arbuckle, Bayonne, N. J.; C. S. Mcosker, Mobile, Ala., and Louis Gascoigne, Detroit, Mich.

The convention then adjourned to meet in Peoria, Ill., in September, 1912.

THE EXHIBITS.

There was an extensive display of apparatus of all kinds of interest to municipal electricians.

Mr. E. Marcuson, of New York, exhibited portable testing batteries and a portable lighting outfit for use in manholes, etc.

The Duplex Metals Company, of Chester, Pa., was represented by Messrs. G. P. and E. M. Fondersmith and R. A. Paterson. They showed copper-clad, bare and insulated wire and cable and copper-clad nails.

The Gamewell Fire Alarm Telegraph Company, of New York, had an extensive exhibit of its apparatus. It showed an improved flashlight for summoning patrolmen; also fire alarms for schools and factories. The exhibit also included a storage battery equipment for operating fire alarm systems. It was in charge of Mr. T. Torrey, general agent.

ENTERTAINMENT.

There was an abundance of entertainment provided for the members and their friends. On Tuesday evening the ladies of the party were given a roller chair ride on the boardwalk. On Wednesday evening a "gabfest and electrical stunts," were given in the convention hall.

The programme further provided a trolley ride to Longport and return to Inlet Park, Thursday afternoon, which was followed by a complimentary dinner to the association by the Gamewell Fire Alarm Telegraph Company.

Saturday morning a trip was made to Camden, N. J., also a visit to the New York Ship Yard and inspection of the great battleships there, followed by an automobile ride.

Our Subscription Contest.

It is desired that every agent of TELEGRAPH AND TELEPHONE AGE shall take active part in the contest for the prizes offered in our issue for September 1, for the largest number of new subscriptions during the months of September, October and November, and up to December 20, when the contest will close. The subscriptions are now beginning to come in, and the results so far are satisfactory, but it is evident that all of our agents have hardly got into full operation. Every one of them should put on an extra pressure of energy. There is a large field to work in and their success in obtaining new subscribers depends upon their own efforts. The first prize is $50, and the possibility of winning this is certainly worth a little extra effort on their part. Everyone has an equal chance in winning one of the five prizes.

In offices where there is no regular agent an agency may be established by securing an appointment, and any reliable person can thus enter the contest. An agent in a small office has just as good a chance to win as has the one in a large office, and we hope that many more new agencies will be established. There are many telegraphers throughout the country who are not subscribers, but who ought to be for their own good. If these are approached in the proper manner they can be won over.

Joint Telegraph and Telephone Offices.

The following announcement is made by Mr. S. M. Williams, of the Western Union Telegraph Company, New York, with reference to the joint use of offices by the Western Union Telegraph Company and the American Telephone and Telegraph Company:

Supplementary relations between telegraph and telephone services are being carried into further practical operation in the Eastern Division of the Western Union Telegraph Company. Joint use of facilities during the past year has been confined principally to wires. Now a system of joint offices is being put into effect, for the increased efficiency of the service and the greater accommodation of the public.

In very many of the smaller communities, the only telegraph office is in the railroad station, under control of the railroad agent, and usually it is located at some distance from the business center of town. It is open for business, as a rule, only during day hours. On the other hand, the telephone office and exchange is centrally located and open for business day and night.

There are many very small communities that have no telegraph office at all, but are reached by the telephone. These will now have a Western Union office.

In working out a plan to meet the varying conditions it was found advisable to divide the joint offices into four classes, designated as Class 1, Class 2, Class 3, and Class A.

Class 1 is an office turned over by the telegraph company to the telephone company for the latter to operate telegraphically as agent of the former. The telegraph company runs its wires to the telephone office and furnishes the necessary equipment. Offices of this class will be in the larger towns and villages where there is sufficient volume of business to require the services of a telegraph operator. The telegrapher will be an employe of the telephone company, but performing both telegraph and telephone duties. Separately, there would not be enough duty to occupy the time of an employe, but the joint service permits economical operation of the office. So far as the telegraph part is concerned, the routine of the office, the keeping of records and the making of reports will be the same as at regular telegraph offices.

Class 2 offices are identical with those of Class 1, save that they are not operated telegraphically, but by telephone; that is, the business being of too small volume to warrant the services of a telegraph operator and telegraph installation, it will be transmitted by telephone to the nearest independent Western Union office. At Class 2 points, telephone subscribers will be connected directly to the Western Union office, to which the business is transferred, but anyone desiring to personally file a message may do so, in which case the employes of the telephone company will transmit the same to the transfer telegraph office.

On the other hand, business destined to Class 2 offices will be telephoned by the transfer telegraph office to the telephone subscriber. If the addressee has no telephone, the transfer telegraph office will telephone the message to the telephone operator for delivery from the Class 2 office. There will be no additional telephone toll charges for customers at Class 2 offices. The standard telegraph rates will apply.

Class 3 offices will include such stations and toll stations as may be agreed upon at points where the telephone company does not operate an exchange and where at the present time an additional toll line charge is exacted. It is proposed, so far as the telephone company can control such points, to make them Western Union offices and eliminate the toll line charge. The method of operating these offices by telephone is identical with those in Class 2.

The Class "A" offices will include those now known as "Public Pay Stations" in cities and towns where the telephone company's attendants will accept and forward telegrams to the local telegraph office, the attendant acting as agent for the telegraph company. No telephone toll charge is to be made to the person desiring to send telegrams at such stations.

In the Eastern Division up to September 15, sixty-two offices of Class 1 type are being operated by the Associated Bell Companies or are in process of installation. Most of these are in New England, but the New York Telephone Company is inaugurating the same policy in its territory.

A large number of Class 2 and Class 3 offices have been, or soon will be, taken over by the Associated Bell Companies. Of the Class A type, there have been 983 offices already established.

The public will appreciate this combined service because it will afford continuous telegraph service at practically all Class 1 and Class 2 points, where formerly there was a limited hour service.

In addition, there will be abolished the extra charges on telegrams that have heretofore been imposed on many small communities not reached by the direct telegraph lines.

Secret Telegraph.—Mr. Walter P. Phillips, a well known old time telegrapher and formerly general manager of the United Press and the United Associated Presses is the inventor of a secret telegraph system which was designed to avoid the eavesdropping evil on telegraph wires. To accomplish this a telephone receiver is placed in parallel with the sounder or relay and one stop or contact of that instrument is made silent by substituting a stop of rubber or other suitable material, thus mutilating the signals. A switch is provided for cutting the telephone receiver out when not in use. When a station is called the operator can recognize his call, even though the signals are mutilated. He then throws his switch, cuts in the telephone receiver, cuts out the sounder and receives the message.

Telephones in England and the United States.*

BY T. F. PURVES, OF LONDON, ENGLAND.

So far as telephones at least are concerned we in this country [England] have always freely admitted the immense contributions to the development of the art which have come to us from across the Atlantic. America was the cradle of the telephone and has been from the first peculiarly its home. Its telephone engineers have led the world. The multiple switchboard, which first enabled large numbers of lines to be handled in one exchange, the common battery lamp signalling system, which greatly improved the service and reduced its working costs, and the automatic or machine systems of telephony, which aim at the elimination of the human agency of the operator, are all the product of American brains, and many of the original and most notable pioneers of these developments are still in active and responsible control.

So we have no kind of diffidence in seeking information from the Americans or in copying anything in their practice that will suit the conditions of this country.

But I would not give all the credit for the wonderful development which has scattered eight millions of telephones up and down the United States to their engineers and commercial managers. The American public has taken to the telephone as a duck takes to water, and its insistent demand has been a continuous spur to those in whose hands the provision of the service has rested. Its progress has been greatly helped by the absence of many of the facilities for cheap and rapid postal and telegraph communication, to which we on this side are so accustomed that we have ceased to notice them. The post is uncertain, and in country districts people have sometimes to travel a long way to post or obtain their letters. It is slow compared with ours, especially for internal city communications. The telegraph has been costly and poorly developed. Even at the present day there is a vast rural community which it does not serve at all.

I think the tendency to the erection of tremendously high buildings in American cities has also helped the telephone. When a man's office is perched, it may be, on the twentieth or thirtieth floor, he wants to do as much business as possible without going outside, and the telephone is a *sine qua non*.

I think the telephone is better suited to American business methods than to English. The American makes important contracts by word of mouth and is quite contented to do much of his business by telephone. He has recognized it as the greatest time-saver ever invented, and as a business-bringer that he cannot afford to be without either in his office or his private house. Consequently he sees that he gets it, and he doesn't mind paying for it. When the same attitude becomes general on this side of the water we are not likely to hear so much of England's backwardness in telephone development.

The telephone companies of the United States are, at the present time, divided into two great camps—the "Bell" companies and the "Independent" companies. The former group represents the companies formed to work the system under the patents of Prof. Alexander Graham Bell, the acknowledged father of telephony. There are between thirty and forty such local Bell companies covering the whole of the country, and they are now gathered into an aggregate of partially autonomous units under the general guidance and control of the American Telephone and Telegraph Company, which also owns and works in its own name a huge network of long-distance lines connecting up the various local companies and providing them with inter-communication up to the extreme distance limits of telephonic speech. Its total capitalization is, I think, somewhere around $700,000,000, and its president, Mr. Theo. N. Vail, is one of the financial powers in the land.

The number of "Independent" companies runs into hundreds. Some of them are large and comparable with the Bell companies, but for the most part they are quite small. The operations of the small companies are, in many cases, confined to a single town. They came into existence as the result of local enterprise, on the expiration of the Bell patents several years ago, with the idea of cheapening the service by competition. Taken altogether they now own about half the total of 8,000,000 telephones. The spirit of competition between the Bell companies and the independent companies is very keen. It has banded the independents into a fairly coherent group, which strives with might and main, and with a vast amount of sound and fury, to get the better of its formidable rival. Many of the advertisements and counter-advertisements are distinctly amusing, and the battle is followed with much relish and appreciation by the general public.

I am afraid I must admit that the telephone service is distinctly smarter in the large towns of America than it is with us. We have plant and equipment practically identical with that of New York or Chicago, yet the result in speed of service does not seem to be as good. So far as I have had chances of observing in the States, all classes of workers—builders, porters, street excavators, meat packers in Chicago, iron and steel workers in Carnegie's Pittsburgh mills, factory hands of all kinds, waiters, clerks, telegraphists, and, I fear I must add, telephone operators—seemed to apply themselves to their business more diligently and whole-heartedly and with more effortless efficiency than we are accustomed to see on this side. Yet in America telephone operators are much more difficult to get than in this country, and might therefore be expected to adopt more easy-going and independent ways.

The long-distance service in America is often referred to as much more prompt than that given by the British Post Office, but the general statistics of the two services as a whole show that the average delay before a trunk connection can be obtained in England is not very much greater than it is in America. The superiority of the American service is principally in communication between large centres,

*From The Post Office Electrical Engineers' Journal, London.

Digitized by Google

and in this respect it is indisputable. The explanation is simply that trunk lines between the principal cities are provided in America on a much more lavish scale than has been done in this country. Consequently the American rates are high; as a matter of fact they are two or three times as high as the British Post Office charges for conversations covering the same mileage. This is a very important point which should not be lost sight of when comparing the two systems. The public pays with the usual American readiness, but nevertheless the statistics show that the trunk service is relatively much less used than it is in this country—another very important point in comparisons of public utility. The small man cannot afford the luxury of as much long-distance telephoning as he can here, and the richer users, who can afford it, get the benefit in promptitude of service. In this country, with its lower charges, the trunk lines carry far more traffic, and one has to wait longer for one's turn. It would be a hard matter to get the British public to stand the increase in the trunk charges necessary to pay for the building of the great numbers of additional lines which would be required to bring the service up to the American standard. Each line must bring in an adequate revenue to pay for working and maintaining it if the service is to be conducted on a business footing, and the problem the Post Office has to face in the speeding up of the trunk service is not at all an easy one. I may say that not only do our trunk lines show a much smaller proportion of idle time than those in America, but the proportion of waste time, that is, time occupied in passing calls and arranging for connections, is also much lower.

On the point of quality of speech transmission there is not much to choose between the two administrations; if anything, I think, the balance is in our favor. Our lines are, on the average, more carefully constructed.

How to Increase the Membership of the Old Timers.

BY J. H. SHEARER, ELMIRA, N. Y.

At the Atlantic City convention of the Old Timers, September 5, 6 and 7, I suggested the necessity of increasing the membership of the association and the advisability of each member pledging himself to secure at least one new member during the coming year. I realize that it is easy to suggest things, but quite a different matter to carry them into execution. Lest I be placed in this category, I desire to point out a way to increase the membership of the association which I think should be very effective.

Let each member send to the secretary the names of all old operators whom he may know, and the secretary can then take the matter up directly with the prospects, sending printed literature and other pertinent information. No member should, however, let his efforts drop then. He should use his best endeavors to get the eligibles interested and thus supplement the work of the secretary.

A little personal persuasion will accomplish a great deal in this work, and every member who knows of eligibles should take the matter up in earnest.

QUESTIONS TO BE ANSWERED.

[One of the most effective means of imparting information is to ask and answer questions, the value and power of this method being due to the fact that the information given in an answer is specific and direct. Asking questions for the student to answer for himself has proved to be an excellent means of education, as it promotes and encourages concentration of thought and investigation in order to arrive at the correct answer. There is a general demand for knowledge on the quadruplex, duplex, etc., and to aid in the acquirement of such knowledge we are extending our aid to students by asking questions on these subjects in each issue of our journal, so that students may be encouraged to study by answering them. We use as our text book Maver and Davis' "The Quadruplex," and students should have a copy of this book at hand in order to be able to give the answers. The questions are progressive and a careful reading of the book on the points under inquiry unfold the answers. This method of acquiring technical knowledge is a fascinating one.]

CHAPTER IX (*continued*).

What is meant by the balancing of a quadruplex?

How is a quadruplex balanced?

What is the ground coil?

What is the purpose of the ground coil?

Should the resistance in the ground coil be varied?

What is the effect of altering the ground coil resistance?

In balancing a quadruplex why does the armature lever of the polar relay remain on either side with equal force when the balance is correct?

When the home battery is cut in why is it necessary to change the resistance in the rheostat.

What does it indicate when it is found difficult or impossible to centre the polar relay armature tongue?

Are condensers usually necessary to neutralize static discharges on short circuits?

What is the effect of induction upon the capacity of a wire?

What is the effect upon the relay of the discharge of static electricity from the line?

Where is the condenser placed, with reference to the other pieces of quadruplex apparatus?

When the condenser is properly adjusted what is its action upon the relay?

Why does the static discharge from the condenser neutralize that from the line?

If the polar relay responds to each motion of the home pole changer what does it indicate?

Study the various methods of obtaining a static balance.

After each station has balanced against the other, what further test should be made?

In testing for adjustments how is a correct balance indicated?

What is the effect upon the operation of the set when the pole-changer contact points are dirty or uneven?

Why do oxidized main contact points affect the working of a quadruplex?

Sketch of the Organization and First Reunions of the Old Time Telegraphers' and Historical Association and the Society of the United States Military Telegraph Corps.

BY COLONEL G. M. DUGAN, TIP TOP, KY.

[The records of the proceedings of the first ten meetings of the Old Time Telegraphers and the Society of the United States Military Telegraph Corps having been destroyed in the fire in the Western Union Building, 195 Broadway, New York, in 1890, Col. G. M. Dugan, one of the chief promoters of the Old Timers' organization, has kindly supplied the following brief account of those meetings from his own records. In 1897 Mr. W. J. Dealy, of New York, compiled the proceedings of the first four meetings, which were published in 1900 by the Association. In 1900 Colonel W. B. Wilson, of Holmesburg, Philadelphia, president of the Society of the United States Military Telegraph Corps, compiled the proceedings from 1885 to 1894 and for 1897, from notes and papers of those meetings which contained many valuable and important historical facts. This matter has, however, never been published.]

Early in 1880 a circular was sent out proposing a re-union of all old time telegraphers, and was signed by Anson Stager, vice-president and general superintendent, Western Union Telegraph Company, Chicago, Ill.; Charles E. Taylor, manager Western Union Telegraph Company, Frankfort, Ky., and J. A. Armstrong, manager, and J. C. Mattoon of the Western Union Telegraph Company, Cincinnati, Ohio, calling a meeting at Cincinnati for May 15, 1880. After some correspondence with those interested, the time was changed to September 8, the same year. The call brought together at the Burnet House almost one hundred veterans of the wire. The telegraphers of Cincinnati were very much enthused and spared no expense to make the meeting a success. At 11 a. m. on the day of the meeting carriages were in waiting to convey the entire party through the city suburbs. At the county workhouse a lunch was furnished by superintendent James Morgan, after which the party was driven to Chester Park to see the famous trotter, Maud S. An exhibition of her speed was given in a mile dash. A drive was then had through the different suburbs, Clifton, Avondale, Mt. Auburn, etc., to the Highland House, where a business meeting was held. It was presided over by the late James D. Reid of New York. A committee was appointed to arrange for a permanent organization. Adjournment was then taken until 8 p. m. at the Burnet House.

The adjourned meeting was called to order at 8 o'clock with J. D. Reid in the chair. The committee on permanent organization—Col. R. C. Clowry, J. J. S. Wilson and E. P. Wright—reported in favor of the following for permanent officers of the Old Time Telegraphers' Association:

President, O. H. Booth, Mansfield, Ohio; vice-president, Geo. M. Dugan, Jackson, Tenn.; secretary, J. C. Mattoon, Cincinnati, Ohio; treasurer, F. A. Armstrong, Cincinnati, Ohio. Niagara Falls was selected as the place of the next meeting, and the third Wednesday in September, 1881, as the time.

Eighty-eight members sat down to the banquet. The arrangement of the tables and floral designs was superb. The toast, "Telegraphy As It Was," was responded to by J. D. Reid. Mr. Wiley Smith, of Indianapolis, Ind., spoke of the origin of the meeting and traced it to a picture of James Leonard sent to General Stager. The meeting was a most enjoyable affair. Every one regretted the absence of Mr. Charles E. Taylor, who had been so enthusiastic in working up the meeting and who with others sent messages of regret.

There was no meeting in 1881 on account of the death of President Garfield.

The second meeting was at the International Hotel, Niagara Falls, September 20, 1882, with O. H. Booth in the chair. It was not so largely attended as the meeting at Cincinnati. The Military Telegraphers held a meeting at the same time and place and effected an organization with Mr. W. R. Plum of Chicago as president. It was here and then that a union of the two associations was brought about, as so many were eligible to both. Eleven members were added. The names of those who died since the previous meeting were James N. Ashley, B. H. Johnston, James K. Klegg and Alfred Gaither. The officers elected were: President, W. R. Plum, Chicago, Ill.; vice-president, W. B. Wilson, Lancaster, Pa.; secretary, J. C. Mattoon, Baltimore, Md.; treasurer, W. S. Chapman, Chicago, Ill. Chicago was chosen as the place of meeting in 1883. The banquet was at the International Hotel. The association numbered 140 members.

On September 19 and 20, 1883, the Old Time and Military Telegraphers had their meeting at the Grand Pacific Hotel, Chicago. The first business was the election of officers for the ensuing year, which resulted as follows: President, George M. Dugan, Jackson, Tenn.; vice-president, E. Rosewater, Omaha, Neb.; secretary and treasurer, S. B. Fairchild, St. Louis, Mo. St. Louis was selected as the place for the next meeting. General J. A. Logan addressed the Association. Forty new members were added to the list. A water set and tea service were presented to Colonel John C. Van Duzer, superintendent of the United States Military Telegraph during the Civil War. On the way to Chicago the following telegram was sent to Barney Hughes, Memphis, Tenn., urging him to attend the meeting:

"Barney Hughes, Memphis.

"One hundred and forty old timers say for you to meet them at the Grand Pacific Hotel, Chicago, on Thursday. Nothing but a personal apology to each and every one will excuse your non-attendance. Answer on train.

(Signed) "Hogshead, Dugan and Gaston."

This was the answer:

"To Hogshead, Dugan and Gaston, Centralia.

"Would I could gently embrace each veteran. The pleasure is denied me, and I feel a cemetery sensation. May the Lord and land-lord be merciful.

(Signed) "Barney Hughes."

This was the third meeting of the Old Timers and the first annual meeting of the Military Corps. The members who died since the previous meeting were: John E. Clark, Richmond, Va.; John H. Pierce, Clarkville, Tenn., and Major M. J. Waldron, superintendent U. S. mail service, Memphis, Tenn. The banquet was held at the Grand Pacific Hotel, and after a sail on the lake the party separated.

The fourth annual meeting took place at St. Louis, Mo., September, 1884, at the Laclede Hotel, President Geo. M. Dugan in the chair. Fifty-one members answered the roll call. After the president's address twenty-six new members were elected. Vice-president Rosewater was then called to the chair and made a few appropriate remarks. He presided during the rest of the meeting. O. H. Booth, of Mansfield, Ohio; G. W. Trabue, of Nashville, Tenn., both old time superintendents; also L. M. Paynter, a veteran telegrapher, died during the year.

In the afternoon both associations went on an excursion down the river on the steamer *Charles Morgan*. The banquet was held on the boat. The election of officers for the ensuing year resulted as follows: President, C. W. Hammond, St. Louis, Mo.; vice-president, Charles E. Taylor, Frankfort, Ky.; secretary and treasurer, S. B. Fairchild. Officers of Military Telegraph Corps were elected as follows: President, W. R. Plum (re-elected); vice-president, E. Rosewater, Omaha, Neb.; secretary and treasurer, J. E. Pettit, Chicago, Ill. (re-elected). The convention adjourned to meet in New York in 1885. Number of members, 175.

The Old Time and Military Telegraphers' Association held their fifth annual meeting at the Murray Hill Hotel, New York, August 20, 1885. C. W. Hammond presiding at the Old Timers' meeting, and W. R. Plum at that of the Military Telegraphers. The banquet was held at the Manhattan Beach Hotel, Coney Island, at 8 p. m. An around-the-river and harbor excursion took place the next day on the steamer *Sylvan Dell*, upon the invitation of Comrade Erastus Wiman, a fine lunch being served on board. Seventy-three new members were added at this meeting. Those who died since the previous meeting were: Anson Stager, Chicago; James Partrick, Philadelphia; Charles A. Gaston, Memphis. The officers elected by the Old Timers were: President, James D. Reid, New York; vice-president, C. S. Jones, Chicago; secretary and treasurer, W. J. Dealy, New York. The convention adjourned to meet at Cleveland the third Wednesday in August, 1886.

On August 19, 1886, the two associations met in the Board of Trade rooms, Cleveland, Ohio, J. D. Reid in the chair. Mr. Reid delivered a fine annual address. Fifty new members were elected. Mr. Charles E. Taylor read an address giving an account of the unveiling of James Leonard's monument at Frankfort, Ky., July 29, which was erected by the Old Timers. Mr. C. C. Hine of New York also read an interesting paper. The officers elected were: President, C. C. Hine, of New York; vice-president, Charles E. Taylor, Frankfort, Ky.; secretary and treasurer W. J. Dealy, New York, (re-elected). There was an excursion to Cottage Grove Lake and a banquet at the Stillman House. Philadelphia was selected as the place for the next meeting. Messrs. Dealy, Bruner and Hammond were appointed a committee to revise the constitution and by-laws and report at the next meeting.

On August 17, 1887, the associations met in Philadelphia in the Common Council Chamber. The address of welcome was delivered by W. B. Wilson. President Hine was in the chair and made a good address. The meeting was next addressed by Prof. David Brooks. Officers elected for the ensuing year were: president, Prof. David Brooks; vice-president, Irwin Dugan, Louisville, Ky.; secretary and treasurer, W. J. Dealy. The Military Telegraphers elected officers as follows: President, W. R. Plum; vice-president, Geo. C. Maynard of Washington; secretary and treasurer, J. E. Pettit of Chicago. Chicago was chosen as the next place of meeting. The members visited the Electrical Bureau, the Masonic Temple, the Mint, Wanamaker's store, Ben Franklin's tomb, the Zoological Gardens, etc. Fourteen new members were elected. The banquet was held at the Union League Club.

The Committee appointed to revise the constitution and by-laws reported, and the new constitution was substituted for the old. An excursion was taken on the steamer "Belmont" up the Schuylkill river. The membership now numbered 265.

August 15, 1888, the Old Time Telegraphers and the Society of the United States Military Telegraph Corps, met in annual session at Gore's Hotel, Chicago. In the absence of President Brooks, vice-president Capt. Irwin Dugan took the chair. Chas. E. Taylor, Frankfort, Ky., was chosen president: Day K. Smith, Kansas City, Mo., vice-president: W. J. Dealy, secretary and treasurer, and Louisville, Ky., was selected as the place for the next meeting. The members were invited by Mr. A. H. Bliss to go on 'change and in the afternoon they enjoyed a sail on the lake on the steamer *Josie Dawson*. The banquet was held at Kinsley's and was a most enjoyable affair. Messages and letters of regret were read from W. G. Fuller, W. B. Wilson, Clarence E. Stump, William M. Barr and others. The first toast, "Morse" was responded to by Mr. James D. Reid. W. R. Plum presided at the banquet. The Military Telegraphers re-elected the old officers and the meeting adjourned, each member feeling that nothing had been left undone by the local committee to make it most pleasant for all.

The eighth reunion was held September 11, 1889, at the Louisville Hotel, Louisville, Ky., Chas. E. Taylor in the chair. Resolutions were adopted on the death of George W. McCann of Meridian, Miss., and Mrs. M. H. Ogle who died at her post in the Johnstown flood.

Six new members were elected. The officers elected for the ensuing year were, president, Day

Digitized by Google

K. Smith, of Kansas City, Mo.; vice-president, Barney Hughes of Memphis, Tenn.; secretary and treasurer, W. J. Dealy. Kansas City was selected as the place of the next meeting. The Commercial Club took the association around the city in carriages in the afternoon and in the evening a banquet was held at the Louisville Hotel, the decorations being particularly artistic and appropriate. A telegraph instrument at one end of the table connected with the other and messages flew back and forth. Excursions were made to New Albany and to the Mammoth Cave, the party remaining at the latter place over night and returned to Louisville the next day. At an adjourned meeting held at the Mammoth Cave Hotel the Military Telegraph Corps re-elected the old officers. The convention adjourned to meet in Kansas City, Mo., in 1890.

The associations met in their tenth annual convention at the Centropolis Hotel, Kansas City, Mo., September 16, 1890. The meeting was called to order by Wm. Wiley Smith. He introduced Hon. Thomas F. Clohesey, a member of the Missouri legislature and an old time telegrapher, who made the address of welcome, Mr. A. H. Bliss of Chicago responding. Col. Van Horn of the Kansas City *Journal*, was the next speaker. President Day K. Smith then took the chair. A letter was read from Mr. J. D. Reid, then United States Consul at Dumfermline, Scotland, and was answered by cable by the association. A letter of regret from secretary Dealy was read telling of the fire in the Western Union Building in New York in which were destroyed all the records, collections, etc., of the Old Time Telegraphers' Association. Mr. W. H. Woodring, of Kansas City, was appointed secretary pro tem. A letter of regret from vice-president Barney Hughes was read. The committee was not satisfied and sent a message protesting, to which he replied as follows:

"Day K. Smith, President Old Timers.

"Your kind message supported by W. W. Smith and others received. The agony is mine, but sicknesss and absence of clerks excite me. Pity my sorrow."

(Signed) Barney Hughes, Vice-Pres.

Twenty-six new members were elected. Washington, D. C., the third Wednesday in August, 1891, was the place and time selected for the next meeting. Reminiscences by Messrs. Bliss, Crittenden, Lithgow, Follett, Pettit and others were given. There was an excursion to Leavenworth, the Soldiers' Home and Fort Leavenworth. The officers elected for the ensuing year were: President, Geo. C. Maynard, Washington, D. C.; vice-president, D. A. Williams; secretary and treasurer, W. J. Dealy.

The eleventh reunion took place at the Ebbitt House, Washington, D. C., August 19 and 20, 1891. The Old Time Telegraphers were called to order at 10 a. m. and president Geo. C. Maynard read his address. The first business was the election of new members, seventeen being enrolled. Mr. C. M. Heaton, Jr., had the honor of being elected by acclamation. He was then 87 years of age. He began his telegraph career in 1848. As a souvenir of his early work he exhibited the instrument he used when he started telegraphy. The officers elected were: E. Rosewater, Omaha, Neb., president; Geo. M. Dugan, Jackson, Tenn., vice-president, and W. J. Dealy, secretary and treasurer. Omaha was chosen as the place of the next meeting. An earnest appeal was made by the president to collect everything that would perpetuate the history of telegraphy. If the old time telegraphers failed to do this, much of the early history of telegraphy would be lost. The Society of the United States Military Telegraph Corps met at 2 p. m. After the adjournment the members visited some of the public buildings and other places of interest. Everywhere they went they found old time telegraphers. At the White House they met Mr. B. F. Montgomery who had received permission from President Harrison to open the building, which was then closed for repairs. Through the kindness of Mr. S. H. Kauffman, proprietor of the Washington *Star*, also an old timer, the Corcoran Art Gallery was visited and among the pictures which attracted attention was one by Professor Morse representing the Old House of Representatives in 1820. Mr. Kauffman was elected a member of the association. At 8 o'clock the members gathered in the National Rifles Armory for their annual reunion and banquet, President Maynard officiating. There were speeches from the heads of the various Government departments and from all quarters of the country came greetings and congratulations. The clicking of the instrument on the platform made a fitting accompaniment to the speeches. During a momentary lull one of the members in the back of the room jumped to his feet with the remark: "Mr. President, did I not hear the word come on the wire that we were to be connected with the City of Mexico?" He was right, and a moment later a message was clicking over the long circuit. The receiving operator was sitting on the platform with the assistant secretaries of the government departments around him and a delighted audience in front. From the operators in the City of Mexico came the following:

"To the Old Timers and Military Telegraph Corps:

"The operators in the land of the Montezumas send warmest greeting. Buenos Noches."

(Signed) City of Mexico.

When the message was read it was received with hearty cheers. The circuit was then changed at the general office and every minute or two messages were received from different parts of the country. Among them one from Gen. Thomas T. Eckert, A. B. Chandler, James Merrihew, and others. Greetings came from Augusta, New Orleans, Atlanta, Pittsburgh, Chicago, Cincinnati, New York, El Paso, Los Angeles, Philadelphia, St. Paul, Omaha, Buffalo, San Francisco, Ogden,

Digitized by Google

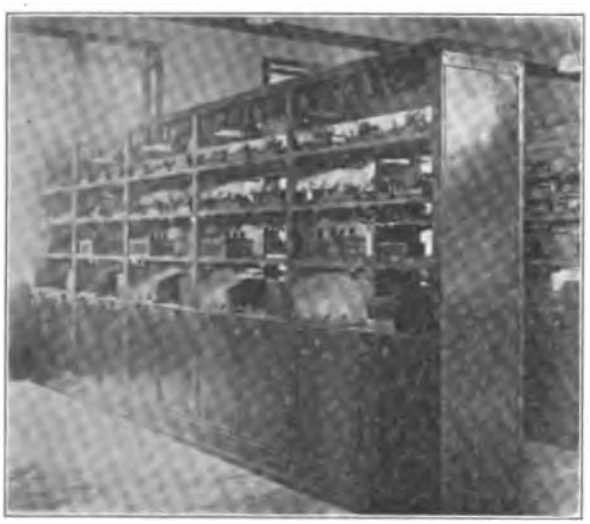
Portland and other cities. Among the speakers of the evening were Mr. M. M. Parker, president of the Board of Trade, Mr. W. W. Burhans, of the United Press, Col. Whitfield representing the Post Office department, Assistant Secretary of Agriculture, Wittels, Assistant Secretary of War, U. S. Grant, Prof. J. E. Watkins of the Smithsonian Institution and Mr. H. B. McFarland. Short talks were given by R. B. Lewis, O. S. Safford, A. H. Bliss and J. E. O'Brien. A paper by Mr. J. D. Reid, one of Morse's early associates was read. It was nearly midnight when the circuit was cut off and the Old Timers left the armory. During the exercises an elegant supper was served. The next morning, Friday, August 21, the members proceeded to Mt. Vernon and a picture of the party was taken on the grounds. A gavel of wild cherry wood grown on the place was bought for the association. The party returned to Washington and most of them left for home that evening, thus ending one of the most enjoyable of all the many pleasant reunions.

The Postal Telegraph Sectional Repeater Table.

BY A. P. ACHIMORE, NEW YORK.

Accessibility, compactness, flexibility and inflammability are the distinctive features of the new unit section repeater tables which the Postal Telegraph-Cable Company has installed in its new Buffalo office and elsewhere.

These tables are constructed of channel, angle and sheet iron and consist of four shelf sections,



VIEW OF SECTIONAL REPEATER TABLE.

each section having at its top a vertical strip upon which is mounted the ground main line and battery switches. Beneath the bottom shelf the wiring cabinet is located.

A unit section will take either two quadruplexes, four duplexes or four repeater sets. The vertical arrangement of instruments is a desirable feature in that it brings all parts of any set within easy reach for adjustment.

The wires connecting the instruments, switches, coils, etc., are carried through the ducts formed by the iron framework. Mounted inside of the ducts, flush with the bottom of the sheet iron openings, are truss rods which insure rigidity and avoid injury to the wires drawn over them.

Instrument interchangeability is a factor well considered. Owing to the narrowness of the unit, all instruments are mounted at the edges of the shelves so that they can be removed and replaced without difficulty.

With the same capacity and length as the old standard repeater tables the new type takes only one-third the floor space.

These tables were designed in the engineering department of the Postal company upon lines suggested by chief engineer Mr. M. M. Davis.

Andrew Carnegie and the Telegraph.

Mr. David Homer Bates, secretary of the Society of the United States Military Telegraph Corps, New York, delivered an address on "Andrew Carnegie and the Telegraph" at the banquet on the occasion of the fiftieth anniversary of the founding of the United States Military Telegraph Corps, at Atlantic City, N. J., September 7. He gave a very interesting description of Mr. Carnegie's early career, and his connection with the telegraph.

"Andrew Carnegie," said Mr. Bates, "not only became an expert operator, but he had the student habit—his mind was active, he attended night school, studied grammar and composition, read much and sent letters to eastern newspapers, giving local news. He once wrote to the Pittsburgh *Dispatch*, attacking the rules of Colonel Anderson's semi-public library, signing his letter "A Working Boy." The publication of this letter led to a change in the rules, allowing any working boy to have the use of the library.

"In February, 1853, Col. Thomas A. Scott offered Carnegie $35 per month to enter the railroad service. This increase from $25 was facetiously referred to by Mr. Carnegie years afterwards as the 'best X raise' that had ever been applied to him."

After describing Mr. Carnegie's services during the Civil War and his interest in the telegraph corps, Mr. Bates said that Mr. Carnegie believed himself to be the third person to shed his blood in the Civil War, the two others being enlisted soldiers in the Baltimore riots on April 19, 1861, Mr. Carnegie's sanguinary flow being caused by a broken telegraph wire, which he tried to repair near Washington, springing back and striking him in the face.

Mr. J. W. McMahon, district commercial manager of the Western Union Telegraph Company, New York, in renewing his subscription for another year, writes: "I take pleasure in renewing my subscription to TELEGRAPH AND TELEPHONE AGE, which I consider the best medium, if not the only one for the telegraph fraternity, to keep in touch with the practical and progressive side of the profession, not to mention the social and personal notes which make interesting reading."

CHANGES OF ADDRESS.—In ordering a change of address the old as well as the new address must be given.
REMITTANCES to Telegraph and Telephone Age should be made invariably by draft on New York, postal or express money-order, and never by cash loosely enclosed in an envelope. By the latter method money is liable to be lost, and if so remitted is at the risk of the sender.

October 1, 1911.

Relations of the Telegraph Companies and Their Employes.

On April 6, 1910, the executive committee of one of the telegraph companies passed the following resolution:

"This committee recommends to the Board of Directors that no increase in the present rate of dividends be made until the plant of the company wherever it may be found necessary, is placed in the highest possible condition, the working conditions of the employes improved and their salaries rearranged, recognizing in this readjustment merit, proficiency and length of service modified by location."

This resolution was adopted eighteen months ago and the question now is, "Has the company carried out the recommendations of its executive committee?" It has had ample time to prove its sincerity, and we do not think that there can be any question that it has lived up to the letter and spirit of the resolution to adjust irregularities in the wage scale and otherwise improve the condition of its employes. In order to do this it has kept its dividend rate down to the minimum point and has endeavored to bring its operating plant and force up to the highest state of efficiency. Salaries have been generally advanced on the basis of merit, proficiency and length of service, and on the whole there seems to be a reasonable degree of satisfaction in the ranks.

From careful inquiries that have been made there is no doubt in the minds of the employes that the telegraph companies have certainly endeavored to treat them fairly and will continue to do everything for their welfare as rapidly as circumstances permit, and it is with much satisfaction that we note this favorable attitude. More gratifying is the fact that the employes not only fully recognize the efforts that the companies are making in their behalf, but are fully disposed on their part to be fair and give full consideration to the fact that their own interests can be best advanced by advancing the interests of the company which employs them.

Everything we have, or can legitimately have, is the result of an equitable division of the fruits of our labor, bearing in mind that it is as necessary to yield to the employer as it is necessary for the employer to yield to the employe, each considering the other's interest, otherwise an equitable basis cannot be established satisfactorily to either party. If this law is kept in mind, much dissatisfaction and unnecessary friction can be avoided. It is therefore gratifying to know that the resolution referred to was adopted in good faith by the company, and that there has been established a strong co-operation between the company and its forces by reason of the fact that the employes have confidence that the company has and will continue to carry out its policy in order that its own interests and the interests of its employes may be further advanced by virtue of the policy outlined in the resolution previously referred to.

The Best Way to Obtain an Increase in Salary.

In these days of competition in business the man with knowledge is the one who is in demand. Knowledge in business is capital, and is just as essential to carry on a business enterprise as is money—one is of little value without the other.

The desire to acquire wealth and power seems to be universal, and it is possible to realize this ambition only by the extension of knowledge. Knowledge, of course, cannot be bought; there is only one way to acquire it and that is by individual study and an equivalent expenditure of mental energy. Knowledge is the lever by which a man can raise his salary. Those who hold positions of prominence and trust in the telegraph and telephone service occupy them by reason of sufficient knowledge to fulfill the duties. If they cannot fill these positions their weaknesses are soon found out and they must step aside to make way for those more competent.

There is no easier way to acquire knowledge than to study, and if a man is not willing to study he should not complain because he is left behind in the world's progress. He that would win a race must run. There are many employes in the telegraph service who would like to occupy higher positions and receive larger salaries but are not willing to exert themselves to attain their ambitions. They sit idly by and see others forge ahead through habits of industry and the improvement of their minds and then perhaps complain that unfair means have been employed against them. The telegraph and telephone companies need men who really know things, and who can prove their knowledge. "By their fruits ye shall know them."

The most effective way for an individual to obtain a greater income is simply to make his services so valuable that employers will bid for them, and this possibility is open to all without prejudice.

We have in mind an instance in New York

Digitized by Google

some years ago where an operator fitted himself for a better position by diligent study during spare moments and the burning of midnight oil. He left the telegraph service where he was getting a salary of $80 per month and in two years afterwards was receiving $5,000 a year. Another case is that of an operator who fitted himself for something better and is now general manager of a prominent telegraph company. A great many other instances could be cited where successful and prominent business and professional men began their careers at the key, and by diligent study and close observation have reached the high positions they now occupy.

Again we state that study, with a sincere determination to succeed, will place any man on the road to success. Telegraphers should study their vocation in its technical side so that they will know the reasons for the things with which they are brought into daily contact.

Telephone Pioneers.

The development of the telephone is indeed a marvel in modern industrial history. The growth of the art has been phenomenal and it has all taken place in thirty-five years. A great many of the men engaged in telephone work to-day witnessed the birth of the telephone in 1876 and now they have paused long enough in their activities to realize that they are pioneers in one of the greatest industrial developments the world has ever known. Usually an industry of such magnitude represents the accumulated wisdom and experience of generations, but not so with the telephone. Its wonderful development has been so rapid that most of the pioneers are still alive and they will be heard from after this through the instrumentality of a social organization to be known as the "Telephone Pioneers of America."

The old time telegraphers have a social organization, but practically all of the real telegraph pioneers have joined the great majority. Many of the telephone pioneers have yet many years of useful life before them and in their proposed organization they will derive much enjoyment in meeting and recounting the experiences of the past.

The formation of the society is being attended with much enthusiasm, and the first meeting, which will be held in Boston, November 2, 3 and 4, will no doubt be an extraordinary event judging from the elaborate preparations now being made for it.

The Beginning of the Telegraph.

An interesting contribution to telegraphic history from Mr. Walter Vail will be found on another page of this issue. It gives some details of the early work which perhaps are not generally known and gives the dates of some of the principal events connected with the institution of Morse's first telegraph line. It is amusing at this day instruments the difference is striking in- and Vail on the first line weighed 185 pounds each. It is surprising that they worked at all against such physical odds, but it is a satisfaction to know that one of them has been preserved as a historical relic. Compared with the present-day instruments the difference is striking indeed, but the prototype was no different from its more refined successor in principle.

Instruction in Telegraphy.

A complete course of instruction in telegraphy will be published in these columns, beginning October 16 or November 1. It will be very practical and will meet the needs of telegraphers who are ambitious to fit themselves for advancement in their work. This will be one of the most valuable features ever provided by this journal for the benefit of its readers.

Letter Telegrams in Germany.—Letter telegrams are to be introduced in Germany on October 1. They may be sent at any time between seven in the evening and midnight for delivery with the first mail, between seven and eight the next morning. The cost is 1 pfennig (about one-fifth of a cent) per word, with a minimum charge of 50 pfennigs per message. It will be possible to send a letter telegram of 100 words over long distances for 1 mark (25 cents). The rate is the same for all points in the German Empire.

National Electrical Code.—The 1911 edition of the rules and requirements of the National Board of Fire Underwriters for electric wiring and apparatus is a booklet of 190 pages and covers every application of electricity. Mr. Ralph Sweetland, Boston, Mass., is secretary of the Electrical Committee.

Telegraphers of Today.

An excellent opportunity is offered to telegraph people in general to become acquainted with over 600 prominent telegraph officials and others identified with the telegraph, the railroad, the submarine cable service and press associations of the past generation, through their portraits and sketches of their careers as published in "Telegraphers of Today."

This work was issued in 1894 and includes biographical sketches of all the individuals connected with the interests mentioned at that period, many of whom have passed away from their earthly labors. The younger generation, however, will find much of interest in looking upon their portraits and reading of their achievements in life. Many of them are still alive and in harness, in the telegraph and other fields of activity.

This book, which is 11½ x 14 inches in size, was originally published at $5 per copy, but in order to close out the remaining copies we offer them at $1 per copy by express, charges collect.

Send orders to TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

Recent Progress in Telephone Transmission.

In a paper read before the Philadelphia Telephone Society, Mr. H. Mouradian, engineer, gave some interesting facts regarding recent progress in telephone transmission. Following are some extracts from his paper:

The art of telephonic transmission is considerably more difficult and intricate than the art of power transmission, because we have to deal with a larger number of limiting factors. The limitations in the way of the telephone engineer are many. When speech is transmitted over a pair of telephone wires, the energy gradually dwindles and may be insufficient even to put in motion the diaphragm of the telephone receiver. On what is called a thirty-mile connection, which is generally assumed to be the limit of ordinary commercial transmission, the energy at the receiving end is about 1/1000 part of the input of energy at the outgoing end.

The limitations under which we suffer that do not affect the power engineer are—

1. We cannot raise the energy input at the outgoing end above a certain point without producing interference on adjoining circuits—what in telephone language is termed cross-talk.

2. We have to deal with the dissipation of current as we go along from the transmitting end of the line to the receiving end.

3. We have to transmit a large number of different kinds of speech current, each having a different pitch.

The dissipation of the current as we slide along the telephone line is due to the electrostatic capacity of the line. It is due to the transmission of speech currents from one wire to the other through the medium of the so-called ether in the air. It is the same medium that wireless engineers utilize for transmitting wireless messages. The higher the pitch of the telephone speech currents the more readily they will utilize this medium and the more dissipated will be the telephone current.

I thought I could not present the effect of this factor better than by assuming that it did not exist and estimating the increase in the range of transmission that would be thus made possible. Table I shows this limitation:

TABLE I.

	Present limit.	Limit assuming no electrostatic capacity.
No. 19 gauge cable....	30 miles	130 miles
No. 8 B. W. G. copper wire (non-loaded)...	1,000 miles	3,500 miles

These figures indicate clearly how detrimental to transmission is the effect of capacity. Some means were necessary to overcome this effect, and the answer came in the form of the process known as "loading." It is interesting to note that as early as 1885 Oliver Heaviside had indicated the beneficial results that could be obtained if telephone wires had a larger amount of inductance than they have. He did not show how telephone wires could be made to have a larger inductance. It remained for Dr. Pupin to show us in 1900 the manner in which this could be accomplished.

We owe to Dr. Pupin the following basic ideas:

1. The loading coil—which is an inductance coil—having a closed magnetic core of soft iron.

2. The idea that a non-uniform line made of a uniform line and loading coils inserted at regular intervals depending upon the constants of this uniform line and the amount of loading desired to secure, could be made the equal of a uniformly loaded line, theoretically ideal line, when every foot of line has the same constants as the preceding and succeeding sections of the line of the same length. He not only gave us the tool but showed us how to use it.

Table II shows the increase in efficiency which it has been possible to secure with various types of cable and open wire circuits by the use of loading coils.

TABLE II.

	Attenuation Factors.		Increase in Efficiency.
1. Cable Circuits.	Non-Loaded.	Loaded.	
19 gauge (.080)	1.216	0.31	390%
16 gauge (.072)	0.800	0.19	420%
13 gauge (.072)	0.577	0.13	440%
2. Open Wire Circuits.			
No. 10 B. & S.	0.080	0.035	230%
8 B. W. G.	0.035	0.015	230%
8 B. W. G. phantom	0.029	0.013	220%

The percentage figures indicate also the increase in the range of transmission due to loading.

The progress in transmission made during the last two or three years consisted in:

1. The development of the duplex cable.

2. The development of phantom loading coils for open wire and cable work.

3. The development of porcelain insulators.

4. The loading of submarine cables.

Each of the above items represents an important advance in the art involving a considerable amount of engineering skill and ability. The development of the porcelain insulators represents the real progress made in the extension of the transmission range, while the other items are more significant from the standpoint of better utilization of materials.

In addition to the above the telephone repeater is forging ahead and improvements in the efficiency of our substation apparatus appear certain of realization.

The "duplex" or "phantom" cable is a cable in which the individual conductors are not only twisted together to form a pair, but the cable pairs are twisted together two by two to form a phantom. The two pairs which are twisted together are termed the "side circuits." The two side circuits are given different lengths of twist. The length of twist of a phantom circuit is also different from the length of twist of either one of its two side circuits.

The use of a duplex cable enables us to obtain

Digitized by Google

50 per cent. more pairs in the same lead sheath than is possible with ordinary cables. We cannot, however, secure, for the same total number of circuits, a saving of 33 per cent. in first cost, as it is necessary to load not only the side circuits but the phantoms as well. The phantom loading coils cost more than the ordinary loading coils as they have to be made more efficient. In addition when standard common battery supervision has to be furnished over the cable, special composite signaling apparatus is required which still further increases the cost.

The possibility of loading a phantom is easily understood, if it is assumed that in a circuit made of two side circuits, each provided with a loading coil, one-half of the loading coil winding in each side circuit is reversed. A phantom loading coil will therefore have four windings. We will secure the desired result of "loaded" side circuits and "loaded" phantoms by the use of two distinct sets of loading coils,—1. Side circuit coils, 2. Phantom coils.

The presence of side circuit coils is a detriment to the efficiency of the phantom circuit. The presence of the phantom loading coils is a detriment to the efficiency of the side circuits. To reduce the transmission losses due to the simultaneous presence of the double set of loading coils, a new type of side circuit loading coil was designed, which was provided with four windings instead of two—these four windings being associated in such a manner as to eliminate the presence of positive and negative magnetic poles. Side circuit loading coils designed in this manner act practically as non-inductive resistance, so far as the phantom circuit is concerned, and are considerably better balanced than the loading coils used in conection with non-duplex cables. To obtain an economical and well-balanced phantom loading coil the four windings were combined on a single core. Furthermore, application was made of the same principle as followed out in the design of side circuit loading coils—this application resulting finally in phantom loading coils provided with a single core and eight windings.

The new feature in the balancing of the windings of these coils was absolutely essential to the problem of securing phantom loaded open wire circuits which would be reasonably quiet. If it were not for this feature, the loading of the side circuits in the quadded pairs in the New York-Washington cable would have brought in additional transmission losses in the phantom circuits.

Spark Gaps or Oscillators.*

The oscillator or spark gap is one of the most important yet often the most poorly adjusted part of a wireless station.

To obtain a good oscillatory discharge with little damping it is necessary that the resistance of the circuit should be kept low, and since the greatest part of the resistance is in the spark gap it would appear as if this must be very short. While there are reasons for keeping it short there are on the other hand very good reasons why it should not be made too short, and the proper length should be a sort of compromise to be determined by experiment.

If the gap is too short, the discharge will form an arc and the only oscillations taking place will be those corresponding to the frequency of the charging current. Power consumption is also in favor of a long gap, since it causes the induction coil or transformer to draw less current from the line. Another argument in favor of a long gap is the fact that the condenser is charged to a higher voltage and more energy stored up, which makes a greater distance of transmission possible. But as stated (and there always is a tendency for the amateur operator to open out his gap as long as the sparks will continue to jump steadily) the discharge will not oscillate but will merely set up an undirectional current.

There exists a proper gap length for a given circuit which will cause that circuit to emit a maximum amount of energy and which may be determined accurately only by means of a hot-wire ammeter placed in the aerial circuit. The proper gap length is then indicated by the maximum deflection of the meter.

The correct adjustment of the gap may be approximated by the experienced operator. If too short, the spark will be hissing and flaming and is in extreme cases red or yellow colored. It should be lengthened out until it is thick and white and a slight increase in sound is noted. The spark should not be, as commonly thought, stringy and crackling.

Arcing is often caused by insufficient condenser capacity in the circuit. But if the capacity is increased to remedy the arcing, the gap length should also be increased or otherwise the potential of the condenser may not be sufficiently raised to permit a disruptive discharge to take place.

*From "Wireless Telegraph Construction for Amateurs." By A. P. Morgan.

Evening Technical Instruction.—The college of engineering of the Polytechnic Institute of Brooklyn, N. Y., announces for the season of 1911-1912 a series of evening and Saturday courses in engineering, chemistry, physics, mathematics, drawing, history, economics and languages, especially designed to afford men in active practice opportunities for professional study. Among the electrical courses are: electricity and magnetism; electrical measurements; electrical design and electrotechnics, the latter covering electric transmission of intelligence. There are seventy-three courses in all covering the entire range of subjects enumerated. These courses provide an excellent opportunity for telegraph and telephone men to become instructed in the technical side of their work. The Institute has issued a booklet giving full information on the subject, a copy of which may be obtained on application.

Moral Conception.

BY F. E. D'HUMY, NEW YORK.

Mankind has been endowed with moral conception from time immemorial. Wonderful has been the mental and moral development of man since the time he opened his bewildered eyes to the marvels of this earth; but while advancement has been certain, it has been slow.

Comparing the present generation with the past, the advance may not be discernible, or even when we look back many generations, no distinct line of advance may be discovered. This difficulty of measuring mental and moral development in steps of generations cannot be taken to mean that these endowments are limited in degree and that man's conceptions of morality are the same to-day as those of his cave-dwelling ancestors, and that man many thousands of years hence will possess moral views no greater than those of present life.

Moral advance has been so gradual that it is necessary to take a retrospective view of the subject extending over many generations, to detect the evidence of progression. Advances in ethics come to light more perhaps by changes in customs and the adoption of new laws, or the revision of old ones, than through any other channel. While a change in a custom or the making of a new law may register an advance, it does not necessarily indicate the epoch of such advance. The moral development so recorded is necessarily evolutionary, therefore it extends back to an indefinite period, beginning with immeasureable nothingness.

Advanced we have, and advance we must. It is impossible that we are here for no purpose. Life, thought, time, in fact every conceivable thing or effect, is but a factor and stage in evolution. Evolution means progression.

It is true that general progression may mean the retrogression of some things—the undesirable things—and even the complete obliteration of them, for there is nothing truer than the law of the survival of the fittest.

It is not necessary to look backward to learn that the present is only a link in man's moral progression, for it is evident everywhere on the earth. We find it in comparisons of classes and of races of today. We know that those of cruder moral sense are gradually but surely elevated by contact with those of higher moral sense. If contact be continued over a period of many generations the benefits are correspondingly great and become more firmly established proportionately.

This contact development is most evident to us Americans in the moral change for the better of the negro by association with the white.

The upward trend through the influence of the higher over the lower is evolving universally. Those nations with the highest ethics uplift the nations that are lower in the scale; the communities of a nation having the highest moral sense similarly influence other communities of the same nation possessing a lower moral sense, and so on down to families and to individuals.

Moral advancement thus not only finds its path through group-relation, but also through individual-relation. In fact it has its origin in the latter. The responsibility, therefore, of every human being is very great. This responsibility is greatest in the head of a family, or in any person having influence over others.

It is of extreme importance to the moral advancement of mankind that everyone be made to realize his individual responsibility in this respect. It should be the duty of those controlling publications to continually keep this thought before the public so that it will take root with ever-increasing firmness.

The employer, the corporation head, the corporation chief of department, etc., in fact anyone and everyone in control of employes, whether the number be large or small, is placed in a position of tremendous moral trust.

The moral responsibility toward the employe is no less than the commercial responsibility of the position held. In fact, the successful administration of the position demands that it be equal.

The vast army of workers of the world toil under the direction of leaders variously classified. These leaders carry a very large burden of moral responsibility. The responsibility may be considered proportional to the number of individuals controlled.

The exercise of leadership of any degree, from the administrative heads of a large industrial enterprise down to the minor chiefs of departments, should demand constant care and the exercise of fine judgment in adjusting affairs to equitably distribute the burden of the world's work between the producer and the consumer.

To secure the ideal balance is perhaps the most difficult task confronting those in command of the industrial field to-day, but its nearest approach can be hopefully looked for in the sound development of the so-called trust, which with its well organized technical forces is in a position to make investigations that will determine within a reasonable degree of accuracy the various lines of division involved in such a problem.

A corporation's responsibility is divided between its stockholders, its employes and the consumers of its product. It must purchase the materials it uses at fair rates, it must adjust the compensation of its employes to permit them to live in a degree of comfort that will insure happiness, moral advancement and maximum efficiency, and for this it must exact a fair return. The internal affairs must be such as to eliminate all waste and to secure maximum efficiency in production. Marketing its product or service must involve economic means only so that the efficiencies of production are not unduly counteracted. An expenditure for publicity is essential, but should be no more than that necessary to make known to the public the existence and advantage of the product or services to be furnished. Extravagant displays and exaggerated statements in advertisements are not fair to the consumer, and as moral development in commercialism develops, must

Digitized by Google

discontinue. The costs of publicity and marketing should be paid for by the consumer, and in no way by the producer, such as by a condition of cramped dividends to the stockholders or of cramped compensation to the employes.

To the cost of production, publicity, marketing, and insurance, must be added an amount that will give to the stockholders a fair return on their investment. The latter is also a factor requiring the most careful study, for the moral responsibility to the stockholder is no less than it is to the consumer or to the employe. This factor is also one very difficult to determine, as it is dependent on many conditions, such as the value of money at the time of initial investment and of its present value; the degrees of initial and present risk; the period of unearned dividends, etc., and perhaps pluck, and creative and administrative ingenuity may justly come in for consideration.

Every employe should learn to feel his moral responsibility. The part every individual takes in the make-up of a corporation's personnel is important, even down to the lowest employe in the ranks. The moral responsibility of the one at the bottom of the ladder is greater than may perhaps seem to be at casual glance. It is for each individual to find out his own capabilities and capacity, and to then use them to the best advantage for his employer, to a point governed only by the limit of efficient endurance. To secure this ideal the individual must be ever on the alert to see that the methods governed by personal characteristics are netting the best results, and if they are not, to change them by diligently watching self and training accordingly.

As there is always a possibility of one being prejudiced in favor of one's self, it is always safer to give more of one's own effort than what may be believed to be a fair equity for compensation received. To carry such a plan to excess is necessarily evil, as it narrows the opportunities of personal development and takes away from self and one's family the advantages that would otherwise be derived by such development. It is equally unfair to the employer, as it limits the sphere of usefulness to present occupation.

The responsibility of the man in the ranks does not stop here. It also lies in his attitude to others—to the members of his family, his co-workers, his employers and to the consumers of the product he is assisting to create. Much good can be done by the proper attitude and much evil by the wrong.

When the individual emerges from the ranks and finds himself in charge of employes, his responsibilities increase to a point where it will no longer do to merely give good measure of self to be sure one is right, but he must carefully see that an unfair amount is not exacted from his subordinates, yet be very sure that a fair amount is received from them.

Together with the ethical responsibility of apportioning the burdens and fruits of an enterprise among stockholders, employes and consumers, there is the moral effects of personality of each individual that comes in for a very important part and which should be carefully guided so as to reflect good and happiness among all within range.

As the advancement of ethics is made through the channel of contact or environment, the individual can only be successful in his duties to mankind and the world by being considerate of, and kind, upright and just to all with whom he comes in contact, be it relative, companion, co-worker, subordinate or superior. He must not be satisfied to merely affect these qualities but must actually possess them, think and live them, and feel them in his heart. They will then be reflected in others, who in turn will reflect them again, like so many mirrors with ever-multiplying effect. The reflecting power of some of the mirrors may not be very good at first, but their surfaces are bound to become gradually more perfect by the continual impingement of purer rays of thought.

It is thus possible for every one of us to add to the foundation of moral obligations these fundamental principles, upon which will be built the finer superstructure of the perfect man.

Maver's American Telegraphy.

The new and enlarged edition of Maver's "American Telegraphy and Encyclopedia of the Telegraph," known as the 1909 edition, is probably the most complete text-book on telegraphy which has ever been written. Among the important additions to the work in this edition are descriptions of the Barclay Long Distance Printer, as operated on the lines of the Western Union Telegraph Company, and the Murray Printer, as now used in Europe. This book is a library on telegraphy, simultaneous telegraphy and telephony, on wire and cable testing, etc. It is used as a text-book and a book of reference in many of the largest universities, and the large telegraph and telephone offices in this country. It contains within its covers a complete elementary treatise on electricity and magnetism, primary and storage batteries, line construction, etc. The beginner may successfully peruse his studies of these subjects by means of this book without reference to any other work. This statement is attested to by many successful telegraph and telephone engineers who gratefully term the book their Alma Mater. The book is written in simple English, and is practically without mathematics. No aspiring student in the telegraph or telephone ranks can afford to be without it. This fine work will be sent to any address, carrying charges prepaid, on receipt of price, $5.00, by J. B. Taltavall, Telegraph and Telephone Age, 253 Broadway, New York.

Western Union Dividend.—The directors of the Western Union Telegraph Company on September 13 declared the usual quarterly dividend of three-quarters of one per cent., payable October 15.

Line Conductor Requirements for Telegraph Transmission.

At the recent convention in Boston of the Association of Railway Telegraph Superintendents, Mr. Frank F. Fowle of Chicago read a valuable and interesting paper on "Line Conductor Requirements for Telegraph Transmission." A portion of this paper was printed in our issue for July 16.

The following abstract from the same paper relating to the effects of relay adjustment and the effects of terminal resistance will be read with special interest by practical telegraphers.

EFFECTS OF RELAY ADJUSTMENT.

The ability of an operator to adjust his relay properly for working on low margins is an important factor. This is a matter of instruction and education, primarily, but in order to show its importance the following values of the operative limits with a 10-ohm line have been calculated (see Table I):

An increase in the margin from 12.5 to 15.0 milliamperes, for example, caused by the operator's lack of knowledge or skill, drops the operative limit from

TABLE I.

—Currents, in Milliamperes—			Value	Operative Limit,
Operate.	Release.	Margin.	of n.	in Miles.
50.0	40.0	10.0	5.00	335
50.0	37.5	12.5	4.00	299
50.0	35.0	15.0	3.33	269
50.0	32.5	17.5	2.96	249
50.0	30.0	20.0	2.50	221
50.0	25.0	25.0	2.00	181

299 miles to 269 miles; or a 20% increase in necessary margin shortens the line 10%. Other examples can be easily computed from the table, but the essential point is to secure the lowest possible margin for commercial service.

EFFECTS OF TERMINAL RESISTANCE.

In order to show how the increase of terminal resistance decreases the operative limit, the following calculations have been carried out for a line of 10 ohms per mile, assuming as before that n has a

TABLE II.

Terminal Resistance, in Ohms.	Operative Limit, in Miles.
0	326
100	317
200	307
300	299
400	291
500	283
600	276
800	262

value of 4.00. The results are given in Table II for terminal resistances ranging from nothing up to 800 ohms.

The ideal value of terminal resistance is zero, and a value of 300 ohms cuts down the operative limit from 326 miles to 299 miles, or 8.3%. A resistance of 600 ohms cuts down the limit 15.3%.

In this respect generators are more efficient than gravity batteries, because of their low internal resistance, and in comparing the cost of the two for equal transmission distances, the battery will require a slightly larger wire for equal results and should be charged with the additional cost. This produces a more favorable showing for generators, or dynamotors, than the comparison of actual cost leaving the line out of consideration.

The advantages of generators can be quite largely sacrificed by the use of lamps of unnecessarily high resistance in the taps, and it is important to keep the lamp resistance at the lowest point consistent with safety. Carbon filaments should not be used, because their resistance decreases with the increase of current; iron, on the other hand, possesses the opposite characteristic and is quite satisfactory.

Keeping a Switchboard Dry During a Flood.—During a recent flood on the Allegheny and Monongahela rivers at Pittsburgh, Pa., the private branch telephone exchange switchboard in the Colonial Hotel was threatened by the rising waters. It was placed beyond harm, however, by setting it on some beer kegs that were floating about and later, as the water continued to rise, the board was further "jacked-up" by means of cross arms placed on top of the kegs. In this way the board was kept dry and in an operative condition.

A Few Testimonials.

Mr. W. O. Snyder, a well-known old-time telegrapher, now a resident of Fairfield, Conn., in renewing his subscription writes: "I enclose check for my thirtieth year's subscription. I have watched the growth of the publication from its infancy to maturity, with pleasure and pride, until it really seems that perfection has been reached. Yet I know that a year hence it will be better than now, and that is my earnest hope."

Mr. C. F. Mason, district commercial superintendent of The Pacific Telephone and Telegraph Company, Los Angeles, Cal., in remitting for the renewal of his subscription writes: "You have shown your usual good judgment in renewing my subscription to TELEGRAPH AND TELEPHONE AGE, as the paper is indispensable to a telephone or telegraph man."

Mr. N. E. Smith, superintendent of telegraph of the New York, New Haven and Hartford Railroad, New Haven, Conn., in renewing his subscription to TELEGRAPH AND TELEPHONE AGE writes: "I am very glad you continued my subscription as your publication is of too much interest and value to be dispensed with."

Mr. Chas. E. Stump, manager of the branch office of the Postal Telegraph-Cable Company at 105 Dock Street, Philadelphia, writes: "I enclose you my check for $2.00 to insure me another year of good 'Telegraph News.' Couldn't well do without the AGE after being a subscriber for the past twenty-eight years. Keep it coming."

The Storage Battery in Municipal Service.*

BY H. M. BECK OF CHICAGO, ILL.

With the adoption of storage batteries in different classes of service, the manufacturer is regularly confronted with the same problem—the difficulty in showing that in the end the most economical method is to give a battery the proper care and operation, even at some little expense, and that this is essential if satisfactory results are to be obtained. The tendency is just the reverse, rather to allow the cells to run just as long as possible without attention, and it has often required a costly experience to bring about the needed reform. The best battery can be ruined in a year, or even less, where it would have given many years of service with proper treatment.

There is a marked difference between a storage battery and apparatus of mechanical nature. When some part of the latter gives out, the whole machine is apt to stop work and necessitates immediate attention. With the storage battery, however, this is not the case. It does not give out suddenly, but will continue to operate long after it should have had attention. If it is allowed to go on working in this condition, however, when it does finally fail, the plates are likely to be seriously damaged, if not ruined.

The characteristics or indications commonly used for governing the operation are voltage, specific gravity, gassing and efficiency. Of these, the first two, voltage and gravity, give by far the most accurate results, and the others are only applicable as checks or where accurate operation is not essential.

Voltage and Gravity.—When charging, the voltage and specific gravity readings gradually increase until the cells are fully charged. They then come to a standstill and will not show any further increase, no matter how long the charge is continued. It is to be especially noted that as long as the cells are taking charge the readings increase, that when the cells are fully charged the readings cease rising, and that the final values reached vary widely at different times. In other words, a battery may be at different times in exactly the same state of charge, although the actual voltage or gravity readings are entirely different.

During discharge the voltage and gravity readings fall. We have learned from experience that it is dangerous to the plates to discharge them below certain values, and these are, therefore, arbitrarily fixed as the minimum discharge limits.

Gassing.—Until nearly charged, the plates absorb the energy put into them with little or no gassing, but, when they are nearly charged, the electrical energy, instead of being "stored," shows itself in the form of more or less violent gassing, the amount depending upon the rate of charge. Gassing should not appear during discharge.

Efficiency.—It is always necessary to put more current into the battery on charge than is taken out on discharge, in order to bring it back to its original condition, the difference representing the loss in the battery and the ratio its efficiency.

While the efficiency varies under different conditions, the variation is not very great for anything like complete discharges, so that knowing what the efficiency is and the amount of discharge we can calculate approximately how much charge is required or how long the charge at any given rate. Under normal conditions, it is found that the charge should exceed the discharge by about 20 per cent.

Summing them up, we have four methods of checking the charge, namely: the rise in voltage, the rise in gravity, the gassing of the cells and the observed efficiency. For checking the discharge, we have the fall in specific gravity and voltage.

There are four points in the operation of a storage battery which must be looked out for, and if these are properly handled no trouble need be expected:

1. The battery must be charged properly.
2. The battery must not be discharged too long.
3. Short circuits between the plates must be prevented.
4. The plates must not be exposed to the air. They must be kept covered with electrolyte and only water of the proper purity used in replacing the evaporation.

Charge.—In the regular operation of a battery, the most important feature is the charging. Experience has shown that when charged too much the excessive gassing washes out the active material of the positive plates and thus decreases their capacity and life. On the other hand, undercharging results in sulphating, lack of capacity and, if carried to extremes, will result in a rapid disintegration of the plates. In order to meet both of these conditions, the best plan is to divide the charges into two types, regular charges and overcharges. Regular charges are simply intended to restore the capacity of a battery after discharge and are given on a very efficient basis, being discontinued, if anything, before the cells are quite full with the object of obviating harmful gassing and overcharging. Overcharges given at intervals of about two weeks are carried to a complete maximum for the purpose of evening up the cells, reducing all the sulphate and keeping the plates in good condition.

Where it is practical to obtain accurate specific gravity readings, these should be used in preference to either voltage, gassing or the efficiency for governing the charge but no matter which method is selected it is advisable where possible to occasionally use the others as a check.

Next to the gravity, the most reliable indication is the voltage. Its advantages have already been stated, namely: that the readings can be obtained at a distance from the battery and the voltage of a small cell can be read as accurately as that of a large.

*Extracts from paper read at the Atlantic City Convention of the International Association of Municipal Electricians, September 12, 13 and 14.

Digitized by Google

The greatest objection to the use of the voltage is that the reading is dependent upon the rate of current flowing, and where there is no current flowing, as on open circuit, the voltage readings are of no value whatever; thus voltage can only be used where the current rate is known.

Neither gassing nor efficiency should be considered where accurate charging is essential, as they cannot be depended upon for accurate result. Thus, they should only be used where the cells are very small or the conditions do not warrant the additional expense or labor required for accurate operation.

Gassing does not entail the use of any instruments, which is an advantage, but it does require access to the cells, so can only be used where the cells are within reach.

The efficiency method does not require access to the battery, but it does require an accurate knowledge of the amount of discharge, and this sometimes necessitates extra labor.

As most of you know, this is the method commonly employed in the case of fire alarm batteries. In this service the amount of discharge is constant and quite accurately known, so that no special readings are required in order to determine this. The cells are generally small, too small for accurate specific gravity readings. Their cost is so low that it would not pay to go to any great trouble or expense in order to get accurate operation, and the added life of the plates would probably not compensate for it. Thus, the efficiency method of charging has been selected as being the most suitable, because it is accurate enough for the purpose, the amount of discharge is accurately known, it is exceedingly simple and does not require special trips to the battery room in order to take observations.

Summing up the charge, we have two methods that can be used for careful operation, the gravity and voltage, and two methods which are applicable where less accurate operation is sufficient, gassing and the efficiency, and in each case the decision as to which shall be used depends upon whether the battery is accessible or not. Gravity and gassing require access to the cells; voltage and efficiency do not.

Discharge.—About the only point which has to be guarded against in connection with the discharge is not to discharge too far. To ascertain the amount of discharge or for determining when it should be stopped, the gravity and voltage only can be used, gassing and observed efficiency not being applicable. For indicating the amount of discharge at any given time, the specific gravity readings are the more valuable and, in fact, they constitute a fairly reliable ampere hour meter, the fall in gravity being independent of the discharge rate and almost directly proportional to the ampere hour discharge. It is the common practice in many classes of service to only discharge the cells to about one-half their capacity before charging, the remaining capacity being held in reserve for emergencies.

The voltmeter indicates the limit of the discharge very definitely, provided we know the discharging rate, but it is of comparatively little service in indicating the actual amount of discharge before the limit is reached.

Short Circuits.—For the prevention or detection of short circuits, a regular system of inspections and readings is required. At regular intervals the cells should all be looked over to see that the plates are uniform in color, and that no short circuits are forming, due to the plates shifting and getting together, to deposits lodging between the plates or to the sediment in the bottom of the jars getting up to the plates. Occasionally, when the cells first begin to gas, they should be inspected to see that they all begin to gas at the same time. If any are slow, this is an indication that these cells are falling behind and need attention.

Replacing the Evaporation and keeping the plates covered with electrolyte should be the simplest part of the operation, but for some reason it is one where a large percentage of the mistakes occur. There is a continual evaporation from a battery, and if this is not replaced the electrolyte gets below the tops of the plates. If they are allowed to remain exposed to the air any length of time, they lose their charge and are likely to be injured. As water alone evaporates from the electrolyte, pure water alone should be used for replacing it and not acid or electrolyte. For some reason, there is an idea abroad that the acid evaporates also and must be replaced, and a very great deal of trouble results from this. There is a very slight loss of acid due to other causes, but this is so slight that it only need be replaced ordinarily every couple of years and no trouble would probably result if it were entirely overlooked, as weak electrolyte is not likely to cause any trouble. On the other hand, too strong electrolyte resulting from the continual addition of acid is likely to injure or ruin the plates. The safest plan, therefore, is to use only water, unless acid is lost, as in the case of a broken jar. If you think acid is needed, write the manufacturer and get his advice before doing anything.

Conference on Rubber-Covered Wire.—A conference was held in New York City, August 9, between the Underwriters and the manufacturers of rubber-covered wire, who desired that inspection of rubber-covered wire made under the new National Electrical Code specifications should be conducted on a uniform basis throughout the country. The wire manufacturers insisted that they should have a voice as to the carrying out of the tests on rubber-covered wires. As a result of the conference, the inspection of wires will be undertaken entirely under the supervision of the Underwriters' Laboratories.

Any book on electrical application can be obtained of TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

Copper Clad Steel Wire in Overhead Fire and Police Service.*

BY WARREN E. FASTNACHT, CITY ELECTRICIAN, YORK, PA.

The prime requirement in a municipal fire alarm system is reliability of service at all times. Reliability is, therefore, a prime consideration and this means, in overhead work, that wires and cables must have ample tensile strength, with a reserve or margin to insure safety.

In the early days, soft drawn copper and iron were the only materials available in the form of wire, but the poor tensile strength of copper and the poor conductivity of iron made neither one an ideal material. It was recognized very soon that if the high conductivity of copper and the high tensile strength of steel could be combined in one wire, the result would be a perfect conductor for overhead lines. This led to many attempts to use bimetallic unwelded wires of copper and steel, with the numerous failures whose history is well known.

While these attempts were going on, hard drawn copper was discovered, and it seemed for a time that the problem was solved. Experience shows, however, that it was not solved, and we know today that there is a very large field for a wire of greater tensile strength. A few years ago I learned that a successful method of welding copper and steel had been discovered and I looked into it very thoroughly. This wire material is known as copper clad steel. We are satisfied after tests that it is far superior to any other wire manufactured for fire alarm and police service. We now have nine miles of No. 12 in use in York, on the fire and police systems, most of which was used to replace No. 10 B. & S. copper on lines which were the most affected by storms.

The cost of our change from No. 10 copper to No. 12 copper clad was very largely offset by the sale of the old No. 10 at its scrap value. The No. 12 copper clad is not as heavy and was installed with great ease and facility. It can be handled much more readily than copper, which is very likely to break at a small scratch or nick in the surface, while copper clad does not.

The table shows the tensile strength and resistance of copper and copper clad for No. 10, No. 12 and No. 14; also the weight per mile, for bare wire. Copper clad weighs about 7% less than copper, and is about 60% stronger and has 40% of the conductivity of copper in the regular grade.

	Weight per Mile		Breaking Weight		Resistance per Mile	
Size.	Copper.	Copper Clad.	Copper.	Copper Clad.	Copper.	Copper Clad.
No. 10.	.106	154	489	800	5.5	13.7
No. 12.	.104	97	307	510	8.7	21.8
No. 14.	. 66	61	193	330	13.9	34.9

In most signal systems the size of wire is based on its tensile strength only. For example, No. 10 copper is used for overhead lines, while No. 16 copper is ample for the same kind of service underground. The strength of No. 12 copper clad exceeds that of No. 10 copper by at least 4%, while its elastic limit is 50% greater. The resistance of No. 12 copper clad is about four times that of No. 10 copper, or about equal to No. 16, but our experience shows that the resistance factor is unimportant, in comparison with the gain in tensile properties and the reduction of cost. The higher elastic limit is an important advantage because the wire will not stretch under conditions which will cause considerable permanent increase in the sag of copper. This sort of thing reduces the life which copper ought to have, and would have if it possessed more strength. For this reason copper clad can safely be assumed to have a longer life than No. 10 copper, and much less annual maintenance cost, due to avoiding breaks and slack.

No. 12 copper clad will stay up in a storm longer than No. 10 copper for three reasons: First, it has more strength; second, it has a higher elastic limit; and lastly, it has a smaller diameter to catch wind and sleet. The extra battery cost is not significant in comparison with the many advantages which are secured.

In York we place our fire and police wires on 3-foot iron extension arms above all the pole tops, fastened with through bolts, which makes a rigid construction. This permits us to pull our wires up as taut as is safe to have them and where they are copper clad they remain that way. The box leads go down the poles in galvanized iron pipes, each equipped with an insulating joint before reaching the box. This practice reduces our chances for the occurrence of grounds. When police and fire alarm wires occupy the same pole, we use three and four-way extension arms. The saving in maintenance costs we find is an important item. We have not had a single break or case of trouble on our copper clad lines since they were installed. Last winter we had the most severe snow and sleet storms in years and No. 10 copper lines were down in all directions, but our No. 12 copper clad was not affected at all. After the sleet and snow melted, it became as taut as before.

The extra strength of copper clad also helps to hold up the pole line. The local telephone companies whose poles are used by the city appreciate the extra strength of copper clad and have advised us to this effect. The telephone companies themselves are also using the wire, and the York Telephone Company has had eighteen miles of No. 12 in service for several years without one case of line trouble.

*Abstracts from paper read at Atlantic City Convention of the International Association of Municipal Electricians, September 12, 13 and 14.

Mr. A. C. Terry, commercial superintendent, Western Union Telegraph Company, Pittsburgh, Pa., in renewing his subscription says: "Being a telegraph-telephone, or telephone-telegraph man, as you please, and as TELEGRAPH AND TELEPHONE AGE has broadened into a telegraph-telephone paper, I am more interested in its columns than ever before."

TELEGRAPH AND TELEPHONE AGE is the leading paper in these two fields and is progressive and newsy. Subscription price, $2.00 per year.

A Modern Police Signal System.*

BY J. W. KELLY, JR., CHIEF OF ELECTRICAL BUREAU, CAMDEN, N. J.

It is generally recognized that a reliable, rapid automatic recording and telegraphic signaling system is absolutely essential to secure full efficiency in police departments.

The best system is a combination of mechanical signals, telephones and flash lights. As our police signalling system in Camden is conceded by municipal electricians to be the latest and most up to date in the country, I will briefly describe it and give you some of the results derived from its use. The policemen report once every hour by pulling the mechanical signal in the street box. This is recorded automatically on a tape at headquarters, punching the box number and stamping the date, hour and minute the call is made. If headquarters do not need the officer for anything special, the whole force could report for an entire year without a word having been said. The operator on duty not only gets the report, but the officer knows that he is getting credit for his report by the bell in the street box tapping back in response to the register. If he does not get his tap back he knows that something is wrong with the signal circuit. He can then use the telephone in the street box. Taking the receiver off the hook brings up a red light on the switchboard in front of the operator ,and he then makes his report by telephone. If he cannot get the operator by telephone, he knows that both circuits are out of order and that he must use the ordinary exchange telephone service for his report. While the officer has the door of the box open, headquarters can get him by tapping the bell in the box, but the shutting of the door cuts out the box and the officer would be out of touch for an hour. Here is where the flashlight signals come into play. Distributed about the city at prominent points are red lamps suspended from twenty-two to twenty-five feet in the air. When an officer is needed these lights are turned on by the operator at headquarters and the officer at once calls up for instructions.

The street boxes are equipped with switching arrangements for sending in two duty calls as well as calls for wagon, ambulance, telephone, riot and fire. If the officer has a fighting prisoner, he can call the wagon without unlocking the box, by using his key in a special hole.

The headquarters equipment will receive report calls on eight different circuits at the same time without interference, and give proper credit in each case, distinguishing between duty calls and emergency calls. The duty calls come in without special alarm, but the instant an emergency call starts, a red light is shown and a bell rings calling the operator's attention. A glance at the tape shows what is needed before the box number starts to come in, so that he can signal either the wagon or ambulance to get out for a run. He then sets up the box number on the transmitter and starts it the instant the box number is completed, so that it is possible to have the order to the wagon or ambulance in five seconds from the time that the officer starts to pull the street box. The switchboard is equipped with the proper switches for calling the different stables, without interfering with each other, and similarly the stables can get headquarters without ringing the others.

What is perhaps the most important part of the up-to-date signalling system—the means of reaching the officer on his beat between the times that he is reporting—is the flash light signal. Our flash lights are arranged in circuits of five or more, so that when a circuit is turned on, no matter which way the officer may be walking, there is a lamp ahead of him. We can turn on any combination of circuits from one up to ten and burn them steadily or flash them according to any prearranged code. Some of the light stations are also equipped with bells, and these bells can be rung instead of the light flashed by reversing the current on the circuit. We find that the officers can see the lights quite easily in the daytime.

Some discussion has arisen relative to the best color to use for the flash lights. After experimenting with different colors we found that red was the best; blue lights will not show well at night, and if there are many trees, green cannot be used successfully. If the streets are clear of trees then green is as good as red. The red lights can be seen under all conditions where a light can be seen at all. Our lights are suspended from twenty-two to twenty-five feet in the air, most of them from goose necks fixed to a pole. Some of them are suspended in the centre of the intersecting streets. We use 25-candle power lamps in eight-inch red globes; the bells have double six-inch gongs and we use 110-volt current for both lamps and bells. We get the current from the nearest street lighting circuit, and pay ten cents per month for it. This amount has been fixed for all flash light work in the state of New Jersey.

The Dean system is a two-wire system. When the patrolman wishes to communicate with police headquarters he unlocks the patrol box and removes the receiver from its hook, thus calling headquarters for talking. When he wishes to make his duty call, he pulls down the hook projecting through the inner door. This action on his part sends impulses of current over one of the line wires to the police switchboard. The number of these impulses are so controlled by the box mechanism as to register the number of the box on an automatic ticker-tape controlled by apparatus upon the police switchboard. The telephone and registration circuits are non-interfering. Wagon calls can be sent in by pulling down the hook and pressing a button marked "Wagon."

In the combination boxes the fire key to the box is placed in a small recess covered with a glass plate, and located above the outer door. In case of fire, a citizen can break the glass, use the key to open the box and pull down the hook. The breaking of the glass connects the fire alarm circuit to the box mechanism. Pulling down the hook sends in the alarm to fire headquarters, and at the same time

*Extracts of paper read at the Convention of the International Association of Municipal Electricians, Atlantic City, N. J., September 12, 13 and 14.

Digitized by Google

registers it on the ticker tape at police headquarters. As soon as the glass is broken in turning in an alarm from the box the flashlight is turned on in that box and remains lighted until the key has been restored to its position and a new glass put in.

In the Dean system, the flash light is located in the patrol box; it has three lenses and shows a red light.

The Beginning of the Telegraph.

BY WALTER VAIL, OF DEPOSIT, N. Y.

In your issue for April 16 you published an article headed "The Beginning of the Telegraph," in which it was stated that Mr. H. M. Dellinger fitted up the first telegraph office in the world in Washington, D. C. The inference to be drawn from the article is so manifestly erroneous that I desire to submit a few facts regarding the matter.

The first telegraph line in operation was the Paddington and Drayton line in England in 1835, and was thirteen miles long. This antedated the Washington and Baltimore line by nine years.

On March 3, 1843, Congress appropriated $30,000 to build an experimental line between Washington and Baltimore. S. F. B. Morse was appointed superintendent of the construction and Alfred Vail superintendent of the machinery department. Morse's idea was to insulate the wires and put them in pipes, burying the pipes in the ground.

Ezra Cornell went to Baltimore and began, in October, 1843, laying the wires which had been prepared by Morse's assistant, Dr. Fisher. As each length was laid, Vail tested and united the conductors. Ten miles of the under-ground line had been laid when the insulation, which had been gradually failing, disappeared altogether.

In February, 1844, it was decided to place the conductors on poles. Vail and Cornell were employed in the basement of the Patent Office at Washington during March in joining the ends of the wires and making them ready for the poles. On April 1 the stringing of the wires was begun at Washington under the direction of Cornell. One set of apparatus was placed in the capitol and manipulated by Morse, while Vail transported the other set from place to place along the route of the line, and corresponded with Morse as occasion offered. On April 12 the wires were worked successfully for twelve miles. On April 23 Vail substituted the earth for part of the metallic circuit between Blandensburg and the capitol with satisfactory results. On April 30 the line was in operation between Annapolis Junction and Washington. On May 1 the Whig convention met at Baltimore, made its nominations and adjourned. When the train bearing the delegates arrived at Annapolis Junction, Vail went aboard the cars and got the news regarding the nominations at the convention. When Vail had any news to transmit to Morse he gave the signal "48." Morse at the capitol at Washington awaited this signal from Vail and was surrounded by a crowd of the curious who had been informed that great things might be expected to be shown by the telegraph. Suddenly the signal from Vail was heard, and Morse, all excitement and eagerness, bent forward to decipher the characters that appeared embossed upon the little strip of paper as it came from the register. The message at last completed he rose and said: "Gentlemen, the convention has adjourned. The train from Baltimore, bearing that information, has just left Annapolis Junction, and Mr. Vail has telegraphed me the ticket nominated, and it is,"—here he hesitated, holding in his hand the proof of victory of science over space—"it is Clay and Frelinghuysen!"

The work went steadily forward. On May 23 the wires reached the Mount Clare depot in Baltimore and the instruments were set up and operated with gratifying success through forty miles of line. In the afternoon of May 24 the instruments were transferred to the lower depot in Baltimore, in readiness for the regular operation of the line.

These two instruments used by Vail and Morse on this first telegraph line built in the United States were made by a Mr. Stokell from working drawings made by Alfred Vail. They embodied for the first time the beautiful mechanical conception of recording by the indentation of a steel embossing point upon the paper, working in combination with a grooved roller. One of the instruments was used by Morse at the capitol in Washington, the other was used by Vail along the line. Each of these instruments when ready for service weighed 185 pounds. Vail retained the one he used, and before he died bequeathed it to his oldest son, Stephen Vail. It was loaned to and was at the Smithsonian Institute at Washington for many years. It was removed by Vail several years ago, and was finally sold to Hiram W. Sibley, of Rochester, N. Y., who placed it in the Sibley electrical department of Cornell University at Ithaca, N. Y., for safe keeping.

The evidence is conclusive that Mr. Dellinger did not fit up the first telegraph office in the world, because the Paddington and Drayton line in England had two or more offices, also that when the instruments were transferred from the Mount Clare depot and set up at the lower depot in Baltimore, the office was fitted up for the regular business of the line.

Mr. Arthur Walsh, an old time and military telegrapher now of Van Nuys, Cal., in renewing his subscription, says: "You may consider me a life subscriber to your excellent paper. It is with great regret, however, that I read of the numerous deaths among my military telegraph comrades. We are all old men now and, in the nature of things, we cannot hope to live many years more." Mr. Walsh was born in Dublin, Ireland, in 1846, and entered the telegraph service at Cleveland, Ohio, in March, 1862. He did service in the Army in Kentucky and in the Army of the Cumberland under Colonel J. C. Van Duzer during the Civil War.

ANSWERS TO QUESTIONS.

[In this department questions on matters of a practical character, and of general interest, will be answered. Questions intended for this department must be signed by the writer's full name—not for publication, but for identity. No attention will be paid to anonymous communications.]

(70) Q. Will you please answer the following questions in regard to the new Postal switchboard described and illustrated in your issue for September 16? C. H. M.

(1) What signaling apparatus is used on the annunciator board? (2) How many wires are provided for in each section? (3) What means are adopted to arrest accidental foreign heavy currents before they reach the instruments? (4) In what respect does the construction of the new board resemble that required for high tension wires? (5) Please explain the functions of the terminal and cross-connecting frames. (6) Is it because slate is a better insulator than wood that it is used in switchboard construction? (7) Could not pin jacks be substituted for the ordinary wedge and spring jack? (8) Explain the system of transfers used in intercommunication between the various sections of the board. (9) Suppose it is desired to connect a wire on the eastern board with one on the southern board, how is it done? Are the connections like those on a telephone multiple board? (10) Is there any particular reason why brass should be used for switchboard work in preference to copper, which I believe has greater conductivity?

A. 1—The type of signaling device used in connection with the annunciator board consists of an interchangeable bell or lamp signal operated by differentially wound magnets. These magnets control shutters or drops, bearing numbers which when operated indicate to the annunciator board attendant what office desires his attention. The main circuits of the annunicators are in series with closed circuit pin-jacks. To operate the annunciator at the main office, the branch office operator "grounds" the loop by means of a switch, this action cuts out one winding of the differential annunciator and allows the magnet to become energized due to the current in the companion winding, thus releasing the shutter bearing the number of the office calling. 2—Fifty main line wires. 3—One-half ampere fuses mounted on terminal frames. 4—In that the iron, slate and other material used in its construction is inflammable. 5—The function of the terminal frame is to act as an intermediate connection between the main line wires where they enter the building, and the switchboard in the operating room. The terminal room equipment is in reality a switching system, practically a duplicate of that installed in the main operating room, but constructed with the object of providing for flexibility and utility rather than for fine appearance. The many advantages of having a complete switching system close to the point where lines enter the building from underground and aerial cables, are obvious. The function of the cross-connecting frame is to act as an intermediate connection between the pin-jack and spring-jack connections of the switchboards, and the instruments located on operating tables. 6—Not directly but better insulation is secured by using mica bushings. The slate is non-inflammable and non-shrinkable and thus permanently retains the alignment of the parts mounted upon it which is not the case with wooden boards. 7—They could be, and the Postal engineers have utilized thousands of such jacks in place of spring-jacks as formerly employed in telegraph switching. It has, however, been found that the spring-jack which permits the insertion of several wedges in various relations to each other meets main-line telegraph switchboard requirements better than the pin-jacks. With four wedges involved, eight pin-jacks would be needed to make all the combinations that can be made with one spring-jack. 8—Pin-jacks properly marked are mounted on each section of the board and are connected with similar pin-jacks in each of the other sections. That is, each section has several possible direct connections with each other section of the entire board. 9—To operate the transfers the attendant uses a single cord equipped with a wedge at one end and a plug at the other end, the wedge is inserted in the spring-jack of the wire to be transferred while the plug end is inserted in one of the pin-jacks leading to the section to which the wire is to be transferred. At the distant section the wire is picked up through the pin-jack bearing the corresponding number. 10—On account of the comparatively large dimensions of the metal parts employed in switchboard construction, the question of the relative conductivity of brass as compared with copper is unimportant. From a mechanical standpoint brass is superior to copper as it can be worked to better advantage and it wears much better.

Memorial to Volta.—Signor Calissano, Italian Minister of Posts and Telegraphs, accompanied by telegraphists who had assembled at Como from all parts of the world, on September 1 visited the grave of Alessandro Volta, the inventor of the electric battery, at Camnago. The minister and delegates placed wreaths on the tomb, and speeches were made by Signor Calissano, Signor Battelli, a member of the Italian Chamber, M. Buels, director of the Belgian Telegraphs, and Signor Pietro Volta, a nephew of the inventor. A memorial stone was unveiled bearing an inscription recording the esteem in which Volta is held.

Cupid and Mercury.—A 63-year old Western Union Telegraph messenger in Kansas City, Mo., was married recently.

The Railroad.

Mr. Fred Kuehn of the telegraph department of the Lake Shore and Michigan Southern Railroad Company, Cleveland, Ohio, was a recent New York visitor. He was accompanied by his wife.

Change of Headquarters.—The headquarters of Mr. C. W. L. Mickley, superintendent of telegraph, International and Great Northern Railroad Company, have been removed from Palestine to Houston, Tex.

Telephone Dispatching on Rock Island.—The Chicago, Rock Island and Pacific Railway will equip its Kansas division with forty-two Western Electric selectors for telephone train dispatching. The new circuit will run from Caldwood to Belleville, Kan., a distance of 210 miles. The dispatcher will be located in the middle of the line at Herrington, Kan.

Proceedings of Convention of Railway Telegraph Superintendents.—The proceedings of the annual meeting of the Association of Railway Telegraph Superintendents, held at Boston, Mass., June 26, 27 and 28, have been issued in the usual form. The rapid growth of the work of the association is indicated by the fact that the bound volume contains 331 pages. The work was produced under the immediate supervision of Secretary P. W. Drew.

Meeting of Railway Telegraph Superintendents.—Owing to the unavoidable delay in issuing the proceedings of the annual convention of the Association of Railway Telegraph Superintendents at Boston in June, it has been decided to omit the usual September meeting of the Western Division of that association. Plans are under way to hold a joint meeting of the Eastern and Western Divisions in Chicago on November 23 and 24. Members desiring to introduce any subject for discussion at that time should communicate with Mr. E. A. Chenery, superintendent of telegraph of the Missouri Pacific Railway, St. Louis, Mo., who is chairman of the Western Division.

Railway Telephone Train Dispatching.

The Chicago, Milwaukee and St. Paul Railway Company has ordered of the Western Electric Company seventy-five telephone selectors for use on its Hastings and Dakota division. Three circuits will be installed, the total mileage being about 390 miles. No. 9 B. & S. copper will be used on all three circuits.

The Atlantic Coast Line has placed an order with the Western Electric Company for ninety station telephone train dispatching outfits, which will be used to equip 235 miles of track. A train, a message and a block circuit will be installed between Savannah, Ga., and Jacksonville, Fla., with a branch from Jesup to Waycross, Ga., and from there back to Folkstone, Ga., where it will meet the main line. The train dispatcher will be located at Savannah.

The Turner Monument Fund.

We give herewith a view of the bronze tablet that is to be set on the face of the monument to be erected at Harriman, N. Y., (formerly Turner) and unveiled in November, to commemorate the sending of the first telegraphic train order.

The tablet was designed by Mr. Charles Keck, of New York, the well-known sculptor, and, as will be seen, is a handsome and artistic piece of work. It is six feet high by three feet, three inches wide, and is composed of United States standard bronze.

VIEW OF BRONZE TABLET FOR TURNER MONUMENT.

It will be cast by the Gorham Company, and will be ready about the first week in November.

The vignette of Mr. Charles Minot, at the head of the tablet, is a faithful likeness of the subject and is artistically executed.

The design of the tablet as a whole is both artistic and emblematic of the telegraph. The source of electric current and the means of utilizing it are faithfully represented, and the historical message, the sending of which is to be commemorated by the

Digitized by Google

monument, is shown in embossed characters on the tape delivered by the old-time Morse register.

The stone monument will be furnished by Mrs. E. H. Harriman, of Arden, N. Y., at her own expense, and is being cut and erected under the supervision of Mr. C. T. Ford, of Central Valley, N. Y., superintendent of the Harriman estate.

The committee is at work on the plans for the dedicatory exercises. Mr. Henry D. Estabrook, of New York, has been chosen to make the address at the unveiling, and, as was announced in these columns September 16, Miss Gertrude M. Griffith, daughter of Mr. E. P. Griffith, chairman of the Monument Fund, has been unanimously selected to unveil the monument.

The ceremony will take place about the middle of November, and it is expected that a large and representative party will be present to do honor to the memory of Mr. Minot and his historic achievement.

The Fund committee desires it to be understood that those who wish to contribute toward the fund have yet an opportunity to do so. Mr. J. B. Taltavall, TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York, is the treasurer, and all contributions are acknowledged in these columns.

The contributions received up to date are as follows: Previously acknowledged, $1,672.49; W. L. Ives, New York, $1.00; F. J. Hickey, New York, $1.00; F. J. McKenna, Pittsburgh, Pa., $1.00. Total, $1,675.49.

Telephone Pioneers of America.

A new list of members of the association of Telephone Pioneers of America will be issued about October 1. With it will be mailed a beautiful badge adopted for the Boston meeting on November 2, 3 and 4. The name of each member receiving a badge will be printed across the face of the ribbon in gold letters. These badges will be in the nature of souvenirs of this, the organization meeting of the association.

Mr. Frank W. Harrington, a well-known old time electrical man, helped in the work of manufacturing the original Bell instruments in Boston in 1871, and he has applied for admission to membership.

The association now has over 400 members, including eleven women, who entered the service in 1882 and 1883. The list of members at the present time shows three who began in 1875 and twenty-five in 1877. The maximum number registered in any one year is 48, which was in 1879.

It is proposed to request all members to bring to the Boston convention any matter of an interesting character for the exhibition, for which proper provision will be made.

Mr. Theo. N. Vail, president of the American Telephone and Telegraph Company, is taking an active interest in the association, and Mr. Angus S. Hibbard, of his personal staff, is in charge of the details for the entertainment at Boston.

The Press Committee consists of Mr. Henry McDonald, of the American Telephone and Telegraph Company, and Mr. J. H. Barry, of the New England Telephone and Telegraph Company, Boston, Mass.

The committee of arrangements is composed of Messrs. Henry W. Pope, Charles R. Truex and Thomas B. Doolittle, 15 Dey Street, New York.

Radio-Telegraphy.

Marconi Wireless in Canada.—At the annual meeting of the Marconi Wireless Telegraph Company of Canada, at Montreal, on October 5, the stockholders will be asked to approve the creation and issue of $2,500,000 30-year first mortgage six per cent gold bonds, for the purpose of placing the finances of the company on a sound basis.

Large Wireless Towers in Washington.—What is said will be the largest wireless towers in the world are to be erected at Washington, D. C., for the Navy Department. There will be three of them and they will be known as the Arlington towers. They will be 600 feet high. The range of the station will be fully 3,000 miles, and it is expected to have it completed next March.

Examination for Wireless Operator.—The United States Civil Service Commission, Washington, D. C., announces an examination on October 4, at various cities throughout the country, to secure eligibles from which to make certification to fill a vacancy in the position of electrician and wireless telegraph operator at a salary of $900 per annum, for duty in the lighthouse service in the Territory of Hawaii, and vacancies requiring similar qualifications as they may occur. As considerable difficulty has been experienced in securing eligibles for the position mentioned, qualified persons are urged to enter this examination. Applicants should apply to the United States Civil Service Commission, Washington, D. C.

Death of Paul Hoenack.

Paul Hoenack, probably the most expert and experienced mechanician in the manufacture of telegraph apparatus in this country, died at his home in New York City August 4 of heart failure. Mr. Hoenack was born at Soma, Prussian Germany, in 1840. He learned and worked at his trade in Siemen Halske's works in Berlin; thence he went to England, where for some years he was in the employ of Elliott Brothers, coming to America in 1865 and entering the service of the Western Union Telegraph Company under the personal supervision of Mr. Phelps, inventor of the Phelps "combination" printing instrument. In 1878 Mr. Hoenack established a small shop of his own. His first work was on the McDonough telephone and various experimental modifications for demonstration before the courts in the protracted litigation with the Bell Company. Among his patrons were many of the most prominent inventors in electricity. Mr. Hoenack's work covered the entire field of cable, synchronous, multiplex, stock quotation, printing and rapid automatic telegraphy. Throughout his long business career he was trusted and respected by those whose secrets were fashioned in his shop.

originated and developed Selective Calling systems.

It has set the standard—others imitate.

Its sole business is Telephone and Telegraph Equipment for Railway Service.

New York **Chicago**

New Book on Telephony.

A new book entitled "Modern American Telephony in All Its Branches," by Arthur Bessey Smith, will be ready for delivery in September. It will contain over 800 pages and nearly 600 illustrations, and will be the most complete and up-to-date work on the subject. The price will be $2.00 per copy. Address TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

Telephonology

The New Telephone Book

Contains 16 chapters covering every branch of telephony.

Comprises 586 pages full of valuable information for every one interested in the telephone.

Has 700 illustrations of up-to-date apparatus and circuits.

Written for the practical telephone man, who has no time to study theory, but who is looking for practical instruction "how to do" things.

Tells how to locate and remedy trouble, line, instrument and switchboard.

How to make simple testing equipment and to use it.

All modern systems—both Magneto and Common Battery described and illustrated.

The whole subject is thoroughly covered, from the theory of magnetism to automatic and wireless telephony, including composite, harmonic and selective lockout systems.

PRINTED FROM A NEW SET OF PLATES

THE MOST SUCCESSFUL ELEMENTARY WORK.

A B C OF ELECTRICITY

By WM. H. MEADOWCROFT

One volume, 12mo. cloth, 50 cents. Fully Illustrated.

This excellent primary book has taken the first place in elementary scientific works. It has received the endorsement of Thos. A. Edison. It is for every person desiring a knowledge of electricity, and is written in simple style, so that a child can understand the work. It is what its title implies, the first flight of steps in electricity.

ENTHUSIASTICALLY ENDORSED BY THE PRESS.

Sent postpaid on receipt of price by J. B. TALTAVALL, Telegraph and Telephone Age.
253 BROADWAY, NEW YORK.

HOMAN'S A.B.C. of the TELEPHONE

A Practical Treatise.
WITH ILLUSTRATIONS AND DIAGRAMS.

"It is surprising what an excellent book can be produced at such a low price. Many of the illustrations are excellent, and the diagrams are exceedingly clear. The theory of the subject is described and the practical details are given. * * * Typographically the book is a satisfactory one, and the binding, black with yellow type, is very effective."—The Scientific American.

"This book belongs with the best class of popular scientific literature. While it is strictly elementary, in the sense that it begins with the elements, it nevertheless gives a very comprehensive survey of the entire field of telephone apparatus and construction. * * * In order that the book may be fully comprehended by the beginner the discussion of the telephone proper is preceded by an admirable chapter on the theory of sound and another on the fundamental principles of electricity. While not a 'primer,' the book is thus one which anyone can read if he has enough interest in the subject to try."—American Machinist.

The volume contains 375 pages, 268 illustrations and diagrams; it is handsomely bound in black vellum cloth, and is a generously good book.

Price $1.00

Testing Apparatus. — Foote, Pierson & Co., New York, makers of electrical measuring and testing instruments, have put upon the market an improved portable switch testing set, which is stated to be easy to use and accurate within one-tenth of one per cent. It is recommended for telegraph and telephone service and is a very compact piece of apparatus. See their advertisement on the last page of the cover.

Telephone Train Dispatching in Hudson Tunnels.—The Pennsylvania Railroad Company has recently ordered fourteen standard Western Electric selectors for use in its Hudson tunnels, New York. The section equipped is nine miles in length. In addition to these selectors, fourteen special six-line test boards have been ordered. There will also be thirteen ten-line jack boxes, which will be used for blocking purposes.

Selector Equipment for the Atchison.—The Atchison, Topeka & Santa Fe Railway has had over 500 Gill selectors in use in its telephone train dispatching circuits for several years past. This company is extending its telephone dispatching system and has placed an order with the United States Electric Company of New York for fifty-five Gill selector equipments of the local battery bell type, with dispatchers' calling outfits for the new circuits.

Meeting of Western Union Managers.

The managers of the seventh district of the Western Division of the Western Union Telegraph Company held a meeting at the Gibson House, Cincinnati, Ohio, September 8 and 9. District commercial superintendent I. N. Miller, of Cincinnati, delivered the opening address. Other addresses were made as follows: "Moving Business," by A. A. Montgomery, district traffic superintendent, Cincinnati; "Courtesy," by F. H. Wolfe, manager Shelbyville, Ind.; "Quick and Correct Service the Best Solicitor," by E. H. Cost, manager, Xenia, Ohio; "Soliciting Business"—dialogue, by Messrs. R. C. Bliss and W. W. Browne, managers of the Cincinnati and Dayton, Ohio, offices respectively; "Messengers—How to Secure Them," by E. D. Keyes, manager, Hamilton, Ohio; "The Relations of the Telegraph to the Newspaper," by L. R. Scholl, Cincinnati, Ohio; "The New Features and Creating New Business," by S. M. Dunlap, manager, Columbus, Ohio. Other topics discussed were: Is the Telegraph Popular?, Breaking the Ice, Forms 219, 219a, Attended Pay Stations, Claims of Telephone Company Collecting Western Union Bills, Condition of Offices Handling More Business by Telephone, Condition of Instruments, Joint Offices with Bell Companies, Labor Laws, Class "A" Offices, Errors and Causes, Timing Messages, Signs, Miscellaneous.

A banquet was held at the Gibson House in the evening of September 8, after which the party reviewed the parade in celebration of the Fern Bank Dam across the Ohio River a few miles below the city. The afternoon and evening of September 9 were spent in sightseeing.

Those present were: M. T. Cook, division commercial superintendent, and R. W. Whitehead, division plant superintendent, Chicago, Ill.; E. Parsons, district plant superintendent, Indianapolis, Ind.; A. A. Montgomery, district traffic superintendent, Cincinnati, Ohio; A. R. McGrath, commercial agent, Chicago, Ill., and the following managers: G. C. Lemon, Athens, Ohio; Miss Clara Frazer, Aurora, Ind.; S. M. Dunlap, Columbus, Ohio; R. C. Bliss, Cincinnati, Ohio; G. B. Schaeffer, Chillicothe, Ohio; Miss A. B. Sprague, Connersville, Ind.; W. W. Browne, Dayton, Ohio; I. E. Ward, Findlay, Ohio; C. E. Eckert, Greenfield, Ohio; E. D. Keyes, Hamilton, Ohio; C. Waidelich, Lancaster, Ohio; G. E. Balsley, Lawrenceburg, Ind.; H. L. Clark, Marietta, Ohio; J. S. Todd, Middletown, Ohio; R. L. Rhodes, Newark, Ohio; G. R. Lockwood, Portsmouth, Ohio; F. H. Wolfe, Shelbyville, Ind.; T. E. Jones, Springfield, Ohio; R. R. Miller, Troy, Ohio; J. R. Clark, Vincennes, Ind.; E. H. Cost, Xenia, Ohio; C. E. Jones, Zanesville, Ohio. Among others present were: L. R. Scholl, H. H. Driehaus, F. O. Miller and Miss A. L. Madden, all of Cincinnati.

LETTERS FROM OUR AGENTS.

PHILADELPHIA, WESTERN UNION.

Mr. C. B. Wood, in charge of the messenger boys in this office, and who was one of the most indefatigable workers to make the Old Timers' reunion at Atlantic City a success, has been seriously ill at his home in Palmyra ever since the convention. He is suffering from a general breakdown from overwork.

Mr. W. C. Shugar, night chief; Mr. J. V. Burger, wire chief, and Messrs. J. T. Wilde, E. V. McElroy, E. Truitt and John Truitt, traffic chiefs, have returned from their vacations.

Mr. E. A. Dos Sandos, all-night chief, is now on his vacation. Mr. E. L. Maize, assistant wire chief, spent a very pleasant holiday at Atlantic City during the Old Timers' reunion.

John Roddy, aged 40 years, who was connected with the Western Union service in this city for twenty-nine years, died suddenly recently.

Among recent marriages here were Mr. Conrad Walter of the Easton, Pa., office, to Miss Mary Long of this office, and Mr. R. J. Waddams of the Atlantic City office to Miss Mary A. Fitzgerald of this office.

Mr. Edward J. Smith, who has been claim agent for some time past, has been promoted to the assistant managership of this office.

RICHMOND, VA., WESTERN UNION.

During the Beattie murder trial at Chesterfield courthouse which lasted from August 21 until September 8, this company handled some 960,000 words of press matter. The large newspapers of the East and the press associations had special

Digitized by Google

representatives on the ground to the number of about thirty, and in order to handle their matter eight wires were strung along the country road between Centralia and the courthouse and an office was opened in a store building about one hundred feet from the courthouse proper. All of the press matter was handled from this office except on the last day of the trial when an instrument was installed in the courtroom so that the jury's verdict could be flashed to the outside world the moment it was rendered. The arrangements throughout were necessarily crude, but it is a notable fact that the correspondents had naught but words of commendation for the service that was given them. The jury's verdict of "guilty" was in the offices of newspapers a thousand miles away as soon as the words were uttered. The clatter of telegraph instruments caused much astonishment on the part of the natives of the peaceful little country village and it is doubtful if Chesterfield will ever again be the scene of so much bustle and activity. The correspondents and their interests at the trial were looked after by district manager J. S. C. Murphy and the operators and circuits were under the supervision of chief operator F. R. Veale of Richmond. The following operators from Richmond were assigned to duty at Chesterfield: C. M. Rosson, F. A. Browning, S. S. Hart, H. L. Hudson, B. B. Lytton, L. R. Sexton and O. H. Peacock.

Meetings of the electrical class were discontinued during the Beattie trial and will not be resumed until cool weather.

OKLAHOMA CITY, WESTERN UNION.

Manager H. G. Robinson has returned from Colorado.

Mr. H. K. Pottenger, formerly of the "Frisco" at Sapulpa, Okla., has been appointed day wire chief and Mr. J. F. Slack night wire chief.

Among the late arrivals are, Mrs. E. E. Tracey from St. Louis, Mo., Mr. C. M. Laurendine from Mobile, Ala., and Mr. W. L. Germany from Dallas, Tex.

The personnel of this office at present is: Mr. H. G. Robinson, manager; Messrs. E. E. Lash, chief, days; G. C. Moeser, day traffic chief; H. K. Pottenger, day wire chief; R. N. Long, night chief; J. F. Slack, night wire chief, and L. J. Tucker, all-night chief.

This office is equipped with a full dynamo plant using three potentials and a pair of local machines. Six quadruplex sets are employed and some Atheam quadruplexes are to be installed soon. A system of loops to the *Oklahoman* office is maintained. Mr. M. C. Harper is manager at the *Oklahoman* office.

The great telegraphic song hit, "SEND ME A NIGHT LETTER, DEARIE." Good, catchy music; beautiful title design magnificently printed in colors. Title contains night letter. Sung all over New York, 17c. by mail. All popular music sent by mail.

B. L. BRANNAN,
195 B'way, N. Y.

The closing of the night offices in this district is causing considerable overtime in the early morning occasioned by an overflow of night letters. All telephoning is done from this office for the entire state.

Mr. Votaw of this office was one of the musicians who took a prominent part in the recent annual reunion of the Spanish-American War Veterans in this city.

GAINESVILLE, TEX., MACKAY.

The force of the Mackay Telegraph and Cable Company at Gainesville, besides manager W. Dalton, consists of Mr. Arthur Parte, operator; W. Henderson and Arthur Allagood, messengers.

T. M. B. A. Assessment.—Assessments Nos. 529 and 530 have been levied by the Telegraphers' Mutual Benefit Association to meet the claims arising from the deaths of Ellis H. Holroyd at Chicago, Ill., William O'Niel at Belvidere, N. J., Morton W. Courtright at Chicago, Ill., Robert Stimus at Moorestown, N. J., Edgar H. Brown at Chicago, Ill., Frank B. Williams at Louisville, Ky., Edwin Butler at New York, John E. Tyrrell at Jackson, Mich., Anthony F. Saunders at Kansas City, Mo., Christopher Reilly at Memphis, Tenn., Walter D. Francis at East Orange, N. J., Henry Griffith at State Sanitarium, Md.

The Telegraphers' Mutual Benefit Association, 195 Broadway, New York, has for nearly half a century proclaimed the absolute necessity of life insurance and provided a safe and economical form of protection for the home and family within the means of every telegraph and telephone employe. A certificate of membership affording protection of $500 or $1,000, or both, is easily obtainable by every one in good health engaged in telegraph or telephone service, either commercial or railroad, between the ages of 18 and 45, and should be held by all employes not otherwise provided with adequate life protection.

Martin's double or single lever **VIBROPLEX** $7.50. D. C. DeLany, 15 S. Broad St., Atlanta, Ga.

TRANSMITTING MACHINES

I am placing on the market improved YETMAN TRANSMITTING TYPEWRITERS, and KEYBOARD TRANSMITTERS without typewriting features. Am prepared to exchange, repair or rebuild all old machines. Write for catalogues and particulars to

James Uncles, NORTH ADAMS Massachusetts

Rubber Telegraph Key Knobs.

No operator who has had to use a hard key knob continuously should fail to possess one of these flexible rubber key caps, which fits snugly over the hard rubber key knob, forming an air cushion. They render the touch smooth and the manipulation of the key much easier. Price, fifteen cents.

SOME POINTS ON ELECTRICITY.

BY WILLIS H. JONES.

Loop, Cord, Wedge and Jack Troubles—A Hint to Linemen.

PART I.

One would naturally suppose that because branch office loops are short compared with the lengths of main line conductors, the number of "openings" and other interruptions to their operation from which we suffer almost daily, should be diminished in like proportion. As a matter of fact, however, notwithstanding the conductors of such loops are mainly underground circuits and therefore not liable to be broken, the reverse of this order obtains.

Another thing a layman would hardly suspect is that probably 80 per cent of all the interruptions to loop operation occur on grounded or duplex loops; that is to say, loops connected with multiplex circuits.

Single line loops seem to be comparatively free from interruptions, although in many instances they parallel the duplex loops that bother us in the same cable and are placed in the same branch office switchboard.

The explanation is that, although the single line loops may be subjected to many of the identical trouble-contributing influences which are fatal to the operation of duplex loops, the higher E. M. F.'s provided to furnish current for the former are able to break down and thus override many of the situations which the lower pressures of local batteries are not able to cope with.

This fact certainly presents the strongest kind of an argument in favor of employing higher E. M. F.'s, on multiplex loop local circuits, and the idea becomes still stronger as we note the number of peculiar sources of little troubles the average lineman finds almost impossible to locate.

SPRINGJACK DEFECTS.

As "loop trouble" embraces all the defects of the apparatus and paraphernalia with which the conductors proper are connected, we will discuss them separately, beginning with the springjacks in the switchboard.

Now a springjack, as everyone knows, is about as strong and substantial a piece of apparatus as one could desire, and for that reason is often unsuspected as a source of trouble, which may exist for a long time before suspicion is finally directed to it.

If the lineman finds the tension spring normal and wire connections good, as he usually does, he reports "no trouble there," and returns without having accomplished anything, but under the impression that he was given a wrong clue. In the meantime the loop interruptions continue at frequent intervals daily.

The particular defect we wish to call attention to, and which the linemen cannot see, and therefore do not suspect, is a rusty or worn hingepin, and when this happens there is but one remedy, viz., remove the jack bodily from the board, take out the pin and replace it with a new one that is bright and clean. In nearly every case where this method is followed the trouble will cease at once.

This defect should always be suspected where loops close simultaneously with the insertion of the branch office test set at the switchboard or by otherwise altering the position of the wedge.

Of course a loop may open temporarily owing to the presence of a particle of dust having settled between the lips and edge of the wedge, which by the insertion of the test wedge may have been removed. For this and other reasons a defective pin is usually not suspected, especially when one finds it impossible to reopen the circuit by altering the position of the wedge for the purpose of locating the fault. But do not be deceived; remember the old saying, "a watched pot never boils." Your remedy is this—when these loop openings have occurred daily for sometime, while all the connections appear normal, yet the line closes when you cut in at the board, remove the jack at once and overhaul it.

Recent experience with defective loops has demonstrated conclusively the fact that nearly all old or much used switchboards contain one or more springjacks that cause trouble daily in the manner described and linemen should attach more impor-

Digitized by Google

tance to the contention that frequent overhauling of the jacks should be the rule instead of the exception.

LOOSE CONNECTIONS.

Another quite common defect in a springjack is the opening of a duplex loop on the receiving side. This is usually caused by the nut which holds the wire fast to the brass plate, or under lip of the jack, becoming loosened. This should be the first point examined when seeking the source of the trouble. It is caused by the hammering of the upper lip on the brass plate beneath whenever a wedge is suddenly withdrawn. In the course of time the nut becomes loosened, especially after the wood warps, and the receiving side loop conductor makes an imperfect contact with the under lip. It is obvious, therefore, that these small nuts should be examined regularly at frequent intervals, instead of waiting until the loop opens.

The sending side, or upper lip connection, is not so likely to work loose, as a much stronger means is used for connecting the conductor, yet it should receive proper inspection now and then.

(To be continued.)

Recent Telegraph and Telephone Patents.

ISSUED SEPTEMBER 19.

1,003,476. Telephone System. To A. D. T. Libby, Elyria, Ohio.

ISSUED SEPTEMBER 26.

1,004,038. Printing Telegraph. To C. L. Krum, Chicago, Ill.

1,004,290. Telephone system. To C. W. McKibben, Beaumont, Tex.

Personal.

Mr. E. A. Chenery, superintendent of telegraph, Missouri Pacific Railroad, St. Louis, Mo., was a recent New York visitor.

Dr. K. G. Frank, American representative of the Siemens & Halske Electrical Works, Berlin, Germany, has returned to New York after an absence of several months in Europe.

Mr. Norman Harrison chief engineer of the General Post Office, Johannesburg, South Africa, is in the United States on a trip of inspection of the telegraph and telephone systems, and is at present in New York.

Mr. Frank B. Knight special agent in charge of publicity, Southwestern Telephone and Telegraph Company, Dallas, Tex., and an old-time telegrapher, arrived from Europe on October 10 after an absence of several months.

Dr. Adolph Franke and Dr. Eberling, of the Siemens & Halske Electrical Works, Berlin, Germany, have arrived in New York and will spend a few weeks inspecting telegraph, telephone and other electrical interests in this country.

Mr. Francis W. Jones and Mrs. Jones, of Central Valley, N. Y., have gone to West Palm Beach, Fla., to spend the winter. They were accompanied by Miss Alice Le Bel, of Quebec, Canada. Mr. Jones was formerly electrical engineer of the Postal Telegraph-Cable Company, New York.

Colonel Robert C. Clowry and party returned from Europe on October 3, having been absent ten weeks. They motored through England, France, Switzerland, Austria and Germany. The roads were in splendid condition and the hotel accommodations excellent. The Colonel met a great many old friends from America on his tour, including Mr. Thomas A. Edison, with whom he had a jolly meeting in Paris and Berlin.

Postal Telegraph-Cable Company.

EXECUTIVE OFFICES.

Mr. C. C. Adams, second vice-president of this company, has returned from a trip of several weeks in Europe.

Mr. D. McNicol, of the electrical engineer's office, New York, is in Chicago on business connected with the engineering department of the company.

Mr. W. C. Lloyd, manager at New Orleans, La., has been advanced to be superintendent of the third district, of the Southern Division, with headquarters at Atlanta, Ga., vice C. B. Arrington, resigned.

Mr. Nelson E. Church, formerly manager of the Western Union Telegraph Company at Pittsburgh, Pa., has been appointed manager of the New Orleans, La., office of this company, to succeed Mr. W. C. Lloyd.

Mr. C. M. Baker, division general superintendent of plant at Chicago, is seriously ill at Galveston, Tex.

Mr. C. C. Ramsay, manager of the Portland, Me., office of this company and Mr. P. J. Farrel, quadruplex chief of the Boston office, were recent executive office visitors.

Manager W. C. Lloyd Advanced to a Superintendency.

Mr. W. C. Lloyd, superintendent of the third district, Southern Division, of the Postal Telegraph-Cable Company, with headquarters at Atlanta, Ga., is a native of Alabama, being born at Bladen Springs, Ala., August 15, 1872.

At sixteen years of age young Lloyd began life as a messenger at Waynesboro, Miss. Acquiring the ability to telegraph, he found employment for a number of years in the railroad service at various points in the South. His first engagement in the commercial service as an operator was with the Western Union Telegraph Company at Eufaula, Ala., and afterwards at Atlanta, Ga. In 1896 he went with the United Press at Columbus, Ga., but the failure of that concern in the year following resulted in Mr. Lloyd's becoming identified with the Postal at Birmingham, Ala., in the employ of which company he has since remained, his career therein being marked with steady advancement. From the position of operator, he was promoted to be chief operator at Vicksburg, Miss., thence being

Digitized by Google

transferred to the Memphis office as all-night chief. Then he was sent back to Birmingham to fill the position of night chief, but was soon returned to Memphis as chief operator. A year later he was promoted to the managership at Memphis in which position he remained for two years. In June, 1908, Mr. Lloyd was appointed manager of the New Orleans office which position he held at the time of his recent appointment as superintendent at Atlanta.

W. C. LLOYD,
Superintendent Third District, Atlanta, Ga.

Mr. H. R. Waterbury, whose appointment as manager of the Jacksonville, Fla., office of this company was announced in the September 16 issue, was born in Greenwich, Conn., thirty years ago, and learned telegraphy in 1901 while working as a reporter for the *Daily Advocate*, of Stamford, Conn. His first telegraph position was in Waterbury, Conn., and afterwards he became manager of the Postal Company's office at South Norwalk, Conn. Leaving this position, he joined the United States Signal Corps and after a seven-months' course in cable work at Washington, D. C., he was detailed to the United States cableship "Burnside," engaged in the laying of the Alaska cable. Upon the completion of this work he was stationed at the Juneau, Valdez and Seattle offices successively and was discharged in 1906 with the rank of sergeant. Mr. Waterbury then returned east and worked for the Postal Company in New York, afterwards, in 1910, going to Jacksonville for the same interests, where he filled the positions of branch manager and cashier.

H. R. WATERBURY,
Manager, Jacksonville, Fla.

An Old-Time Telegraph Construction Foreman.

One of the most prominent linemen in the Postal Telegraph-Cable Company's service is John R. Gorsuch, with headquarters at Philadelphia. He is an old-timer, having started his telegraph career in April, 1872, with the Franklin Telegraph Company, stringing two wires between New York and Philadelphia, and doing general repairs to the line between New York and Washington. Later he worked for the Atlantic and Pacific Telegraph Company, as well as for the Franklin Company.

JOHN R. GORSUCH,
Construction Foreman.

In the spring of 1878 Mr. Gorsuch went to the Continental Telegraph Company and when the latter company was absorbed by the Western Union Company, he became construction foreman for the Bankers and Merchants' Telegraph Company, which was then, in 1880, starting to build lines between New York and Philadelphia. During this work he had some odd and humorous experiences. Although on a peaceful mission he occasionally encountered some opposition on the part of farmers. He hired a team to drive through the country between the two cities in order to pick out a route for the new line, and naturally found it necessary to ask many questions of the natives in regard to the different roads, which made them suspicious of him. At noon one Sunday he arrived at a little town near Flemington, N. J., where he continued to seek information and was in turn questioned as to his business and what he was doing in that part of the country. His answers not proving satisfactory to the local

Digitized by Google

people, he was followed for several miles as he left the town, and at last had to give a more satisfactory explanation of his movements in order to prevent his going to jail as a horse thief.

Mr. Gorsuch was born on a farm near Bel Air, Md., September 30, 1848. He has been in the service of the United Lines and Postal Telegraph Cable Company since 1882 and was appointed to his present position of district foreman on April 1, 1891. He has made a splendid record for himself as a most capable foreman, and is as active today as he was twenty years ago.

Western Union Telegraph Company.

EXECUTIVE OFFICES.

Mr. T. J. Jones for many years connected with this company at Pittsburgh, Pa., has been appointed district commercial manager to fill a new position.

Mr. S. M. Cullison, special agent of the eastern division, New York, is again on duty after a two months' sickness caused by blood poison.

Mr. Willis H. Jones, electrical expert identified with the operating department of this company at New York for many years, and a valued and frequent contributor of telegraphic articles to TELEGRAPH AND TELEPHONE AGE for the past fifteen years, has been advanced to a position in the office of Mr. W. E. Athearn, engineer of equipment, with the title of engineering assistant.

Mr. Jones's success is an illustration of the personal advantage that comes from careful study and keeping in close touch with developments in telegraphy. He has established a nation-wide reputation as a writer of technical telegraph articles in a popular style, and by the use of plain, every-day language has been able to explain ordinarily difficult technical points so that the merest novice could grasp them. Mr. Jones's book of diagrams and information on practical telegraphy is a text book of the telegraph and is one of the most popular and successful works on telegraphy ever produced. His advancement is a fitting reward for his conscientious industry and close observation of things around him.

Mr. E. A. Baird, chief clerk to Mr. W. A. Sawyer, district commercial superintendent, New York, has been appointed manager of the Pittsburgh, Pa., office, vice Nelson E. Church, resigned. On October 5, the employes of Mr. Sawyer's office and many friends at 195 Broadway, New York, presented Mr. Baird with a Morris chair as a token of their esteem. Superintendent Sawyer in a few felicitous remarks made the presentation. Mr. Baird left New York on October 8, to take charge of his new position. He is succeeded at New York by Mr. T. J. Farrell of Mr. Sawyer's office. Mr. Farrell was for many years, prior to coming to New York, manager of this company's office at Bridgeport, Conn., where he made an excellent record as an official. He is one of the younger members of the fraternity, having been born in Newark, N. J., May 20, 1884. In September, 1898, he began his telegraphic career as a messenger in his native city afterwards becoming an operator. He has by diligent effort risen through various positions of importance, and he assumes his new position with an experience that well qualifies him for the exacting duties he will be called upon to perform.

Mr. Charles M. McCann has been appointed chief clerk to Mr. M. T. Cook, division commercial superintendent, Chicago. Mr. McCann was formerly assistant chief clerk to Mr. Cook.

Mr. George Bell has been appointed wire chief at Boston, Mass.

Mr. C. H. Daniels, special agent for this company with headquarters at San Francisco, Cal., has been appointed commercial agent for the second district of the Pacific Division, with headquarters at Seattle, Wash.

Mr. John M. Fair, manager of the Western Union Telegraph office, Grand Rapids, Mich., resigned that position recently, being succeeded by Mr. Frank S. Gould. Mr. Fair may engage in other business in the spring, after taking a rest on his farm at South Woodslee, Ont. He has been in the telegraph service for over thirty years and has worked in the principal cities from New York to San Francisco. He was located in Detroit, Mich., several years where he held important positions with the Western Union Company. In 1898 he was appointed manager at Saginaw, Mich., where he remained for six years, being then transferred to the managership at Grand Rapids. During his incumbency at Grand Rapids he popularized the Western Union service and the business was largely increased.

Mr. Thomas H. Gore, manager for the Western Union Telegraph Company, at Knoxville, Tenn., was born in that city, November 6, 1883. He entered the telegraph service in Knoxville for the Southern Railway Company, in January, 1901, and remained with that company for four years. He then entered the service of the Western Union Telegraph Company and worked in the Memphis, Tenn., and New Orleans, La., offices. Afterwards he became manager at Hamlet, and Raleigh, N. C., and then train dispatcher on the Seaboard Air Line. Subsequently he was manager for the Western Union at Athens, Ga., and afterwards manager of the Postal Telegraph-Cable Company's office at Lexington, Ky. He was chief operator of the Knoxville Western Union office at the time of his appointment as manager.

New Western Union Incorporations. — The Western Union Telegraph Company of Illinois has been incorporated with a capital stock of $25,000. The incorporators are Roy O. West, William Rothmann and Thomas G. Deering. The Western Union Telegraph Company of Indiana has also been incorporated, with a capital of $10,000.

TELEGRAPH AND TELEPHONE AGE is the leading paper in these two fields and is progressive and newsy. Subscription price, $2 00 per year.

The Telephone.

Purchase of Independent Telephone Companies.—Fifteen small independent telephone companies in New York State have been sold to the American Telephone and Telegraph Company.

Texas Telephone Lines Absorbed.—The Southwestern Telegraph and Telephone Company has purchased the lines of the Tri-State Telegraph and Telephone Company in the northeastern part of Texas.

Long Distance Telephone Service in Europe.—Telephone communication between Berlin, Germany, and Stockholm, Sweden, has been established by the use of the Egner-Holmstrom microphone.

High Telephone Station.—What is said to be the highest telephone station in the world is that on the summit of Mount Rosa in the Italian Alps. Its elevation is 14,960 feet above sea level. On account of its position, poles could not be used, therefore the wire was laid in the snow, which is very dry and a good non-conductor. The station is used for meteorological purposes.

Hamburg Exchange.—The new central telephone exchange in Hamburg, Germany, has a capacity of about 80,000 subscribers, and is one of the largest in the world. In the exchange 112,700 relays, controlling 70,000 incandescent lamps, are in use; 55,000 jack strips (1,100,000 single jacks) have been installed, 3,280,000 feet of flexible wire and a total length of 114,800,000 feet of leading wire were used, and 15,000,000 joints were made. The current for the microphones of the subscribers, for the signaling arrangements and the relays, is supplied from two accumulator batteries, each having a capacity of 7,800 ampere-hours, this being sufficient for 24 hours' working of the station. The total number of telephone operators (females) is 1,500.

Telephone Pioneers of America.

Active preparations are going forward for the first meeting of the Telephone Pioneers of America in Boston, Mass., November 2 and 3, and there is every indication that there will be a large attendance. Members in different parts of the country have signified their intention of being present. The headquarters of the convention will be at the Hotel Somerset.

Many of the members contemplate bringing their wives with them and a real enjoyable time is expected.

The first meeting will be called to order at 10 a. m., November 2, and the business of organization completed. In the afternoon addresses will be made by Dr. Alexander Graham Bell, Thomas D. Lockwood and other prominent telephonists.

Members desiring information regarding hotel accommodations are requested to address the committee of arrangements, which is composed of Messrs. Henry W. Pope, Charles R. Truex and Thomas B. Doolittle, 15 Dey Street, New York.

All those who wish to take advantage of the reduced rate from New York to Boston should notify the committee. A rate and a half round trip will be charged by train from New York, Pullman accommodations being $1.00 extra. The fare by boat will be $3.00 after November 1, plus $1.00 or $2.00 for state room.

The committee appointed on local arrangements at Boston consists of Messrs. W. J. Denver, chairman; G. H. Dresser, E. W. Longly, J. H. Barry, I. O. Wright and N. W. Lillie.

Mr. Francis A. Houston, general manager of the New England Telephone and Telegraph Company, says:

"On the evening of Thursday, November 2, the New England Company will entertain the visiting members and their wives at the theatre and on the morning of Friday, November 3, we will receive those who desire to visit our main exchange. On Friday afternoon an automobile excursion is to be arranged which shall include Concord, Lexington and suburbs of Boston. On Friday evening the American Telephone and Telegraph Company will entertain the Pioneers at a formal dinner at the Hotel Somerset. A separate banquet hall and entertainment for the ladies will be provided."

Mr. Henry McDonald of the American Telephone and Telegraph Company, Boston, is in charge of the arrangements affecting that company. The committee has authority to call upon any employe of the company to assist in the discharge of its duties. The organization committee is assured that every one will do his utmost to make the affair a great success.

It is proposed that the President of the Pioneers shall hold conversation with President Taft during the banquet, provided President Taft is within range of the telephone at that time, and arrangements are being made with this end in view.

Mr. Henry McDonald, chairman of Press and Hotel Committee, Boston, will reserve rooms, provided full particulars are given promptly.

Mr. R. H. Starrett, 15 Dey St., New York, chairman of Transportation Committee will provide special railroad rates if notified promptly.

The organization committee requests for exhibition any telephonic historical data that Pioneers may have, that is likely to be of interest and arrangements will be made to take care of such matters.

The 1912 Reunion of Old Timers.—The dates of next year's reunion of the Old Timer Telegraphers' and Historical Association and the Society of the United States Military Telegraph Corps, which is to be held in Jacksonville, Fla., are October 22, 23 and 24.

TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York, is headquarters for all electrical books published, foreign or domestic.

Digitized by Google

The Cable.

Tripoli Cable Interrupted.—The telegraph cable between Malta and Tripoli has been interrupted, cutting off telegraphic communication with Tripoli, the seat of war between Italy and Turkey. It is probable that the cable has been cut by one of the belligerents, as this is usually done in time of war.

Pacific Cable.—The report and accounts of the Pacific Cable Board, London, for the year ending March 31, shows a balance of £29,334 ($146,670) towards meeting the annuity of £77,544 ($387,720) in respect of interest and sinking fund on the capital of two millions sterling, an increase of £11,378 ($56,890) on the balance in 1909-10. The amount to be provided by the Imperial and Dominion Parliaments to make up the deficiency is, therefore, £48,210 ($241,050) for the past year. The Canadian land-line service was taken over by the Board in September last year, with satisfactory results, the average time of transmission between Great Britain and Australia being reduced by 15 to 18 minutes, and the accuracy of transmission being improved. A system of deferred messages at reduced rates is to be adopted within a few months. The number of international messages handled last year was 129,154, representing 1,849,613 words.

Radio-Telegraphy.

Wireless Between London and Continent.—A wireless station is being erected on the roof of the telegraph department of the British postoffice in London for the purpose of conducting experiments in wireless telegraphy with the Continent.

Uniting the British Possessions by Wireless.—It is reported from London that the experiments being conducted by Mr. William Marconi in New Foundland are part of a plan to unite various parts of the British empire by wireless with the Admiralty in London.

Wireless from Aeroplane.—At the recent flying meet at Brighton Beach, Coney Island, New York, wireless communication was maintained between George Beatty's aeroplane, while in the air, and the club house. John Dunn was the wireless operator who accompanied Mr. Beatty on his aerial trip.

Hertzian-Wave Fog Signals.—Three stations will be erected for the French government along the coast of France from which Hertzian-wave fog signals will be transmitted. Each station will emit a distinctive telephone note every thirty seconds, and repeat during ten seconds a letter of the Morse telegraph code. The telephone notes selected for the three stations correspond to given wave-lengths or frequencies.

Wireless Towers Not Necessary.—In his recent Newfoundland experiments in trans-Atlantic wireless transmission, Mr. William Marconi, it is stated, demonstrated that it is not necessary to have extensive towers erected in order that the work may be properly carried on. A wire run from the lighthouse at Fort Amherst to the top of the hill and attached to an ordinary pole has been found to do as good work as the most costly tower. In future therefore any station can be put up in a short time at a trifling expense and then taken down when the necessity for it has disappeared.

Wireless Telegraphy in the Kongo.—The Telefunken wireless station at Boma, now in operation, has an aerial of 53 meters (173 feet) in height. It is a one and one-half kilowatt station and generates its electricity by an eight horse power petroleum motor. The station at Banana is of the French Ferrier type, with an aerial 37 meters (121 feet) in height. It is at present a one and one-half kilowatt station, but will shortly be increased to five kilowatts. The same power to generate electricity is used as at Boma. The Telefunken engineers are now erecting a five-kilowatt station at St. Paul de Loanda.

Wireless Regulations in Australia.—The Postmaster General of Australia has issued regulations in which provision is made for the issue of general licenses at 5 shillings ($1.22) each for ships registered in Australia and for experimental licenses at £1 1s. ($5.11) each. The appliances on board ship are to be worked in such a way as not to interrupt or interfere with the naval or military signaling or the transmission of messages between other wireless telegraph stations. Except by permission of the Postmaster General the wireless aboard any ship (other than a ship of war) are not to be worked while the ship is in any harbor or any territory of the Commonwealth. Power is given to the Governor General to prohibit the use of wireless telegraphy on board foreign ships in territorial waters in case of emergency.

Obituary.

Frank S. Adams, aged 55 years, formerly manager of the Western Union Telegraph office at Henderson, Ky., died at Nashville, Tenn., September 23.

Peter J. Morrison, aged 65 years, one of New York's prominent telegraphers thirty years ago, died at his home in Brooklyn on October 2. Mr. Morrison was an operator in the main office of the Western Union Telegraph Company at 195 Broadway, New York, in the early eighties. He studied law while working at the key and was admitted to the bar, but never practised his new profession, except to attend to some legal matters for the Western Union Company. He was the head of the Brooklyn local counsel of the telegraphers' union at the time of the strike in 1883. After that memorable movement he never returned to the telegraph service. He identified himself with the brokerage business in New York in which he remained until the time of his death. The old guard was represented at the funeral by Messrs. John Costelloe, John J. Cochrane, Daniel C. Donohue, Frank Maier and T. J. Cusack.

Annual Report of the Western Union Telegraph Company.

The annual meeting of the stockholders of the Western Union Telegraph Company was held in New York, October 11. The report of President Theo. N. Vail for the year ending June 30 shows the following results as to the financial operations:

INCOME ACCOUNT.

Gross Telegraph Earnings		$34,714,810.07
Miscellaneous Earnings		763,982.81
Total Earnings		$35,478,792.88
Deduct:		
Operating Expenses, including rent of Leased Lines, Reconstruction Repairs, Miscellaneous Interest, etc.	$29,153,631.63	
Taxes	900,000.00	
		30,053,631.63
Balance		$5,425,161.25
Add—Income from Loans and Investments, including Rentals from Real Estate		1,680,196.23
Net Profits		$7,105,357.48
Deduct:		
Interest on Bonds of the Western Union Telegraph Company	$1,733,389.52	
Dividends:		
Paid Oct. 15, 1910	$747,770.25	
Jan. 16, 1911	747,801.75	
Apr. 15, 1911	747,846.00	
July 15, 1911	747,886.50	2,991,304.50
		4,724,694.02
Balance transferred to Surplus Acct.		$2,380,663.46

TELEGRAPH LINES AND EQUIPMENT.

The increase in this amount for the year of $3,524,608.25 is made up of approximately $2,300,000 expended during the year for the completion of the Bay Roberts cable and approximately $1,200,000 spent in the construction of land lines.

The total cost of the Bay Roberts cable was $3,334,402.92, of which sum $1,037,093.39 was expended prior to June 30, 1910. Under the provisions of the proposed lease with the Anglo Company, it is provided that the cost of this cable shall be repaid to the Western Union Company.

There have been added to the company's plant during the year 1,403 miles of poles and 58,296 miles of wire, the latter consisting of 43,082 miles of copper wire and 15,214 miles of iron wire. On June 30, 1911, there were 24,926 Western Union offices.

GENERAL.

Notwithstanding the existing unsettled conditions of business, such as have heretofore caused a decrease in gross revenue, there has been an increase of $3,018,964—9.57% in total revenue. The increase in the message tolls was $3,153,122—12.58%. The only decrease was on the leased wires, which was nearly $400,000, or 15.31%. This was probably due to the rigid enforcement of the rules and regulations respecting the uses made of these wires by the lessees.

The large increase in gross is more than offset by the increase in the expenses of $3,167,853—13.14%, causing a decrease of $148,889 in the net revenue. Of this increase in expenses $2,369,434 was for salaries and wages, an increase in this item of 21.18% over last year.

While your company has had a great past, and cannot fail to have as great a future, present conditions, resulting from a long period of unsettled business and labor conditions and of economies and retrenchment, are, from a conservative standpoint, far from satisfactory.

Without going into detail, there still exists a necessity for the doing of many things which cannot be ignored. Salaries and wages to be readjusted, an effective and beneficial pension scheme to be inaugurated that good men may not only be retained, but encouraged and made to feel that the interest and prosperity of the company works for their interest and prosperity. Offices and apparatus and general surroundings to be improved, brightened up, that all work may be done under decent and sanitary conditions. Plant to be reconstructed, that promptness and efficiency may be required and obtained.

Considerable has been done in these directions, but much remains to be done, and when done there is no doubt but that the result will be increased economy and efficiency in the work and service, to the direct advantage of both your company and the public.

DIVIDENDS.

In order that public confidence may be strengthened not only in the ability of your company to continue any dividend disbursement which may be established in the future, but also confidence in its possibility to restore your company to a reasonable dividend-paying basis, it is proposed to carry to depreciation reserve all earnings over and above the present dividend, to charge such construction to that reserve as the directors may deem expedient, and to continue this procedure until such a time as the fund would in the opinion of your directors admit of an increase in your dividend rate.

NEW SERVICES.

The telegraph business of the past has been built upon, and all the traditions surrounding it are almost exclusively on, the idea of expedition or immediate service with a large surplus of facilities and operating staff, equal at any time to the maximum demand, and consequently idle much of the time. These surplus facilities, together with the cost of the insurance against damages for delays, avoidable or unavoidable, required for expedited business, necessitate higher charges for this class of service than if the business were handled so as to keep both plant and staff occupied to a fair maximum capacity. Unexpedited business would result in some delays to a part of the business, but the operating cost and plant charges would be so much reduced that a very appreciable reduction in the rates could be made.

There is, however, a great quantity of important business that demands expedition and is perfectly able and willing to pay for such expedition. To this class of business a retarded service with lower rates

Digitized by Google

presents no attraction. Any increase in the use of or introduction of new uses for the idle and unused plant will reduce the cost per unit of service, or enable some other service to be given at a cost within the value of such service to the public. It was the belief that there was a large business which lay in value and importance, so far as transmission was concerned, between the expedited telegram and the ordinary mail that caused the introduction of the Day Letter and the Night Letter. When these new services become assimilated by the working organization, and the changes and innovations in plant and operating force now going on are in full working order, it is believed that some new and popular services, additional to those now in effect, can be given.

The "Night Letter" was intended to be an improvement and advance upon the "Night Telegram." In starting it the company took little risk beyond possible small increase of operating expenses. With the "Day Letter" the case was different. The revenue from excess words in regular telegrams over and above the amount charged for the "Day Letter" is several millions of dollars. All these millions of revenue would be lost if the "Day Letter" was used in place of long messages at regular tolls, whenever the charge for such messages exceeded the charge for Day Letters. Experience has shown the revenue from the Day Letter to be a substantial one, while the revenue from other forms of telegraphic service is not materially affected thereby. That the Day Letter has created its own place in the business of the company, and that there was and is a place for the Day Letter in the transaction of the country's business is shown by the results.

TELEPHONE AND TELEGRAPH RELATIONS.

Progress has been made in the direction of joint occupancy and joint use of facilities, largely, however, in the working out of arrangements and details of working. Progress in this direction is apparently slow because of the many details to be arranged and solved, all of which—though not insurmountable—are complex and much involved. The apparent progress of the future will be greater. All reconstruction, as well as construction, is being done on lines which will make your plant available for long distance telephone business and short distance telegraph business by telephone in connection with the Bell system.

PENSIONS.

The Committee on Pensions has been engaged in the collection of data necessary to enable the actuaries to give figures on benefits and expenses. This work has been somewhat delayed by the absence in Europe of vice-president Clark, the chairman of the Committee. The work will be necessarily slow, as it is desired that any pension scheme which may be established will, in case of disability, give material aid and benefit to those who have been for a few years only in the service of the company, as well as to those of long service. Whatever scheme is put in operation will take into consideration past service, and will therefore involve a large expense from the very start. While the general scheme is being worked out, all necessitous cases are being provided for.

TRANSATLANTIC CABLES.

There is very little additional to what has already been laid before you. The proposed arrangement, if ratified, will put the Western Union in a position where it can handle the transatlantic cable business in a manner which will be in accordance with its importance and to the satisfaction of the public, something that has been impossible neretofore.

The charges assumed are about the equivalent of the dividends which the two companies have been making from the business, and everything indicates that under any probable future conditions the transatlantic cable business will be a source of profit instead of a loss to the Western Union, as heretofore.

Under the arrangement the Western Union is reimbursed for the cost of the new cable laid last year, amounting to $3,334,402.92, and is relieved from the large additional investment, amounting to twelve to fifteen millions, involving the duplication of existing facilities now only partially utilized, which would have been necessary had these arrangements not been made.

The Anglo-American and the Direct United States Cable Companies have at their preliminary meeting unanimously ratified the proposed arrangement, and this action will without doubt be confirmed in all statutory proceedings to follow.

The lease of the Direct and Anglo-American cables was ratified unanimously, and the old board of directors was re-elected.

At meetings of the stockholders of the Anglo-American Cable Company and the Direct United States Cable Company in London, September 29, the agreements to lease their lines to the Western Union Telegraph Company for a period of ninety-nine years was unanimously approved.

Telephone and Telegraph Society of New England.

The Boston Plant Chapter of the Telephone and Telegraph Society of New England held its second regular meeting in Boston October 10. The new method of accounting, so far as it affects the workman, was thoroughly explained and discussed by Mr. F. X. Colleton, special agent for the superintendent of plant, and Mr. H. C. McKay, plant accountant, Boston and southern Massachusetts divisions.

A course of short talks on the fundamental principles of electricity in their direct application to telephone apparatus was started at this meeting, also a Question Box. Telegraph employes are welcome at these meetings.

Mr. Gordon S. Wallace, 125 Milk Street, Boston, Mass., is secretary of the Chapter.

Mr. L. E. Rudd, manager of the Western Union Telegraph Company at Memphis, Tenn., in renewing his subscription says: "You did exactly right in renewing my subscription to TELEGRAPH AND TELEPHONE AGE. I do not feel that I can keep house without your paper."

Sending the First Cable Messages to Europe.*

BY J. B. VAN EVERY, VICE-PRESIDENT, WESTERN UNION TELEGRAPH COMPANY, NEW YORK.

On July 29, 1866, the first successful Atlantic cable was opened for public traffic and the office of the Western Union Telegraph Company at No. 145 Broadway, New York, became the centre of popular interest. The scene, with its curious costumes and conditions, is preserved in the sketch made by an artist of *Harper's Weekly*, a copy of which is now preserved at Western Union headquarters and reproduced herewith.

SENDING CABLE MESSAGES FROM 145 BROADWAY.

Almost simultaneously with the opening of the cable the Western Union Telegraph Company had taken possession of the office building at No. 145 Broadway, through the absorption of the last of its great rivals of that day. Previous to that time, its headquarters had been at Rochester, N. Y., and its lines were principally in the Middle West. But in 1866 negotiations were completed for the Western Union to buy its rival, the American Telegraph Company, which controlled the principal lines along the eastern seaboard.

On the night of July 31, 1866, the officers of the Western Union left Rochester for New York City to take possession of the American company's offices and property. I remember that we young clerks in the party thought it a historic trip, and so it was in telegraphic history.

Our president, Mr. J. H. Wade, was not on the train. I think he already was in New York, where he had been conducting the negotiations for the consolidation. Vice-president R. R. McAlpin headed our party, and accompanying him was Mr. O. H. Palmer, the secretary and treasurer. There were a number of minor officials and clerks; I was among the latter, and I remember spending the evening on the cars with Mr. R. Hart Rochester, who was then a clerk like myself, but afterwards became treasurer of the company and filled that position for many years.

We arrived in New York on the morning of August 1, and going down to No. 145 Broadway, which had been the headquarters of the American Company, we took possession of the offices. I re-

*From *Journal of the Telegraph.*

Digitized by Google

member that Dr. Norvin Green, who afterwards became president of the Western Union, was there when we arrived. He had just made an announcement to all the American employes that they were discharged because new proprietors were coming into possession, and there was much gloom around the place. But most of the men were immediately re-employed by the Western Union management. Dr. Green was then connected with the American Company, which had absorbed his Southwestern lines earlier in 1866.

The laying of the Atlantic cable had been completed on July 27, with the arrival of the *Great Eastern* at Heart's Content, Newfoundland, and various private messages were being sent over the wires. A few days after the Western Union had become the all-powerful land telegraph company, and moved to New York, the cable began commercial business.

The rates were high. The minimum charge was $100 for a message of twenty words or less, five letters counted as a word, or as the public figured it out a dollar a letter. The cable was owned by the Anglo-American Cable Company, whose headquarters were in London. It maintained no offices in the United States, the Western Union receiving and delivering all the messages therein as well as in a portion of Canada.

Meeting of International Electrotechnical Commission at Turin.

At the meeting of the International Electrotechnical Commission which was held at Turin, Italy, September 7-16, the following letters were definitely adopted for the international representation of the quantities entering into the algebraical expression of Ohm's law:

Current I
Electromotive force .....E
Resistance .....R

Mr. Gano Dunn, president of the American Institute of Electrical Engineers, and a former telegrapher, invited the commission to hold an official meeting at San Francisco in 1915, on the occasion of the Panama Pacific Exposition, to be held in celebration of the opening of the Panama Canal.

The following resolution was adopted: "The International Electrotechnical Commission expresses its willingness to hold an official meeting at San Francisco in 1915, and instructs the central office, on the request of the American Institute of Electrical Engineers, to co-operate with it in the organization of an International Electrical Congress at San Francisco at the same time."

Nineteen countries were represented, the delegates from the United States being Messrs. Gano Dunn and C. O. Mailloux; Professor Elihu Thomson and Drs. A. E. Kennelly and C. H. Sharp. Both Mr. Dunn and Dr. Kennelly are former telegraphers.

Any book on electrical subjects can be obtained at the office of Telegraph and Telephone Age, 253 Broadway, New York.

QUESTIONS TO BE ANSWERED.

[One of the most effective means of imparting information is to ask and answer questions, the value and power of this method being due to the fact that the information given in an answer is specific and direct. Asking questions for the student to answer for himself has proved to be an excellent means of education, as it promotes and encourages concentration of thought and investigation in order to arrive at the correct answer. There is a general demand for knowledge on the quadruplex, duplex, etc., and to aid in the acquirement of such knowledge we are extending our aid to students by asking questions on these subjects in each issue of our journal, so that they may be encouraged in their studies by answering them. We use as our text book Maver and Davis' "The Quadruplex," and students should have a copy of this book at hand in order to be able to give the answers. The questions are progressive and a careful reading of the book on the points under inquiry unfold the answers. This method of acquiring technical knowledge is a fascinating one.]

CHAPTER IX (*Continued*).

In balancing a quadruplex, what is the first request to make of the distant (B) station?

Having grounded the line at B, what is the next step in the work?

What is the ground coil, and what is its purpose?

Should the resistance in the ground coil be altered?

If altered, what would be the effect upon the balance?

With the line grounded at *A* and *B*, what is the next step in balancing?

After cutting in the home battery what is done next?

In balancing what is the effect of line induction upon the No. 1 relay?

When inductive effects are manifested what should be done?

If the wire is much out of balance what will be the effect upon the polar relay armature?

After having obtained a balance with the home battery to line, what is to be done next?

When *B* cuts in his battery what is the usual effect upon the inductive disturbance?

Under what conditions may condensers be dispensed with in balancing a line?

Study the analogy between a water pipe and a wire statically charged.

What is the effect of induction upon a wire, considered as a reservoir of electricity?

Is there a time when the polechanger cuts off the supply of electricity to the line?

The line being charged with electricity, what becomes of the charge when the source of current is cut off temporarily by the polechanger?

What is the effect of the charge (static) upon the relay when it returns to ground, or earth?

How does the condenser counteract the effect of the line discharge upon the relay?

Do the coils in the rheostat have as great a capacity for retaining an electric charge as does the line itself?

Why is the condenser placed in the artificial line?

How is it charged and how is it discharged?

When it discharges, how does the charge pass through the home relay coils, and why?

The New Western Union Telephone Building in New York.

Some additional facts are at hand regarding the construction and equipment of the new building being erected in New York for the joint use of the Western Union Telegraph Company, the American Telephone and Telegraph Company, and the New York Telephone Company.

The plans contemplate accommodations for 2,600 telegraph employes at one time, should the demands for operating forces require that number.

It is probable that the traffic and plant departments of the Western Union will move from the present quarters at No. 195 Broadway to the new building about January 1, 1913, but the executive offices will remain in the old building.

The assignment of telegraph space is to be as follows: A receiving department is to be located at the easterly end of the main entrance in Walker Street and will be arranged so that the general entrance to the building will also serve the patrons of the telegraph company who desire to file telegrams there. This booth will be connected with the operating department by pneumatic tubes.

About one-half of the space on the eleventh floor is to be assigned to the female employes for rest rooms, lavatories and locker rooms, and the remaining space will be temporarily occupied by the district offices until such time as it is required for enlarging the employes' quarters.

Two-thirds of the twelfth floor will be given up to the male employes for rest rooms and the remainder of the space to district offices until such time as the growth of the operating force demands the entire twelfth floor for quarters.

The thirteenth floor will be used by the plant department for the accommodation of main cross-connecting racks, switchboards, repeater tables, multiplex apparatus and a motor-generator plant. This equipment will consist of approximately forty-five sections of main line, city line and multiplex loop boards at the time of initial occupancy and of about seventy-five sections by the year 1930. The cross-connecting frames will accommodate approximately 20,000 and 36,000 wires for the initial and 1930 periods respectively.

The transmission and reception of telegrams will be entirely excluded from this floor and all communication between the switchboards, multiplex sets, repeaters, etc., and the operating rooms will be effected by means of a very elaborate signaling arrangement, which will permit instant communication between any and every operator's position and the switchboard and repeater attendants.

All Western Union underground cables will occupy a large cable vault in the basement, jointly with the cables of the telephone company. They will be brought up in three-inch vertical tile ducts rising from the cable vault to the thirteenth floor. There are to be eighty-five of these ducts exclusively for Western Union cables.

There is to be a complete arrangement of switchboards and telegraphic equipment to permit a liberal interchange of facilities with the plant of the American Telephone and Telegraph Company, which is to occupy other floors in the same building.

The operating department will occupy the fourteenth and fifteenth floors and ultimately the sixteenth and seventeenth floors, it being the plan to move the other departments to other floors or to space in adjacent buildings as demands may require.

The sixteenth and seventeenth floors will be constructed so as to permit conversion into operating rooms without recourse to structural changes, when desired.

It has been already decided that there must be no human element of delay between the time a telegram is received from a wire and the time it reaches the routing department. To accomplish this means automatic conveyance of telegrams from every operator's position direct to the routing table.

Special tables, known as concentration tables, are being devised that will permit grouping a multiple of circuits on one table or a group of tables equipped with signal and switching devices to insure the maximum output with the minimum delay.

The operating department is to have an extensive pneumatic tube system connecting with many of the important branch offices. The power plant for the pneumatic tubes is to be located in the basement. Efforts are being directed to make all equipment in the plant and operating departments of non-inflammable materials as far as practicable.

The sixteenth floor will be occupied by the bookkeeping department until such time as it is needed as an operating room. There will be desks provided for 250 clerks, together with the filing cases for this department.

On the seventeenth floor is to be located an employes' dining room, which is to accommodate 325 people initially and 475 ultimately. In addition to the dining room, there will be located on the seventeenth floor a telephone room for the reception and delivery of telegrams by telephone. This room is to have an ultimate capacity of one hundred telephone operators, it being the plan to develop this branch of the service to its maximum capabilities.

Further details regarding the new building were given in our issues for February 16 and September 16.

Evening Course in Telegraphy and Telephony at Columbia University.

Recognizing the need of a course of technical instruction in the allied arts of telegraphy and telephony to be conducted in the evening and open to men employed during the day time, a regular course will be inaugurated at Columbia University, New York, commencing early in October.

A Modern Messenger Boy.—A telegraph messenger in Tarrytown, N. Y., Max Schwartz by name, has discarded the use of a bicycle in the delivery of messages because he states it is too slow. It takes too long to push the bicycle up the hills, so he prefers to run.

Improved Pole Changer.

BY STEPHEN D. FIELD, OF STOCKBRIDGE, MASS.

The arrangement of apparatus shown in the accompanying illustration is the outgrowth and may be considered as an improvement on the continuity-preserving pole changer illustrated in TELEGRAPH AND TELEPHONE AGE August 1. The advantages which it possesses over existing methods is that all passing signals are at all times audibly recorded exactly as they go to line thus ensuring accurate and constant supervision.

The signals are primarily transmitted by the relay contacts subsequently reinforced and emphasized by those on the sounder lever. The contacts are absolutely continuity-preserving and sparkless thus ensuring an easy and continuaus balance. The re-

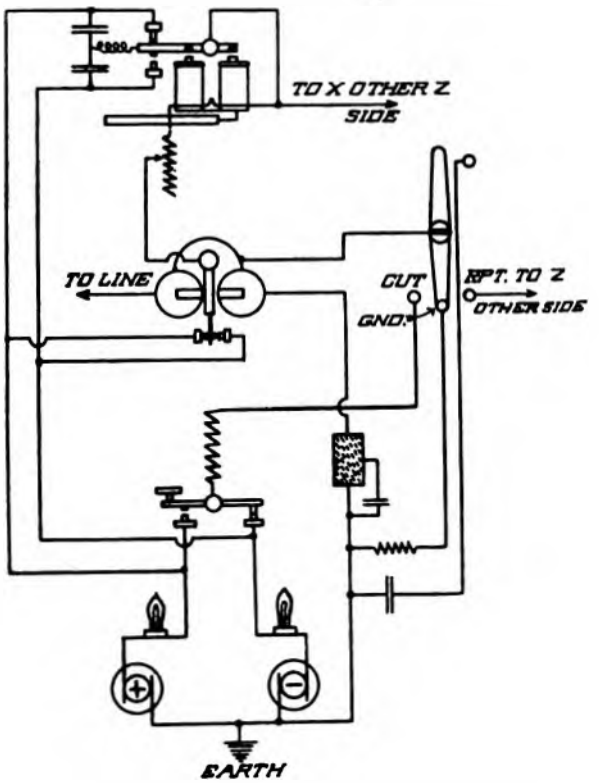

DIAGRAM OF IMPROVED POLECHANGER.

versal is graduated so as to put current to line with a speed which the line can accommodate, the currents being transmitted in wave form rather than in the abrupt manner incident to circuit-breaking pole changers.

The sounders are entirely insensible to incoming line currents, such currents balancing on the twin condensers attached to the sounder lever. If they add to the charge in one an equal amount is subtracted from the other. An impedance about equal to that of a four ohm sounder is placed between the sounder lever and twin condenser. This prevents welding of contacts in case of accidental manual manipulation of the sounder lever when the battery is connected. Under ordinary operation no sparking or welding is noticeable.

The polar sounder employed has four coils connected to a permanent magnet, after the Hughes type. These coils are connected in series opposition, and have a combined resistance of about one hundred ohms.

In operation, when the relay moves from one contact to the other it diminishes the line battery in any desired amount determined by the choking action of the sounder magnet and its allied resistance. At this instant one of the condensers is discharged through the sounder magnets thus actuating the sounder lever which, on leaving its contact (not on completion of stroke) instantly accomplishes a modulated reversal.

Upon completion of the excursion of the sounder lever all extra connections are removed from the circuit and full unhampered current passes to the line in the reverse direction to that existng at first.

So perfectly can these signals be modulated that fair telephonic transmission can be had on the same line without any further compositing device other than the relays usually in circuit.

The inductive effect on parallel circuits is at once reduced to a minimum.

An impedance in the key circuit acts in conjunction with the condenser as shown, thus serving to modulate the signals when the apparatus is "cut" for testing or balancing.

When the apparatus is cut for local distribution, an extra contact is provided on the polar sounder lever, and a pole changer substituted for the key.

Though illustrated as a polar duplex it is obvious that the apparatus is adapted to use as a pole changer on quadruplex circuits with equal advantage.

Telephone Texts in Scriptures.

The *Bell Telephone News* publishes a list of texts contained in the Bible which could be construed as pointing to the invention and operation of the telephone. We reproduce a few of them herewith:

Their line is gone out to all of the earth and their words to the end of the world. Ps., xix., 4.

We have no might against this great company. II Chron., xx., 12.

Now, shall this company lick up all that are around about us? Num., xxii., 4.

The great city was divided into three parts. Rev., xvi., 19.

Charge the people! Exodus, xix., 21.

Is there any number? Job, xxiv., 3.

The number is 666. Rev., xiii., 18.

When I call answer me speedily. Ps., cii., 2.

Where is the receiver? . Isa., xxxiv., 18.

They could not take hold of his words. Luke, xx., 26.

I said in my haste "I am cut off." Ps. xxxi., 22.

If he cut off, and shut up, who can hinder him? Job., xi., 10.

I will cut him off. Lev., xxvii., 10.

Rebuke the company. Ps., xviii., 30.

What word is this! Luke, iv., 36.

Thou hast nothing to pay. Prov., xxii., 27.

Wherefore kick ye? I Sam. ii., 29.

Twenty and three! Judges, x., 2.

CHANGES OF ADDRESS.—In ordering a change of address the old as well as the new address must be given.
REMITTANCES to Telegraph and Telephone Age should be made invariably by draft on New York, postal or express money-order, and never by cash loosely enclosed in an envelope. By the latter method money is liable to be lost, and if so remitted is at the risk of the sender.

October 16, 1911.

A Glimpse of a High Power Wireless Station.

Very few persons outside of the elect have any idea how a transatlantic wireless telegraph station is worked. These stations are necessarily of high power and their equipment usually embraces apparatus and refinements that it is desirable shall not be seen by vulgar eyes

A ray of light has been given to the world revealing the inner operatiohs at the great wireless station at South Wellfleet, Mass., from which news service in transmitted each night to ships at sea. The story is exceedingly interesting and we reproduce it on other pages in this issue. It reveals many facts that are not generally known regarding this class of service, and shows in a general way what has been done to insure success of operation and the attainment of results.

It is interesting to note that the news dispatches sent each night to the ships at sea are transmitted automatically from perforated tape, and that the same dispatches are sent out into space several times in order to make it certain that the receiving operators on the ships shall not miss any portion of them.

The operation of a high power, long distance wireless plant is vastly different from working a Morse land wire. It may be likened to a circuit with transmitting apparatus at one end and receiving instruments at the other, and nothing more—no key at the receiving end with which to "break." If the wireless receiving operator on any of the ships fails to get all that is coming to him at one transmission what he does not get would be irretrievably lost were it not for the retransmissions. That is why the news dispatches sent out from Cape Cod are transmitted several times. By this means the receiving operators are reasonably sure of getting every signal, although some letters or words may have gone astray during one or more of the transmissions. By putting the parts together, however, the complete despatch is the result.

Apart from the interesting description of the routine at this station the impressive fact is forced upon us that the managers of this system are doing everything that good judgment and science can suggest to secure useful and practical results.

On account of the great noise of the sparks this station has been dubbed "Marconi's thunder factory." It may not be possible to steal his thunder very well, but it is possible to steal his lightning while it is on the wing.

The Telephone as a Life Saver.

The recent disaster at Austin, Pa., resulting from the bursting of a dam, furnished the occasion for another demonstration of the great value of the telephone in emergencies. In this instance it was the means of saving probably hundreds of lives. In itself of course it could do nothing, but backed by cool human brains it warned scores of people of the impending danger, many of whom no doubt would have lost their lives had they not been thus forewarned. The telephone operators who stuck to their posts in the face of the danger and spread the danger alarm to as many people as they could reach by wire, will go on record as heroines as they deserve. Their brave acts were most praiseworthy and are entitled to the highest public recognition. The telephone company, we understand, has rewarded them in a substantial manner for their bravery. The mere expression of admiration for a brave act is a cheap way of showing appreciation. but a substantial increase of salary at such a time is more expressive than all the compliments that can be uttered.

Order to Re-establish Branch Office in Baltimore.

The Maryland Public Service Commission has ordered the Western Union Telegraph Company to re-establish its branch office in the Belvidere Hotel at Baltimore

The case has been in dispute for several months. The Western Union and Postal Companies closed their offices in the hotel because they were requested to move the offices from the lobby to the basement. The hotel company appealed to the Public Service Commission to compel the telegraph companies to return, but lost its case. In the case just closed against the Western Union the Commission decided that it has the power to require the establishment of offices in a given locality and in a certain building.

The company contended that the nearby office on Richmond Street was sufficient for the needs of the hotel patrons but the Commission thought otherwise after summing up a report of the business done in the two offices.

Mr. D. Harrison, manager of the Western Union Telegraph Company. Atchison, Kan. writes: "Here's $2.00. Keep sending your paper until I 'break' or get broke."

Joint Telephone and Telegraph Sign.

The American Telephone and Telegraph Company and the Western Union Telegraph Company have adopted a joint sign for their offices and it is now being manufactured for general use.

The design of the sign is shown in the accompanying illustration. The familiar telephone sign is coupled with that of the new Western Union em-

JOINT TELEPHONE AND TELEGRAPH SIGN.

blem, by the words "Universal Service," which are very appropriate and significant.

The sign is of the enamel type, the lettering and design being in blue, against a white background.

Magnetic Club Dinner.

The autumn dinner of the Magnetic Club will be held at the Hotel St. Denis, New York, Wednesday evening, November 15. The officers and members of the executive committees of the Old Time Telegraphers' and Historical Association, and the Society of the United States Military Telegraph Corps, have been invited to attend the dinner as the guests of the club.

The out-of-town delegates to the annual meeting of the Telegraphers' Mutual Benefit Association, which is to be held on the afternoon of the same day, have also been invited to attend the Magnetic Club dinner.

The greater part of the evening will be devoted, as usual, to an entertainment, although some of the guests will be invited to make brief addresses.

Telegraph and Telephone Stock Quotations.

Following are the closing quotations of telegraph and telephone stocks on the New York Stock Exchange October 9:

Western Union Tel. Co.	79⅛
Mackay Companies	85
" " pfd.	73½
Amer. Telep. and Teleg. Co.	134

DIVIDENDS.

A dividend of two dollars per share will be paid on October 16 to stockholders of the American Telephone and Telegraph Company.

The Western Union Telegraph Company will pay its stockholders 75 cents per share on the same day.

The Mackay Companies paid its shareholders $1.25 per share on common stock and $1.00 on its preferred stock on October 1.

Members of the telegraph fraternity are large holders in the stocks of the telegraph and telephone companies, over $2,000,000 in the Mackay Companies being held by them, and fully $4,000,000 of American Telephone and Telegraph and Western Union stock is registered in the names of persons identified with these interests.

Our Subscription Contest.

Interest in our subscription contest is rapidly growing and our agents are exerting themselves to get new subscribers to TELEGRAPH AND TELEPHONE AGE and incidentally win one of the prizes offered for their work.

The conditions of the contest were given on page 594 of our issue for September 1. There are five prizes, as follows: First, $50; second, $25; third, $15, and fourth and fifth, $5 each. The contest is limited to new subscriptions and renewals only. The total amount received from each agent on this account will decide the contest. In the event of a tie on any one prize, the prize will be divided.

In offices where there is no regular agent for this journal an agency may be established by securing an appointment, and any reliable person can thus enter the contest. An agent in a small office has just as good a chance to win as has the one in a large office, and it is desired that many more new agencies be established. There are many telegraphers throughout the country who are not subscribers, but who ought to be for their own good.

The contest will close December 20, therefore there is ample time for hustlers to enter the lists and make a record.

TELEGRAPH AND TELEPHONE AGE is a better paper now than it ever has been, and we expect to improve it with each issue. It is not stagnant; it is progressive, and, all telegraphers should be progressive by reading it carefully. It has good claims for greatly enlarging its subscription list and agents should point out the excellent features of the paper to prospective subscribers.

London Electrical Exhibition.—An electrical exhibition was opened in London on September 23 and the postoffice exhibit (telegraph and telephone) was an extensive one. The telephone exhibit consisted of a working exchange, the equipment being of the latest common battery type. Two demonstration telephones were provided in order to show visitors the various steps taken in dealing with a telephone call. The telegraph exhibit comprised sets of modern apparatus in working order. Chief among these was the Wheatstone A B C apparatus, which is used chiefly at small country postoffices where the assistants are unable to use the ordinary Morse instruments. The Hughes type-printing apparatus was also shown. There was also an extensive exhibit of early telegraph and cable apparatus, etc.

American Engineers and Engineering. — Mr. Carl S. Dow is the author of an article in the *Chautauquan*, entitled "American Engineering." A large part of the article is devoted to a description of the work of Mr. Thomas A. Edison and of Prof. Alexander Graham Bell, and portraits of these two gentlemen are shown.

Course of Instruction in the Elements of Technical Telegraphy.

(*Copyrighted.*)

INTRODUCTION.

We begin in this issue the publication of a course of instruction in technical telegraphy, which was prepared as a correspondence school course by Mr. J. H. Penman, of Rockport, Mass., an electrical engineer of ability and high standing. Credit is also due to other engineers and experts who furnished, through the columns of TELEGRAPH AND TELEPHONE AGE, much of the material upon which the lessons are based.

The course is published for the benefit of those of our readers who desire to fit themselves for better positions in their vocation. It is elementary throughout and will be divided into chapters, following one another in logical order. It necessarily starts with a brief review of elementary mathematics in order to freshen the memory on this important branch of knowledge, for telegraph engineering, in common with all other branches of engineering, is based on mathematics.

The course has received the hearty commendation of telegraph officials and experts for its scope and accuracy and its sound practicability. In each chapter examples will be given in order to illustrate the application of the rules to practical cases, and each chapter will be followed by a series of questions pertaining to the subject of the chapter, to be worked out by the student in order to review his progress.

In the first lesson in arithmetic we have omitted everything up to fractions, and begin the work from that point.

LESSON I.

FRACTIONS.

The term above the horizontal line of a fraction is called the *Numerator;* the lower term, the *Denominator.* The *value* of a fraction is the numerator divided by the denominator, as $\frac{4}{2} = 2$, $\frac{6}{2} = 3$.

The line between the numerator and denominator, or the sign $\div$ means *divided by.* Thus, $\frac{5}{6}$ is equivalent to $5 \div 6$.

The value of a fraction whose numerator and denominator are equal is 1. Thus, $\frac{4}{4} = 1$.

A *proper* fraction is one in which the numerator is less than the denominator, as

An *improper* fraction is one in which the numerator is not less than the denominator, as $\frac{6}{5}$, $\frac{10}{7}$.

A mixed number is a whole number and a fraction united. $4\frac{2}{3}$ is a mixed number, and is equivalent to $4 + \frac{2}{3}$.

Fractions whose denominators may be any number, whole or fractional, that is, common or ordinary fractions, are called *vulgar,* whereas fractions whose denominators are 10, 100, 1,000, and so on, are called *decimal* fractions.

A fraction is reduced to lower terms by dividing both terms by the same number. Thus $\frac{4}{12}$ is reduced to $\frac{1}{3}$ by dividing both terms by 4.

To reduce a mixed number to an improper fraction:

RULE (1). *Multiply the whole number by the denominator of the fraction, add the numerator to the product, and place the denominator under the result.*

Example: Reduce $37\frac{3}{4}$ to an improper fraction.

Solution: $37 \times 4 = 148$; $148 + 3 = 151$;

$37\frac{3}{4} = \frac{151}{4}$. Ans.

To reduce an improper fraction to a whole or mixed number:

RULE (2). *Divide the numerator by the denominator, the quotient will be a whole number if the division is even; if there be a remainder it will be the numerator of the fractional part of which the denominator is the same as the denominator of the improper fraction.*

Example: Reduce to a mixed number $\frac{701}{6}$.

Solution: $701 \div 6 = 116$ and 5 remaining. The denominator of the improper fraction being 6, the remainder becomes $\frac{5}{6}$, and the mixed number is thus $116\frac{5}{6}$. Ans.

A *common denominator* of two or more fractions is a number which will contain all of the denominators of the fractions without a remainder.

The *least common denominator* is the least number that will contain all the denominators of the fractions without a remainder.

To find the least common denominator:

RULE (3). *Divide each of the denominators by some whole number which will divide, if possible, two or more of them without a remainder, bringing down these denominators, which will not contain the divisor without a remainder, to the row below; continue doing this until the last row contains only 1's, when the product of all the divisors is the least common denominator.*

Example 1: Find the least common denominator of $\frac{5}{10}$, $\frac{3}{16}$, $\frac{3}{8}$.

Solution:

2)	10	16	3
5)	5	8	3
8)	1	8	3
3)	1	1	3
	1	1	1

$2 \times 5 \times 8 \times 3 = 240$. Ans.

Example 2: Find the least common denominator of $\frac{5}{9}$, $\frac{8}{12}$, $\frac{3}{18}$.

Solution:

3)	9	12	18
3)	3	4	6
2)	1	4	2
2)	1	2	1
	1	1	1

$3 \times 3 \times 2 \times 2 = 36$. Ans.

To reduce two or more fractions to fractions having a common denominator:

RULE (4). *Divide the least common denominator by the denominators of the given fractions and multiply both terms by the quotient.*

Example: Reduce to fractions having a common denominator:

$\frac{4}{10}$, $\frac{6}{10}$, $\frac{9}{10}$.

Finding the least common denominator:

Digitized by Google

5) 10 40 20
2) 2 8 4
2) 1 4 2
2) 1 2 1
1 1 1

$5 \times 2 \times 2 \times 2 = 40$, the common denominator.

Dividing the least common denominator by the denominator of the first fraction, $\frac{4}{10}$, gives

$40 \div 10 = 4$.

Multiplying both terms of $\frac{4}{10}$ by 4, gives $\frac{16}{40}$

Similarly, $\frac{6}{10}$ gives $\frac{24}{40}$, and $\frac{9}{20}$ gives $\frac{18}{40}$

$\frac{16}{40}$, $\frac{24}{40}$, $\frac{18}{40}$. Ans.

ADDITION OF FRACTIONS.

To add fractions:

RULE (5). *Reduce the given fractions to fractions having the least common denominator, and write the sum of the numerators over the common denominator. When there are mixed numbers and whole numbers add the fractions first, and, if their sum is an improper fraction, reduce it to a mixed number and add the whole numbers with the other whole numbers.*

Example 1: Find the sum of $\frac{3}{7}$, $\frac{14}{49}$, $\frac{2}{7}$.

The least common denominator is 49.

Reducing the fractions to this common denominator: $\frac{21}{49}$, $\frac{14}{49}$, $\frac{14}{49}$. Adding the numerators:

$$21 + 14 + 14 = 49$$

Placing 49 over the common denominator $\frac{49}{49}$, or 1. Ans.

Example 2: Find the sum of $2\frac{4}{11}$, $1\frac{7}{22}$, $4\frac{1}{2}$.

Add the fractions first; their least common denominator is 22. Reducing the fractions to this common denominator: $\frac{8}{22}$, $\frac{7}{22}$, $\frac{11}{22}$. Adding the numerator: $\frac{26}{22} = 1\frac{4}{22}$. Adding the whole numbers:

$$2 + 1 + 4 + 1 = 8\frac{4}{22}$$ Ans.

Electrical Instruments and Testing.

Every one connected with the telegraph and telephone service should know how to test lines and also be familiar with the instruments used in such work. It does not require much study to learn the mechanical operations of this important branch of the service, but of course a knowledge of electrical and mechanical principles involved in the design and construction of the instruments, and of the principles involved in measurements is the source of deep and never-ending pleasure to the ambitious student.

An excellent book on this subject, intended for the practical man, is "Electrical Instruments and Testing," by Norman H. Schneider, with new chapters on testing wires and cables and locating faults, written by Jesse Hargrave, division superintendent of the Postal Telegraph-Cable Company, Atlanta, Ga.

This work tells how to use the voltmeter, ohmmeter, ammeter, potentiometer, galvanometer, the Wheatstone bridge and standard portable sets. The apparatus described is modern and in universal use, and the tests are such as are required daily.

Mr. Hargrave carries the student step by step through the different methods of testing for faults, insulation and conductivity, cable faults, etc., and the simplest language possible is used. The formulas given are explained in the text preceding them, and examples are worked out in simple arithmetic.

This is one of the most practical and useful books on electrical testing instruments and testing that has been published and is fully illustrated with views and diagrams of instruments used in this line of work. Every one who desires to widen his knowledge on electrical matters should have a copy of this book in his library. Even if he never has the opportunity to make an actual test he will learn a great deal from the work that will improve his mind and general knowledge of things electric.

The price of this book is $1.00 and copies can be had of TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

Maver's American Telegraphy.

The new and enlarged edition of Maver's "American Telegraphy and Encyclopedia of the Telegraph," known as the 1909 edition, is probably the most complete text-book on telegraphy which has ever been written. Among the important additions to the work in this edition are descriptions of the Barclay Long Distance Printer, as operated on the lines of the Western Union Telegraph Company, and the Murray Printer, as now used in Europe. This book is a library on telegraphy, simultaneous telegraphy and telephony, on wire and cable testing, etc. It is used as a text-book and a book of reference in many of the largest universities, and the large telegraph and telephone offices in this country. It contains within its covers a complete elementary treatise on electricity and magnetism, primary and storage batteries, line construction, etc. The beginner may successfully peruse his studies of these subjects by means of this book without reference to any other work. This statement is attested to by many successful telegraph and telephone engineers who gratefully term the book their Alma Mater. The book is written in simple English, and is practically without mathematics. No aspiring student in the telegraph or telephone ranks can afford to be without it. This fine work will be sent to any address, carrying charges prepaid, on receipt of price, $5.00, by J. B. Taltavall, Telegraph and Telephone Age, 253 Broadway, New York.

Mr. H. J. Jeffs, district traffic superintendent, Western Union Telegraph Company, San Francisco, Cal., in renewing his subscription for another year, writes: "I thank you for renewing my subscription, and wish to add that you deserve credit for the quantity and quality of reading matter, which the TELEGRAPH AND TELEPHONE AGE is now serving its subscribers. It is becoming more interesting each year."

Recent Developments in Radio-Telegraphy.*

BY PROF. G. W. O. HOWE.

During the last two or three years the number of radiotelegraphic installations has increased enormously both on land and sea. This increase has not been due so much to any new discovery or striking improvement as to several instances in which radiotelegraphy prevented what might otherwise have been terrible calamities at sea.

The total number of ships of the mercantile marine fitted with Marconi apparatus at the end of 1907—that is, after seven years of development—was 140; at the end of 1908 the number was 220; at the end of 1909 it was 330; while at the close of last year it had risen to 510. In addition to the mercantile marine, practically every ship in the British navy has been fitted with the Marconi apparatus.

The Telefunken Company of Berlin carried out 106 installations last year, bringing the total number of stations using its apparatus up to nearly 1,000. About 500 of these are warships, principally German and Russian, while 100 are portable military sets. Excluding German boats, only thirteen ships of the mercantile marine are fitted with Telefunken apparatus.

Marconi's earliest experiments were made in 1895-6; and now, after fifteen years, every passenger ship of any magnitude has its wireless installation as a matter of course. There is every indication that very soon practically every ship will be so equipped. Some of the trawlers of the North Sea fishing fleet have recently been fitted with Telefunken apparatus, with a range of 100 miles. These boats receive the weather reports sent out daily from the coast stations, which are thus able to warn the fleet of approaching storms.

The nature of the telegraphic service which may be required of a station is widely varied. A station may have to work with only one other station and never send to or receive from any other. This is practically the case with the transatlantic stations. A station may work with a limited number of stations of definite and well-known characteristics, as in the case of the mailboats running between England and the Continent. On the other hand, a station may have to correspond with all comers.

One can easily see that apparatus which might be eminently suitable in one case would be very unsuitable in the other. Stations in the first category can use uncommon wave-lengths, and thus free themselves, to a large extent, from interference from other stations, besides being able to use a large amount of power without causing interference.

If it were possible for every station and every ship to have a different wave-length, interfering stations might be tuned out to a certain extent, but for the sake of uniformity and convenience in working, the majority of stations have about the same wave-length, so that when one is tuned to receive the desired message, one is also tuned to the disturbing stations. The result is that one station tries to shout the other down, and the successful working of all the stations is greatly hindered.

Apart from all this, there are the atmospheric disturbances, which vary widely from time to time. When a station is receiving from another station at a distance of 1,000 miles, it will certainly "pick up" every lightning flash over a large part of the earth's surface. These atmospheric disturbances are often strong enough to make working impossible over any but very short distances, even when the weather conditions locally look ideal. Whether one can receive or not in spite of the atmospheric disturbances depends on the nature and loudness of the signals, so that one can become more and more independent of the atmospheric conditions by increasing the power employed, and by making the signals easily distinguishable from the sounds caused by the disturbances.

Recent developments in the sending apparatus have been largely directed towards obtaining freedom from interference. This has been sought in two ways: firstly, by sending out well-sustained trains of waves of one definite frequency, thus permitting sharper tuning; secondly, by giving the signals a high musical pitch, easily distinguished from the crackling noises caused by atmospheric disturbances, and also from other stations having notes of a different pitch. The spark gap must be so designed that these characteristics are retained when very large powers are employed. A gap may give excellent results when the power is small, but fail entirely when the power is increased. Absolute reliability and constancy are of far greater importance than efficiency, although any improvement in the latter is naturally to be welcomed, not so much for the saving of power as for the reduction in size and cost of the apparatus.

Quenching of the spark was discovered in 1906 by Prof. Max Wien, and was afterwards taken up by the Telefunken Company, which has evolved a form of spark gap, in which the quenching is very effective. The gap acts as a very quick acting minimum current cut-out, and opens the primary oscillating circuit at the first opportunity—viz., when all the energy has been transferred to the aerial. The time during which the two circuits are coupled is very short, the loss in the spark gap is reduced, and the major portion of the energy oscillates freely in the aerial, and is radiated as a damped train of waves at its natural frequency. In this way it is claimed that seventy-five per cent of the output of the alternator is transferred to the aerial.

Turning now to the receiving apparatus, we find that the filings coherer has practically disappeared. The reception of the signals is now always aural. The detectors now employed in conjunction with the telephone receiver are not much more sensitive than the filings coherer operating a Morse inker, but they enable the operator to discriminate between the signals being sent to him and the various disturbances picked up by the aerial, which, as we have already seen, is a matter of ever increasing importance.

*Abstract of paper read before the British Association for the Advancement of Science, at Portsmouth, England, September 4.

Digitized by Google

The magnetic detector used by the Marconi Company is ideal in its simplicity and reliability, but is not so sensitive as the electrolytic or the mineral-contact detector. The Telefunken Company has recently given up the electrolytic detector in favor of a detector of the latter type. Another type of detector used to a certain extent is the Fleming valve, which combines extreme sensitiveness with comparative simplicity and reliability.

To produce a musical note of high pitch it is necessary to make the sparks follow one another rapidly and with great regularity. When sending at a speed of twenty words per minute, the duration of a dot will be about one-twentieth of a second, so that with a spark frequency of thirty per second the dot will consist of one or, at the most, two sparks, whereas with a spark frequency of 1,000 per second the dot will consist of fifty sparks. The former was quite enough to actuate a filings coherer, but would merely cause a blow on the telephone diaphragm, whereas the latter would give a short piping note in the receiver.

By increasing the alternating supply voltage or by shortening the spark gap, a large number of sparks can be made to occur during each half cycle, but they will occur too irregularly to produce a musical note, unless steps are taken to make the sparks occur at regular intervals. This can be done by replacing the stationary gap by two disks revolving at high speed, the rims of the disks being provided with projecting knobs, between which the sparks jump.

One of the most recent developments, although hardly yet beyond the experimental stage, is the introduction of the telephone relay. By placing one of the telephone relays, recently invented by S. G. Brown, between the detector and the telephone receiver, signals which are otherwise quite inaudible can be easily read. The Telefunken Company has recently experimented with an apparatus somewhat similar in principle and known as a tone-augmenter.

The distances over which communication can be maintained with a given supply of power depend on the height and size of the aerial, on the nature of the intervening country, and on the type of detector employed. A safe guarantee, under very unfavorable conditions, is about fifty miles per kilowatt of alternator output, but, with favorable conditions and sensitive apparatus, distances of over 500 miles per kilowatt have been covered.

Practically all the radio-telegraphic apparatus working commercially or being installed at the present time is based on the principles here considered; with the exception of the spark gap and the detector employed, the differences are non-essential.

Telegraph Facilities at Trial of McNamara Brothers in Los Angeles.—Special telegraph facilities have been provided at the trial of the McNamara brothers in Los Angeles, Cal., on the charge of dynamiting the Los Angeles *Times* building a year ago. A room has been prepared in the Court House for the accommodation of operators, newspaper correspondents, artists, etc.

Mr. M. A. Cosio, Director-General Mexican Telegraphs.

Mr. Miguel A. Cosio, lately appointed director-general of the Mexican Federal telegraphs, with headquarters in the City of Mexico, has had a long and interesting career in the telegraph and telephone services in that country, although his early training was of a military character. He was born in the city of Toluca, Mexico, May 2, 1855, and received his military education in the military college of Chapultepec, and took part in the assault upon the citadel in 1871. Giving up his military career he entered the service of the Mexican Railway in the City of Mexico and advanced rapidly, becoming chief of various important offices along the line.

In 1878 he entered the service of the Federal telegraphs as chief of the Vera Cruz office, and in 1882 was appointed inspector of the lines of the peninsula of Yucatan, later occupying a similar post in the Northeastern section of the Republic.

In 1884 he was commissioned as chief of the general warehouses of the telegraph department and in 1885 returned to the post of inspector. From this time he filled several important posts until July 8 of this year when he was appointed to his present position.

Mr. Cosio has also filled the positions of professor of telegraphy in the military college of Chapultepec and accountant in the school annex of the General Direction of Telegraphs.

The White House on Wheels.

President Taft is a great traveler and when he is away on his frequent trips he makes things hum for the telegraph and the telephone. His special train is a fully equipped business institution, and carries representatives of a great variety of vocations — telegraph and telephone operators, mail clerks, reporters, secretaries, etc. When he stops en route to make speeches the telegraph and telephone feel the effects of his remarkable activity.

Two Viewpoints of Farming.—Recently we received in one day two requests, one from an operator to change his address because he had left the telegraph service to engage in farming, which he thought was more remunerative. The other was from an old telegrapher who had tried his hand at farming for several years and concluding that there was nothing in it said he proposed to return to the telegraph for employment.

Telegraph Monument.—The design submitted by Signor G. Romagnoli, of Bologna, Italy, for the International Telegraph Union Monument, to be erected at Berne, Switzerland, to commemorate the founding of the Union, has been selected by the international jury. The monument will cost 170,000 francs ($85,000). Three of the minority members of the jury have entered a protest against the award.

The Passing of the Old.

There is a touch of pathos in a recent letter from Mr. D. H. Fitch, of Cazenovia, N. Y., who looks back with pleasure and pride upon the old days of the telegraph.

He laments the loss of many of his old time associates and no longer sees any familiar names in the pages of the AGE. All is changed to him.

"I am a back number," he says. "I was with the Western Union when its eastern boundaries were Buffalo and Pittsburgh. I was for nearly twenty years a Western Union district, or railroad telegraph superintendent. I had an extensive acquaintance, and some friends among telegraphers. I turn page after page of the AGE and see no familiar names. Where are J. H. Wade, Judge J. D. Caton, Gen. Anson Stager, J. D. Reid, J. J. S. Wilson. E. P. Wright, Geo. T. Williams. J. F. Wallick. T. B. A. David, Charley Weir, Nate Hucker, Yank Sullivan, Toppy Craig, Payne and others? 'Time touched them and they perished.' And now one of my earliest and best friends, Col. Clowry, has had to give way to more modern, if not better methods. I see words in your paper which I do not know the meaning of, and diagrams which look to me like maps of Hades. Homesick, I close its pages and take the paper down to the library, where it will benefit the young and not haunt me any more."

Mr. Fitch is one of the active old-timers and a few points regarding his career will no doubt be interesting at this time.

He learned telegraphy on the "Utica and Oxford Morse Magnetic Telegraph Line" which was in the territory of the late James D. Reid. "We never had a message," he says, "unless someone was sick or dead, except the 'D. H.' which we used to send for the stage drivers. Each operator had a pair of climbers, equally well adapted to flying or climbing, and was required to keep the line repaired to the next office north. Operators were nabobs in those days. At Utica, one morning, I paid four dollars stage fare to Norwich. At Hamilton we stopped for dinner, and I went over to the telegraph office. When I returned the stage agent asked me if I was a telegraph operator. I honestly believed I was and told him so. He refunded the fare and apologized."

Much of the time in 1861, '62 and '63 Mr. Fitch was engaged on river cables and military telegraph work, though yet employed by the Western Union company. He supervised the construction of the line to and put the first telegraph wire into the St. Louis Arsenal in May, 1861, then commanded by Captain, afterwards General, Lyon. While at St. Charles he had charge of transportation on the North Missouri Railroad which of course included military transportation. He resigned December 31, 1864, and returned home, exhausted and sick.

In the spring of 1865 he went with Captain Geo. H. Smith to the sixth district, Central Division, which then embraced the oil region of Pennsylvania, and in 1866 was appointed Mr. Smith's successor as superintendent and remained there until the district was discontinued and annexed to others. While superintendent of this district he originated the "Map and Scale" tariff.

In 1869 Mr. Fitch was superintendent of telegraph on the Missouri Pacific Railroad, and afterwards on other roads. On the Brunswick and Western Railroad in Georgia, in 1884, he was also general passenger and freight agent.

From 1885 to 1892 he manufactured open-circuit batteries, and sold the business to New York manufacturers.

Soon after the expiration of the Bell patent, Mr. Fitch, in 1894, established the Cazenovia, N. Y., exchange, which was probably the first of the independent exchanges. In July, 1902, he sold the exchange to the Cazenovia Telephone Company and has since been its electrician.

[Mr. Geo. T. Williams is living in retirement in Cleveland, Ohio; Mr. J. F. Wallick, at Indianapolis, Ind., and Mr. T. B. A. David at Pittsburgh, Pa. Mr. Nathaniel Hucker is still in telegraph harness at Buffalo, N. Y., where he has been located since 1847.—Ed.]

The New President of the Old Timers.—In a recent letter from Hon. Wm. S. Jordan, of Jacksonville, Fla., the newly-elected president of the Old Time Telegraphers' and Historical Association, that gentleman expresses his appreciation of the honor as follows: "I am glad to hear that the Atlantic City meeting was such an interesting one and I certainly feel especially honored at having been elected president, and that this City should be chosen for the convention in 1912. We are looking forward to your coming, and shall do everything in our power to make your visit a pleasant one."

Mr. W. S. Jordan, of Jacksonville, Fla., president of the Old Time Telegraphers' and Historical Association, has appointed the following as the executive committee in charge of the affairs of the association for the ensuing year: Charles M. Holmes, manager, Western Union Telegraph Company, Gilbert D. Ackerly and Wm. F. C. Fellers, of Jacksonville, Fla.; Wm. T. Gentry and G. W. Ribble. of Atlanta, Ga.

Great Northwestern Election. — The annual general meeting of the shareholders of the Great Northwestern Telegraph Company was held at Toronto, Ont., September 27, when the following directors were elected and officials appointed: Mr. H. P. Dwight, president; Mr. Adam Brown, vice-president. Other directors: Messrs. W. M. Matthews, James Hedley, Hon. J. K. Kerr, K. C.; Aemilius Jarvis, F. B. Hayes, Toronto; Messrs. Newcomb Carlton and J. B. Van Every, New York; Mr. George D. Perry, general manager; Mr. A. C McConnell, secretary and auditor; Mr. D. E. Henry, treasurer.

Instruction Course in the Elements of Technical Telegraphy.

There apppears to be a general need and demand among telegraphers throughout the country for simple and plain instruction in technical telegraphy, so as to enable them to better understand the apparatus they work and handle daily, and fit them for higher positions.

To meet this demand we have prepared a course of instruction in technical telegraphy, the publication of which began in the October 16 issue of TELEGRAPH AND TELEPHONE AGE. It starts with arithmetic, and carries the student through the work by easy stages, one step following another in natural order.

The mathematics employed are of the simplest character and do not extend beyond elementary algebra. They are given for the benefit of those who may have allowed their knowledge of arithmetic and algebra to become clouded through disuse.

This course will be the most valuable educational matter ever placed before the fraternity. It was prepared as a regular $25.00 course, but it will be free to all subscribers of TELEGRAPH AND TELEPHONE AGE. A liberal installment will appear in each issue.

Some of the subjects covered besides arithmetic and algebra are: Potential, Current, Resistance; the Gravity Battery; Ohm's Law; Wire Resistance; Fall of Potential; Derived Circuits; Battery Arrangement; Magnetism; Electro-Magnetism; Self-Induction, the Induction Coil, the Relay; the Sounder; the Key; the Morse Circuit; Switches; Single circuits in bad weather; Static induction; Testing at terminal stations; Earth; Contact; Swinging faults; Weather contact; Wire Testing at Intermediate Offices; the Detector; Weston instruments, the millianmeter; the Volt-Meter, and a chapter on wire patching.

In addition to all this review questions will be printed at the end of each chapter and the student will have to study the original articles to enable him to answer the questions. This is the most simple and effective method of acquiring a technical telegraphic education and the plan has received the heartiest commendation from high telegraph officials and experts.

Everyone interested should see that this matter is brought to the attention of those who desire to better their condition.

Further information may be obtained of Mr. J. B. Taltavall, publisher, TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

Mr. W. B. Eddy, an old time telegrapher and now in the telephone service at Albany, N. Y., in renewing his subscription, writes: "Reading TELEGRAPH AND TELEPHONE AGE seems next to a personal visit with many of my life-long friends among the telegraph fraternity whose names are frequently mentioned. Now that the telephone is combined it will still be of greater value to me."

New Books.

Practical Telephone Handbook and Guide to Telephonic Exchange. By T. S. Baldwin.

This book contains chapters on the use of the telephone, line construction, line materials, locating and correction of faults in lines and instruments, besides much other information of value to promoters, builders and managers of rural telephone lines. It is written in popular language and covers the field of telephony very thoroughly. The book is well illustrated. Price $1.00 per copy.

Operators' Wireless Telegraph and Telephone Hand Book. By Victor H. Laughter.

A complete treatise on the construction and operation of the wireless telegraph and telephone, including the rules of naval stations, codes, abbreviations, etc. The principal systems of wireless telegraphy are described and altogether this book will be found an excellent aid in the study of the art and practice of wireless telegraphy and telephony. It is profusely illustrated with views and diagrams of instruments, etc. Price $1.00 per copy.

Vest Pocket Electrical Dictionary. A practical hand book of reference containing definitions of electrical terms and phrases in use in every branch of electrical science. It is especially valuable to telegraphers and telephonists, and will be found a great aid in understanding electrical apparatus and applications of electricity in general. Price 50 cents per copy.

"Modern American Telephony in All Its Branches," by Arthur Bessey Smith. A very complete and up-to-date work on the subject of telephony. It has over 800 pages and nearly 600 illustrations. Price, $2.00 per copy.

Electrician's Operating and Testing Manual. By H. C. Hortsman and V. H. Tousley.

This work gives practical instructions for the management, operation and testing of the more important electrical devices now in use. It deals principally with electrical machinery and apparatus and contains much information of general value to the student of telegraphy and telephony. It is free from higher mathematics and is written in plain, easily-understood language. Liberally illustrated and substantially bound in flexible leather. Price $1.50 per copy.

These books and any others on electrical and kindred subjects, published in America or in foreign countries, may be obtained of TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

"A Postal operator" writes: "I have read the description in your issue of September 16 of the new Postal switchboard and the 'questions and answers' regarding it in your issue of October 1 and I am free to say that I have received more enlightenment on this subject from these two articles than I could have received in any other way. I feel quite thoroughly posted on standard switchboard practice through this clear presentation of the subject."

Telephones in England and the United States.*

BY T. F. PURVES, OF LONDON, ENGLAND.

(*Concluded from page 638, October 1.*)

All telephone engineers are at the present time keenly interested in the subject of automatic exchanges, and we did not fail while in America to see all that there was to be seen in that direction. The main idea of automatic working is to reduce the working costs of exchange services by enabling a subscriber to obtain the connection he requires by his own action and without the necessity for employing operators, but improvement in speed of service is also claimed. Each telephone instrument is provided with a mechanical calling device by means of which the person desiring to speak can, in a very simple manner, transmit the number of the party wanted.

In some systems this calling device includes a series of small levers, each of which is pulled forward to a position corresponding to one digit of the number to be signalled. In other systems it consists of a simple rotatable dial with ten numbers, 0 to 9, marked around its periphery, and a call for any number is sent in by turning the dial to zero from the position corresponding to each digit in the number successively. The signalling of each digit sends in a train of electrical impulses which actuate selecting and connecting mechanism at the exchange and so effect connection with the wanted line. The original conception of such a system is now over twenty years old and is generally ascribed to Mr. Strowger. During the past five or six years great strides have been made both in designing and perfecting automatic systems and in establishing working installations. At the present time there are not less than 250,000 telephones working through automatic exchanges in the United States. More than 95 per cent. of these are on the Strowger system, and the remainder are the product of other companies whose engineers have devised systems both notable and effective.

Semi-automatic systems are also pushing themselves to the front. For semi-automatic working a subscriber only requires an ordinary common battery telephone. The attention of an exchange operator is gained in the usual way by lifting the receiver, and the automatic mechanism is set in motion by the operator. She receives the required number verbally from the calling subscriber and taps it out on sets of numbered plungers; the machines do the rest. The speed at which the operator can handle calls in this way is far greater than is possible on an ordinary manual switchboard, where she has to connect the calls through by means of plugs and cords, and to test and ring on the wanted line.

The actual selecting mechanism for semi-automatic exchanges is practically identical with that used on full automatic systems.

As a rule automatic exchanges include also a system of warning signals to attract the attention of the attendants to any failure of the apparatus to perform its functions properly, and means have also to be provided for obtaining connection to trunk circuits and other exchanges, manual or automatic, in the same area. Indeed, there are a good many simpler things to be found on this planet than an automatic telephone exchange.

Up to the present the great Bell companies in America—the companies whose engineers have shown the way to the world in the construction of manual exchange switchboards—have refused to touch automatics, and have consistently maintained a keenly critical attitude with regard to them. All the development of automatic working which has taken place has been in the systems of independent companies. At the present moment the independent telephone company in Chicago—the Illinois Tunnel Company—is installing an automatic system for 80,000 subscribers in eight exchanges of 10,000 lines each. All these exchanges will be inter-connected and work together as a single unit. The apparatus equipment is planned on a basis which will permit of the ultimate extension of the system to practically one million lines.

As already mentioned, the Bell companies are not yet converted to the automatic system, nor do they admit that the public can be expected to handle the automatic telephone successfully. But they have apparently now reached the stage of admitting that the exchange portions of the apparatus, at any rate, promise to work satisfactorily, for they have commissioned the Western Electric Company to work out for them a semi-automatic system. This system is now working in New York in an experimental form. The installation only includes 500 lines, but it is designed on a plan that will provide for ultimate extension to serve nearly two millions of inter-communicating subscribers, whose lines may terminate in, say, 100 exchanges of 20,000 lines each. So the needs of the largest cities for many years to come are being fully kept in mind.

The semi-automatic system which the Western Electric Company has designed is on an entirely original and novel plan and is a miracle of ingenuity. It can readily be adapted to the requirements of full automatic working, and the company's engineers have, in fact, a scheme fully matured for this purpose. Its system, in either of its forms, is bound to be a formidable competitor with other systems in the struggle which may ultimately be expected to result in the survival of the fittest.

The Post Office has now determined to make a trial of automatic exchanges in this country. The first move will be to "try it on the dog," by having an installation to serve as the official switch system at the General Post Office, and it will not be long before two or more systems are working in public exchanges also. It is only in this way that it can be ascertained whether the British public will take kindly to such devices. So far as

*From "The Post Office Electrical Engineers' Journal," London.

Digitized by Google

America is concerned, we took every available opportunity of getting at the attitude of the public. We visited many subscribers who are connected both to the automatic system and to the competing manual system of the Bell companies, and I am bound to say that in the great majority of cases we have found a decided preference for the automatic. Of course the crux of the question is —Will the automatic be cheaper to instal and work than the manual system? Will it enable rates to be reduced to the public? If so, its success is assured. There is naturally a big saving in the elimination of operators, but against that has to be set increased cost for skilled mechanics for maintenance, and probably more rapid deterioration of the apparatus. If it should prove that there is no appreciable difference in cost, I for one should prefer to keep on with the manual system. I think it is much better as a general social proposition to pay operators for doing positive useful work than to spend the same amount in paying men to hunt for faults in complicated mechanism, and to cure trouble after it has arisen. All the same, I believe that in one form or another automatics have come to stay.

The development of "farmers' lines" is a distinctively American product, and is largely due to the initiative of the people themselves, who had contructed a great many lines in far out-lying country districts before the telephone companies had made the discovery that there was a big revenue to be derived from the cultivation of such rural services. Some very weird productions were to be found among the lines built by the farmers in the earlier days. An extra long post in the snake-fences here and there, with a bit of fencing wire strung along on broken bottle necks spiked to the top of them, to serve as insulators, was all that was wanted to put ten or a dozen farmers into useful communication with one another. Now the lines are a little better constructed, but to a great extent the farmers still build them for themselves. Many firms of telephone suppliers all over the country cater for their wants. Each telephone has a powerful hand generator, and the calls reach all the parties on the line. A code of signalling has therefore to be arranged, so that each may know when he is wanted, and when the number of parties on a line is more than six a system of combinations of long and short rings is used. Of course, everyone can overhear his neighbor's business if he wants to; it has even been said that this is one of the main reasons for the popularity of the system!

With all its quaint associations the farmers' line is still a splendid thing for rural America. It has wonderfully mitigated the loneliness of life in the small farms that are dotted about over so many thousands of square miles, and in every way it has brought great business benefits to the farmers as well.

Of the many things we saw and admired in the telephone world of America, there is none that impressed me more than the quality of their organization, the statesmanlike ideas which underlie it, and the hearty way in which all appear to believe in it and to support it. This organization is typical of general American methods, and to it much of the national success is due. Its three fundamental ideas are reasonable specialization, devolution of responsibilities, and direct co-operation between officers whose work is associated. One of the most salient points of the American organization to an engineering man is the broad-minded definition given to the word "engineering." The chief engineer of the American Telephone and Telegraph Company has under him "traffic" engineers as well as "plant" engineers, and is thus able to deal effectively with the development and requirements of the services as a whole, and to formulate standards of construction and of operating practice in proper relationship with each other, for the instruction and guidance of all the associated Bell companies, and of the wide telegraph interests which are also under his control. These telegraph interests were formerly restricted to the leasing of "private wire" circuits superimposed on the long-distance telephone lines, but they have recently been greatly extended by the practical acquisition by the American Telephone and Telegraph Company, of the Western Union Telegraph Company, with its cable system and extensive inland telegraph business. The amalgamation was, I believe, largely due to recognition of the benefits which would result from the co-ordination of the two services, and the best methods of doing so are now being actively studied.

The value of regular statistics is much appreciated in America as a means of supervising the working of large commercial organizations of all kinds, and the greatest attention is paid to framing them systematically on lines which will yield the essential information required by controlling officers. The telephone companies are no exception in this respect. We were informed that the leading ideas in organizing statistical methods are, first, that no man shall be asked to furnish statistics which are not of practical use to himself in gauging the success of the work for which he is responsible, and, second, that the system of standard records shall be so complete as to avoid, to the utmost possible extent, any necessity for calling upon the staff to interrupt their normal duties for the compilation of special returns. The records pass through many hands and many processes of refinement, useful at each stage, before they ultimately reach the heads of the company in a shape which enables the working of every important branch of the business to be reviewed in terms of the all-important criterion—dollars and cents.

The apparent harmony with which all classes work together in the American services is striking. Two or three times I commented on this, and the reply in each case was to the same effect —"Employ high-grade men and there will be no friction."

INDUSTRIAL NEWS.

Electrical Measuring Instruments.

Messrs. Foote, Pierson and Company, New York, have recently put upon the market a new improved switch set, which is very compact and designed for quick and accurate work. It consists of a Wheatstone bridge, rheostat, battery and galvanometer keys, special switches for short circuiting these keys, and switch and binding posts for ground connection.

The switches, contacts, etc., are mounted on a polished rubber plate, and are contained in a polished mahogany case, making a very handsome as well as serviceable instrument.

The rheostat comprises four arms—10 units, 10 tens, 10 hundreds and 9 thousands, and "open,"

IMPROVED MEASURING INSTRUMENT.

making a total of 10,110 ohms. These resistances are arranged in series, having a zero contact at the beginning of each set.

The bridge arms consist of three coils of 10,100 and 1,000 ohms, so arranged that in connection with the rheostat the set will measure from 0.01 ohm to 1,011,000 ohms. The resistance is varied by means of three-leaf switches moving over platinum-faced contacts.

Catalogue No. 26, issued by the firm, gives complete information regarding the line of electrical measuring and scientific apparatus manufactured and sold by it. The illustrations are particularly clear and are accompanied by diagrams showing details, connections, etc.

A Telephone Train Dispatching System Paralleling a High Tension Transmission Line.—The New York, Westchester and Boston Railroad is now installing telephone equipment which is particularly interesting because of the fact that it is the first installation of a telephone train dispatching system paralleled by high tension, single-phase circuits. The telephone system will be complete, consisting of train dispatchers' circuits and message wire circuits of various kinds. All the circuits, with the exception of the train wires, will be provided with intercommunicating features. As this road is electrically operated on 11,000-volt, 25-cycle, single-phase circuits, it was decided to make the distribution system of underground cable. The layout for the complete telephone system had to be designed for future extension and to afford good transmission through considerable cable. The dispatcher's office will be located at the 180th St. Station, New York, as will also the message operator, who will monitor the various message circuits and have charge of the local telephone service through a special switchboard. The complete equipment was furnished by the Western Electric Company.

Useful Telephone Booklet.—The Kellogg Switchboard and Supply Company, Chicago, Ill., has issued a booklet entitled "Things Telephone Users Should Know About Telephone Systems and Service." The pamphlet explains in non-technical language the different kinds of telephones, their construction and use so that anyone may become more familiar with the instrument and its operation, and the information given will no doubt go a great way toward making friends for the telephone. The booklet is written by Mr. H. N. Faris, who has had a long and wide experience in the practical telephone field.

Western Electric Company's Business.—The statement of the Western Electric Company's business during August shows a falling off in gross sales of three per cent as compared with the sales of the same month in 1910. Although four out of the last five months have shown a decrease in gross business, the falling off has been so slight that the increase in the first three months is sufficient to make the whole eight months that have elapsed show a gain of three per cent over the corresponding eight months of 1910. The company has 26,000 employes on its payrolls.

Fifteen Thousand Feet of Cable Manufactured in Two Days.

In making 15,000 feet of 100-pair lead covered cable in two days the Western Electric Company recently set a new record. The hurricane which swept over Charleston, S. C., last month left that city isolated from the rest of the world, as far as communication was concerned. The Southern Bell Telephone Company made such heroic efforts to put its plant in operation again that service was resumed in a remarkably short time. More lead covered cable was needed, however, and the telephone company called up the Atlanta office of the Western Electric Company and placed an emergency order for 15,000 feet of 100-pair cable. The Atlanta house immediately wired the company's cable plant at Hawthorne, Ill. Two days later this 15,000 feet of cable was on its way. In two days nearly three miles of 100-pair cable had been manufactured, placed on huge reels and shipped.

Mr. I. N. Sharpnack, manager, Western Union Telegraph Company, Parkersburg, W. Va., in renewing his subscription for another year and changing his address to his house, writes: "I have no time to read the paper at the office. The AGE makes the fireside brighter."

How News Is Transmitted to Daily Papers on Atlantic Steamers.

Under the caption "Journalism at Sea," the September *Marconigraph* gives an interesting description of the Cape Cod, Mass., station, and how the news is transmitted to and received by steamers at sea for publication in the daily papers issued on board.

Every day in the year at 8.30 p. m. a special despatch is prepared at the Associated Press office in New York and telegraphed direct to the Marconi station at Cape Cod, South Wellfleet, Mass. From here, by means of wireless telegraphy, the world's news is sent out to vessels hundreds of miles distant on the Atlantic. The aerial wires supported by the masts of each steamer intercept a sufficient number of the ether vibrations sent out by the Cape Cod transmitter to operate the sensitive receiving apparatus, the operator records the message, and in the morning the traveler finds the news that has come so far and has been printed while he slept.

The plant of the Cape Cod station is about two miles from the railway station at South Wellfleet, Mass., and is situated directly on a sand bluff that overlooks the Atlantic Ocean.

Four huge towers, each two hundred and fifteen feet high, support a network of copper wires, the lower ends of which lead into the transmitting room. These wires, when charged, set in vibration the ether for fifteen hundred miles around. Under the shade of these towers nestle the several buildings containing the plant. A low brick structure houses the great engines and humming dynamos that furnish the necessary power for the transmission of messages to great distances. Under the same roof is also located a large storage battery and a machine-shop. Connected to this building by a long corridor are the transmitting and operating rooms, in which occur the wonderful display of electrical pyrotechnics that has caused the plant to be dubbed "Marconi's thunder factory."

About a thousand feet from the plant is situated a comfortable bungalow that shelters the men employed at the station. There is a plank walk from the plant to the house and many are the tales told of trying to keep to the path on a stormy night when the ground is covered with snow and the air full of blinding sleet, or of endeavoring to reach the bungalow when a fierce wind is blowing that drives the loose sand against the men's faces with such force as almost to draw blood. On one occasion during a heavy storm the manager became confused in attempting to make the passage from the house to the plant and only succeeded in reaching his destination by following the wire fence which encloses the grounds for its entire length.

The staff consists of a manager, two telegraph operators, two engineers and two old salts as riggers, a chef and steward, and two dogs. The manager is the technical man and wireless engineer of the plant, in addition to his position as head of the family. The two telegraph operators take shifts in working the land lines and wireless circuits, for this station is also used for communication with Boston shipping. The engineers stand watch on alternate nights to start the main engines and to keep them running smoothly. There are also a thousand and one things for them to do during the day—some repairing, improvements to be made or experiments for the engineer at the head office in New York. The riggers keep the towers and stays in ship shape.

There are various tasks to engage the men during the daytime, but it is at night that the real work of the station begins. At 8.30 p. m. the operator on duty hears a call on the land line, and he is at once busy copying on his typewriter the news despatch from the Associated Press. He then takes his copy down to the plant and starts punching the strip. This operation is one recently added to the daily régime, and is the means by which the entire news message is sent automatically in perfect Morse characters without the operator touching a key. In order to ensure the receiving of the message by the ships at sea, many of which are at distances too great to ask for repetitions of certain words they may have missed, the entire news despatch is repeated several times. In the days when the operator must needs send this long message four times by means of a huge telegraph key, in addition to receiving it from New York over the land line, the news became rather a bore, especially when the hours of the morning were small and the man's eyes heavy for sleep. The message having been punched on the paper, the strip is then wound on a reel attached to the motor-driven automatic transmitter, and is then ready for the programme, which starts at 10 o'clock each night and continues until completed.

At 9.30 the engineer on watch hastens down from the dwelling house to the plant and starts three great flaming torches, in order to heat the ignition balls of the kerosene engines. Oil engines are used in this plant because of the high cost of coal and the difficulty of delivering it at the station. By 9.50 o'clock all is in readiness—the engines are running and the recording instruments are inspected to note whether the current value is correct. When the clock points exactly at ten a red signal light flashes in the engine room, the operator releases the catch on the automatic transmitter and the crashing noise of the spark is immediately heard in the adjoining room. Here in the transmitting room great streams of fire a foot long are thrown out by powerful blowers and the tremendous noise of the spark, though musical, is terrifying. Very few persons have seen this plant in operation, for visitors are strictly prohibited from entering upon the premises, but one may hear the high-pitched note of the powerful spark for several miles if the night be quiet or the wind favorable. Through the windows of the station the spark has been seen for fifteen miles at sea. Viewed from the exterior, the intense white flash showing through the ground glass windows of the instrument room and the deafening crash of the spark would cause one to believe that here is the home of the Evil One. In this way the great plant is calling to ships near and far, and sending them the news of the day. The ships may

Digitized by Google

be fifteen hundred miles or only one hundred miles away, and, unless the vessel is at the greater distance, the operator usually copies the complete despatch correctly the first time without recourse to the repetitions that follow.

While the operator at Cape Cod is busy sending out the day's despatch, on each one of the numerous ships on the broad Atlantic there listens an attentive ear.

Between the masts of each vessel are strung horizontally several stranded copper wires about the diameter of a pencil. These wires are separated by wooden spreaders and carefully insulated by special hard rubber insulators from the masts and their attendant stays. Several vertical wires are connected at the centre of the horizontal ones, and these lead directly through an insulator into the wireless cabin, usually located on the upper deck. Here are the special and sensitive instruments in which we are particularly interested. This room is especially constructed with sound-proof walls, several inches thick, and lined with cork. These more modern accommodations are in marked contrast to the quarters on the older vessels with which the operators had to content themselves.

Each night, a few minutes before ten, the operator in charge shuts himself in the little sound-proot room, provides himself with pad and pencil, adjusts the pair of telephone receivers to his head and awaits the stroke of ten. Exactly on the minute, the faintest little whisper is heard in the telephones. The giant spark at Cape Cod is saying, "Good evening, ships, good evening, ships." These signals, though somewhat faint, are quite distinct, and may be likened to the gentle purring of a contented kitten, though they are not so loud.

Quite recently it has been discovered that the human ear is more sensitive to a higher musical note than that which was produced by the spark formerly in use, which was at the rate of four thousand sparks per minute. The new musical spark has a frequency of thirty-six thousand impulses per minute, and is readable at considerably greater distances with the same power. In the meanwhile, with receivers tightly pressed against his ears, the operator is rapidly writing down pages of news. This continues for about an hour, at the end of which time the despatch is complete. The copy is then quickly transcribed on the typewriter and hurried down to the "editor on board" of the *Atlantic Daily News*.

When the copy is ready it is turned over to the typesetter, who prepares the type in the good old way in vogue in newspaper offices before the advent of the linotype machine. By long practice he has become very deft, and in a short time all is complete and passed over to the printer for his part of the work. The forms are rapidly adjusted to the motor-driven press.

The first wireless newspaper to be published on board a vessel crossing the Atlantic was a little sheet known as the *Transatlantic Times*. It appeared November 15, 1899, and was published on board the American line steamer "St. Paul," *en route* for England. On this voyage the St. Paul carried Mr. Marconi and two of his engineers, returning from America, where they had been carrying on experiments with a new kind of telegraphy. The particular object of their visit had been to report the yacht races for the Associated Press, and as success had crowned their efforts, they were looking for new worlds to conquer. They decided to publish a newspaper on board ship, and obtained the latest news of interest from the Marconi station at The Needles. The papers were neatly printed, and were sold at a dollar a copy for the benefit of the Seamen's Fund. From this small beginning the idea gradually grew until the erection of high power stations at Cape Cod and Poldhu made possible the constant reception of news from land and a daily issue.

The *Atlantic Daily News* is a paper of from eight to ten pages, and is printed in the form of a magazine. On the outside cover there is a copy of some famous painting, a photograph of some prominent man, or an illustration of some article within. There are many items of interest in the paper, news from all parts of the globe, the quotations of the Stock Exchange, the latest gossip of the sporting world.

The papers are most eagerly sought after by the passengers, and they are scanned with absorbing interest. It is the great event of the day on shipboard, and conversation turns to the facts that have been made known by the advent of the little sheet. Of course, the barest facts are all that can appear in news despatches that aim to send as much information as possible in as short a form as is commensurate with making sense.

For the last five years newspapers have been published daily on the Atlantic liners. From the individual efforts of the steamship companies, each of which printed its own paper with its own title, has developed a publication with an issue of several thousand copies daily, with a single management for all the lines.

Free Lectures on Electricity.—The Department of Education of New York City has arranged for the usual free lecture service during the winter months. Prof. W. Wallace Ker, of the Hebrew Technical Institute, will give a course both in Manhattan and Brooklyn on the principles and practice of electrical engineering. Other lectures will be on elementary electrical science, by Messrs. J. Newton Gray, Frederick W. Huntington and Charles L. Harrington and Prof. John S. McKay.

Substitute for Platinum.—Owing to the limited supply of platinum there is a pressing demand for a substitute, especially in electrical work. The principal source of supply is Russia. A little platinum is produced in this country as a by-product in placer mining. A fortune awaits the man who succeeds in inventing a substitute for this precious metal, and here is an opportunity for our readers of an inventive turn of mind to make their mark in the world.

KERITE

INSULATED WIRES and CABLES

DEPENDABLE

Kerite Cables installed upward of 35 years ago, and exposed to deteriorating influences, are giving perfect service to-day.

EFFICIENT

Kerite does not rely upon the rubber in its composition for insulating efficiency. Kerite itself is a compound having superior insulating qualities.

SERVICE

A half century of successful service has demonstrated that Kerite possesses the essential qualities of safety, reliability and economy to an exceptional degree.

The Railroad.

Educational Meeting of Pennsylvania R. R. Telegraphers.—About one hundred telegraphers and other employes of the telegraph department of the Pennsylvania Lines east of Pittsburgh and Erie, held their monthly meeting in Buffalo, September 23. Mr. J. C. Johnson, of Philadelphia, superintendent of telegraph, presided and Dr. R. H. Hough, of Philadelphia, read a paper on technical problems.

Telephone Train Dispatching on Atlantic Coast Line.—The Atlantic Coast Line Railroad, W. P. Cline, superintendent of telegraph, which has had for some time 167 Gill selectors in service in its telephone train dispatching and message service, has received from the United States Electric Company, New York, 98 additional Gill selector equipments, which are being installed in extension of the system to Jacksonville, Fla.

Reading Telegraph Company Meeting.—At the annual meeting in Reading, Pa., on October 2, of the Philadelphia, Reading & Pottsville Telegraph Company, which is a subsidiary of the Philadelphia & Reading Railroad, and works in connection with the Western Union Telegraph Company, the following officers were elected: President, George F. Baer; secretary, H. E. Paiseley; treasurer, W. R. Taylor. Mr. C. M. Lewis, Reading, Pa., is superintendent of telegraph.

Telephone Train Dispatching on the Toledo and Ohio Central.—The Toledo and Ohio Central Railroad, which recently adopted the telephone for dispatching trains on its eastern division, has recently placed another order with the Western Electric Company for thirty-one telephone selectors for use on its western division. This new circuit will extend from Columbus, where the dispatcher will be located, to the Union Station at Toledo, a distance of 132 miles. When both circuits are completed the Toledo and Ohio Central will be operating 280 miles of track by telephone.

Baltimore & Ohio Adds over 300 Miles of Telephone Train Dispatching Circuits.—The Baltimore and Ohio Railroad has recently placed an order with the Western Electric Company for eighty-five of its selectors for use on five new circuits. Between Rockwood, Pa., and Johnstown, Pa., a distance of forty-five miles, there will be two circuits, each equipped with nine stations. One circuit will be used for train dispatching and the other for an intercalling message circuit. The dispatcher for both circuits will be located at Rockwood.

There will also be a train circuit running from Newark, Ohio, to Cambridge, Ohio, a distance of fifty-two miles. Between these two points another train circuit will be run as an open circuit, and from Cambridge to Bernwood Junction, Ohio, there will be installed fifteen selector equipments. The total distance of the line will be 105 miles. The dispatcher for both of these circuits will be located at Newark.

In addition, an intercalling message circuit will parallel the train wires running from Newark to Bernwood Junction, a distance of 105 miles. The dispatcher for this circuit will be located at Newark, and twenty-eight stations will be equipped.

Telephone Dispatching on the Cincinnati, Hamilton and Dayton.—The Cincinnati, Hamilton and Dayton Railroad has recently placed an order with the Western Electric Company for seventy-nine of its telephone selectors and associated telephone apparatus to equip three new circuits. One circuit will extend from Indianapolis, Ind., to Hamilton, Ohio, a distance of 99 miles, and on it twenty-one selector station equipments will be installed. The dispatcher will be located at Indianapolis. The second circuit will extend from Dayton, to Cincinnati, Ohio, a distance of sixty miles, and will be equipped with twenty-four station outfits, the dispatcher being located at Dayton, and the third circuit will extend from Dayton, Ohio, to Toledo, Ohio, a distance of 140 miles, with thirty-four stations. The dispatcher for this circuit will also be located at Dayton.

B. S. Jenkins, Superintendent of Telegraph, Canadian Pacific Railway.

Mr. B. S. Jenkins, general superintendent of the Canadian Pacific Railway Telegraphs, Western Lines, is the subject of an interesting personal sketch in the *Manitoba Free Press*, of Winnipeg, Man. Mr. Jenkins has just completed thirty years' continous service with the company, during which time he has been prominently identified with the railway company's telegraph system.

Mr. Jenkins was born at Richmond Hill, Ontario, April 8, 1859, and entered the service of the Canadian Pacific Railway, September 21, 1881, as operator at Boniface Junction, opposite Winnipeg. In July 1883, he was appointed superintendent of telegraphs covering the western dvision of the Canadian Pacific and in December, 1899, was made general superintendent of telegraphs of the company's western lines, from Port Arthur to the west coast of Vancouver Island. Mr. Jenkins, it is stated, is the senior telegraph official of the system, and is one of the leading citizens of Winnipeg.

Federal Ownership of Telegraphs.—Congressman W. B. Francis, of Ohio, appeared before the National Good Roads Congress, held in Chicago recently, and advocated Federal ownership of telegraph lines along public highways, the highways to extend across the continent and north and south. He proposed that the revenues from the telegraph system be used in keeping the roads in repair.

Mr. J. W. Atkins, manager of the Western Union Telegraph Company at Key West, Fla., on being told that we had renewed his subscription for another year writes: "I wish you to do the same thing yearly."

Dispatching of Trains by Telephone*.

BY W. W. RYDER, GENERAL SUPERINTENDENT OF TELEGRAPH, NEW YORK CENTRAL LINES, CHICAGO, ILL.

The usefulness of the telephone in place of the telegraph as a means of communication between railway stations was early recognized, and in fact, on some roads the telephone was used in the handling of trains as early as 1883, but it was not until the fall of 1907 that the telephone was used exclusively for such service on a busy main line. In October, 1907, the New York Central established a telephone dispatching circuit between Albany and Fonda, N. Y., a distance of forty-six miles, and the Chicago, Burlington and Quincy made a similar installation between Aurora and Mendota, forty-five miles, the following December.

Success was evident from the start, and other roads becoming interested have adopted the practice, until now about 36% of the entire railway mileage in the United States is so operated. The following figures, taken from the Government report of January 1, 1911, show the extent to which some of the principal railroads had adopted this method of dispatching:

New York Central Lines	3,966
Santa Fe	3,884
Great Northern	3,881
Illinois Central	2,550
Burlington	2,383
Rock Island	2,248
Pennsylvania	2,137
Northern Pacific	1,190
Norfolk & Western	1,066
St. Paul	1,044
Total operated by telephone	24,349

Now let us consider some of the reasons for this remarkable growth, or, in other words, the real advantages gained by this substitution.

First is the aid to the dispatcher in that his work is handled more easily as well as more expeditiously. By reason of the quickness with which communications may be passed, he is able to keep up his train sheet in better shape than ever before and with much less actual physical effort. Also the same fact of quickened transmission relieves the tendency of condensing or restricting information which might be of great value if given, but which, with the telegraph, was often omitted because of the time it took to spell out letter by letter every word and figure of such information. The dispatcher is also able, whenever he so desires, to talk directly with the conductor or engineer, and is thus able to secure a more accurate knowledge of the actual details than was ever possible through the use of the telegraph. Also his attention in case of emergency can be much more promptly secured than is possible with the use of the telegraph.

Another advantage is the promptness with which operators respond to their calls. In telegraph practice, a call for any one office is heard with equal clearness in all the other offices on the circuit and is not always immediately answered by the operator desired, even when his attention is finally attracted. During this time the telegraph wire cannot be used for any other purpose than the calling. With the telephone the call consists in the ringing of a large vibrating electric bell in the particular office wanted and is not heard in any other office; consequently, when once these bells begins to ring, anyone within hearing knows that particular office is being called. As a result, operators answer more promptly and the time of the dispatcher, consumed in the constant repetition of the telegraph call, is saved. It is also possible to put out a call on the telephone circuit while a conversation is in progress.

Another important improvement is the fact that the telephone works much better in wet, foggy weather than does the telegraph, and experience has also demonstrated the fact that it will work during storm prostrations where the telegraph, under similar conditions, would be absolutely inoperative. The telephone also works better in territory where inductive disturbances from trolley lines and high tension power circuits interfere with the operation of the telegraph, and these conditions are rapidly multiplying.

With the use of the telephone it is possible to provide satisfactorily for communication to and from blind sidings and it makes possible oftentimes, the closing of unimportant offices for a portion of the day or night where heretofore telegraph operators were required chiefly for possible emergencies. Telephones are so placed at such offices that the conductor can get in direct touch with the dispatcher if necessity requires.

The train and engine men are in favor of the change, for they recognize that it helps get them over the road more promptly, minimizing the delays on side tracks waiting for the dispatcher to get time to move them. They also realize the benefit of being able personally to talk over with the dispatcher the little matters that are constantly arising that affect train movement. In fact, the spirit of harmony and co-operation between dispatchers, operators and train and engine men has greatly increased since the telephone has brought them into closer personal touch and with corresponding gain in efficiency and discipline.

The telephone is also rapidly replacing the telegraph in the handling of way-office messages, it having been found possible to handle from 50 to 75% more business over a way telephone circuit in a given time than is possible with a similar telegraph circuit. This, of course, means more prompt service, and a further postponement of the necessity for increasing facilities.

Summarized in a few words, the advantages in the use of the telephone for dispatching and other division work, are that it is quicker, safer and

The Best Selector

you can buy is the GILL SELECTOR of the United States Electric Company.

Wherever decision has been governed by competitive service tests, the GILL SELECTOR has been adopted.

No other is so efficient or so low in maintenance expense.

New York **Chicago**

New Book on Telephony.

A new book entitled "Modern American Telephony in All Its Branches," by Arthur Bessey Smith, will be ready for delivery in October. It will contain over 800 pages and nearly 600 illustrations, and will be the most complete and up-to-date work on the subject. The price will be $2.00 per copy. Address TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

Telephonology

The New Telephone Book

Contains 16 chapters covering every branch of telephony.

Comprises 586 pages full of valuable information for every one interested in the telephone.

Has 700 illustrations of up-to-date apparatus and circuits.

Written for the practical telephone man, who has no time to study theory, but who is looking for practical instruction "how to do" things.

Tells how to locate and remedy trouble, line, instrument and switchboard.

How to make simple testing equipment and to use it.

All modern systems—both Magneto and Common Battery described and illustrated.

The whole subject is thoroughly covered, from the theory of magnetism to automatic and wireless telephony, including composite, harmonic and selective lockout systems.

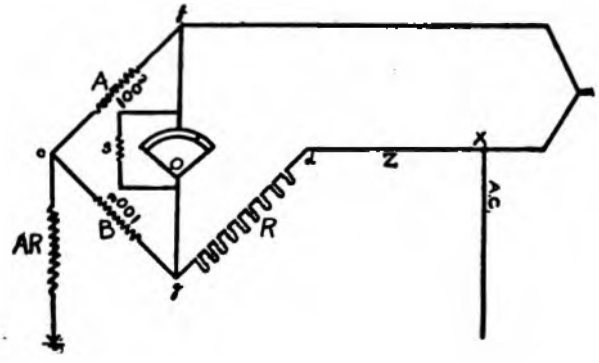
more reliable, more flexible, and in addition makes possible better discipline and co-operation between the dispatcher and operators, as well as providing means for officials who are not familiar with the Morse code to obtain immediate and accurate information in cases of emergency, and thus be in better shape to exercise personal supervision.

Test for Locating Alternating-Current Crosses.

BY A. J. EAVES, ELECTRICAL ENGINEER'S OFFICE, POSTAL TELEGRAPH-CABLE COMPANY, NEW YORK.

The accompanying diagram shows the connections of a method for locating alternating-current crosses on telegraph lines:

Disconnect the battery wires at *c* and *d* of a Wheatstone bridge set and ground the point *c* through a resistance *AR* sufficient to reduce the incoming alternating-current below the danger point, and then substitute for the galvanometer an alternating current mil-ammeter, shunted with about 10 ohms resistance, *s*, as a protection to the instrument. Balance the bridge by inserting resistance in the rheostat *R* until the needle points to zero, on the lower scale of the mil-ammeter, which indicates that no current flows between *f* and *g*. Then half of the



LOCATING ALTERNATING-CURRENT CROSSES.

resistance of the rheostat *R* will be equal to the distance in ohms from the point the crossed wire is looped with the good wire to the alternating current cross, if the two wires are of approximately the same resistance.

To determine the distance in miles from the test station to the cross, make a loop measurement of the good and crossed wires before the battery wires are disconnected from the bridge and use the Varley formula:

Where M = Length of loop in miles.
O = Resistance of loop in ohms.
R = Resistance of rheostat when bridge is balanced.

$$Z = \frac{O-R}{2}$$ = Resistance from testing station to cross.

Then the distance in miles from the test station to the cross is

$$X = \frac{Z \times M}{O}$$

By using a telephone receiver instead of an alternating current mil-ammeter the same result can be obtained by inserting resistance in the rheostat *R* until no noise, or a minimum noise, is heard in the receiver.

The Telephone in the German Army.

While the telegraph was used extensively in warfare for many years, the telephone is of more recent use in that connection, and its great value in directing the movement of large bodies of men was first demonstrated in the Russo-Japanese war. The German army has furnished all its troops with telephone equipment, enabling them to be in constant speaking communication even with the foremost outposts in the field. Every large command or division has a special telephone corps attached, which consists of trained telephone men under the comman of a sergeant, who is also a telephone man. All of the men are mounted, and the necessary equipment is taken along on trucks. Each division of this corps can lay four miles of telephone lines and equip four stations with the material on hand, taking about 20 minutes to lay 0.6 miles. These men are to establish communication between the troops in battle, the artillery and the staff commanders, as also between the staffs of the different army corps. The infantry is also provided with a special body of men, called the infantry telephone corps. This part of the service is only a new department and has not advanced very far as yet. But the idea is to equip each infantry company with such a small division and with a telephone outfit. The instruments are made in such a way that they can be carried by the men in the troop and that communication can be established in the least possible time between the outposts and the main body of troops.

The artillery carries this equipment on a special gun carriage, and the modern method of warfare in which artillery firing is done from protected positions and directed by the commanders at some distance back of the danger zone, makes the telephone one of the necessities for preserving life and obtaining an effective fire.

With the cavalry each regiment has a telephone patrol consisting of eight men and a sergeant with telephones and four miles of wire and supplies of wires are carried along on a truck. In this way all of the troops are equipped with telephones permitting rapid and efficient communication at all times.—*Telephone Engineer.*

Mr. F. C. Hackett, former manager of the Western Union Telegraph Company at Cleveland and Toledo, Ohio, and elsewhere, now in other business, in renewing his subscription says: "Even though I am out of the active telegraph service, I look forward with great pleasure to receiving my copy of TELEGRAPH AND TELEPHONE AGE twice a month."

Meeting of Western Union Managers in St. Louis.

A meeting of the managers of most of the important offices in the second district, Western Division, of the Western Union Telegraph Company, was held in St. Louis, September 20, in the office of district commercial superintendent W. R. Chapman, the object of the meeting being to discuss informally matters of general interest to the telegraph service, enable the managers to become better acquainted with one another and avail themselves of the benefits that result from an exchange of ideas as to methods which obtain at their respective offices. The relationship between the telegraph and telephone companies, new system of auditing, methods of soliciting, courtesy of employes, etc., all came in for discussion, and the various new forms now being used by the telegraph company, and which are meeting with such favor, were carefully considered and explained.

Every manager agreed that the meeting had been most helpful in every way and had inspired them with a determination to spread out in every direction from the routine in which they had fallen.

After the business session, which lasted five hours, the party was entertained at an elaborate luncheon at the Mercantile Club, followed by a theatre party at the Columbia Theatre.

In addition to district superintendents W. J. Armstrong and W. R. Chapman, chief clerk Callahan of the commercial department and special agent Edwards, those in attendance were: R. H. Bohle, St. Louis; G. W. Brownson, Kansas City, Mo.; J. A. Crawford, St. Joseph, Mo.; E. C. Newton, Little Rock, Ark.; H. L. Arnold, Hot Springs, Ark.; H. C. Stannard, Fort Smith, Ark.; E. M. Haldeman, Texarkana, Ark.; E. A. Rippey, Springfield, Mo.; R. J. Volker, Jefferson City, Mo.; F. E. Gibbons, Sedalia, Mo.; W. Elrod, Carthage, Mo.; O. O. Horner, Helena, Ark.; J. B. McLeod, Jonesboro, Ark.; E. R. Potter, Fayetteville, Ark.; H. E. Johnson, Poplar Bluff, Mo.; F. W. Hoyler, Pine Bluff, Ark.; J. H. Napier, Moberly, Mo.; C. McNeill, branch office manager, St. Louis.

The greater number of managers who attended the meeting left for home on the night train, but several remained to talk over matters peculiar to their respective localities.

A message received from division commercial superintendent M. T. Cook explained that owing to important business matters, which had just come up, it would be impossible for the division officials to be present as was expected. He expressed a hope that the meeting might prove a success and wished the managers an enjoyable time.

Dominion Telegraph Company.—The assets of the Dominion Telegraph Company of Canada according to the recent annual report, were $1,310,530 and the liabilities $1,016,860, leaving a balance of $293,670. Following are the officers and directors for the current year: President, T. Swinyard, vice-president, Sir Henry M. Pellatt, secretary-treasurer, F. Roper; other directors, B. Brooks, T. F. Clark, R. C. Clowry, Æ. Jarvis, C. O'Reilly and A. G. Ramsay.

Poles Purchased in 1910.

A preliminary statement showing the number of poles purchased by the telephone and telegraph, steam and electric railroad, and electric light and power companies in the United States during the years 1910, 1909, 1908 and 1907, has been issued by Census Director E. Dana Durand, Washington, D. C.

Of the 3,870,694 poles purchased during 1910, 2,831,810, or 73.2 per cent., were reported by telephone and telegraph companies, and 305,792, or 7.9 per cent., by steam railroad companies. The number reported by the telephone and telegraph companies, however, was slightly less than in the preceding year, the decrease amounting to 84,195.

While 28 different woods were reported as drawn upon for pole material during 1910, four species—cedar, chestnut, oak and pine, ranking in the order given—contributed more than 90 per cent. of the total during each of the four years covered by the report. Among the woods used in relatively smaller quantities as pole material a marked decrease is noted in the case of cypress.

An interesting fact disclosed by the figures is the rapid growth of the practice of treating poles in order to prolong their period of use.

More Efficient Men Wanted.

Hundreds of telegraph engineers have gained their electrical knowledge by studying International Correspondence Schools Courses while traveling between their homes and offices. It takes only a few minutes of close application each day during spare time to lay the foundation and build up an excellent knowledge of the higher branches of the telegraph and telephone professions. In this age of specialization, it is necessary to have more than a general knowledge of a subject. It is the man who has trained himself in all the details of some one subject who is in demand and who secures the renumerative positions.

The International Correspondence Schools' Telegraph and Telephone Engineering Courses have been compiled by the best authorities in the country and comprise the best instruction in existence in modern telegraph and telephone practice. Full and careful treatment has been given to the subjects of switchboard connections, single line and multiplex repeaters, duplex and quadruplex systems, simultaneous telegraphy and telephony, dynamos, storage batteries, the testing and construction of bare-line and cable circuits, etc.

If those wishing to increase their knowledge along any of these or other electrical lines will write to the International Correspondence Schools they will mail you, without cost, complete information covering the various Courses.

Address, International Correspondence Schools, Box 885, Scranton, Pa.

The Turner Monument Fund.

The bronze tablet for the Turner monument, an illustration of which was published in our issue for October 1, has received general commendation, and is characterized as a highly artistic piece of work. It reflects great credit upon the sculptor, Mr. Charles Keck, of New York. Mrs. E. H. Harriman, of Arden, N. Y., has generously provided for the stone work and the construction of the monument.

Mr. Charles T. Ford, of Central Valley, N. Y., superintendent of the Harriman estate, is supervising the stone work and is an enthusiastic worker for the success of the monument project.

As the time for the dedication approaches, those who have not yet contributed to the fund should take the matter up before the close. Everyone interested in the railroad in any capacity should consider it a privilege to contribute toward this worthy cause, however small the amount may be.

Mr. J. B. Taltavall, 253 Broadway, New York, is treasurer of the fund and will be glad to hear from anyone who wishes to be identified financially with this worthy movement; all contributions are acknowledged in the columns of TELEGRAPH AND TELEPHONE AGE. The amounts received up to date aggregate $1,675.49, and it is desired to increase the fund as far as possible so as to insure a fitting ceremony at the unveiling next month at Harriman, N. Y.

Mr. E. P. Griffith, superintendent of telegraph of the Erie Railroad, chairman of the committee, expects to soon issue the dedication invitations. Mr. Henry D. Estabrook, of New York has been selected as the orator on the occasion of the unveiling. He has a national reputation as a speaker of unusual ability and having been identified with telegraph interests for over a quarter of a century is well qualified to perform this interesting duty.

Mr. Andrew Carnegie has promised to be the final contributor to the fund.

Meeting of T. M. B. A.—The annual meeting of the Telegraphers' Mutual Benefit Association will be held at 4 p. m., November 15, at 195 Broadway, New York. An amendment to the constitution providing that past presidents shall be members of the executive committee will be voted upon and also an amendment making change in date of annual meeting.

LETTERS FROM OUR AGENTS.

PHILADELPHIA POSTAL.

Mr. F. E. McKiernan of the New York office was a recent visitor.

The great telegraphic song hit, "SEND ME A NIGHT LETTER, DEARIE." Good, catchy music; beautiful title design magnificently printed in colors. Title contains night letter. Sung all over New York, 17c. by mail. All popular music sent by mail.

B. L. BRANNAN,
195 B'way, N. Y.

Mr. P. C. Murphy, formerly stationed at the *Telegraph* office, is now at the switchboard, and Mr. Brandt of this office is looking after our interests at the *Telegraph*.

NEW YORK WESTERN UNION.

Mr. J. F. E. Hopkins, lately of the Eastern Board, has been appointed division loop chief in place of Mr. Willis H. Jones, who has been attached to the staff of Mr. W. E. Athearn, engineer of equipment.

Miss Jennette F. Powell has resumed duty after spending the Summer at Saratoga Springs, N. Y.

Mr. M. J. Olwell, formerly of this department, accidentally fell out of a window at his home in this city on October 5 and was instantly killed.

The annual entertainment of the New York Telegraphers' Aid Society for the benefit of the Relief Fund will take place on Tuesday evening, November 21, at the Lexington Ave. Opera House, Fifty-eighth Street near Third Avenue, Manhattan. Mr. James P. Clolery has been appointed chairman for this season and announces that the members of the various committees are making every effort to bring this year's event up to the standard and if possible surpass previous entertainments.

The Telegraphers' Mutual Benefit Association, 195 Broadway, New York, enables telegraph and telephone employes to provide for their families life insurance in reasonable amounts, at a cost so low as to be within the reach of all. It has already paid beneficiaries of deceased members $1,500,000, at an average annual cost per $1,000 of about four cents a day, and has also accumulated $327,000 Reserve Fund securely invested, to provide against excessive cost in the future. Membership is easily acquired and cannot be invalidated during life for any cause except failure to pay the necessary mortuary calls.

An Interesting Letter.—Mr. A. L. Suesman, of Oak Bluffs, Mass., has facsimiles of an interesting letter from General Thomas T. Eckert to Fred Catlin. A copy may be obtained by sending four cents in stamps to Mr. Suesman.

Martin's double or single lever **VIBROPLEX** $7.50. D. C. DeLany, 15 S. Broad St., Atlanta, Ga.

TRANSMITTING MACHINES

I am placing on the market improved YETMAN TRANSMITTING TYPEWRITERS, and KEYBOARD TRANSMITTERS without typewriting features. Am prepared to exchange, repair or rebuild all old machines. Write for catalogues and particulars to

James Uncles, NORTH ADAMS Massachusetts

Rubber Telegraph Key Knobs.

No operator who has had to use a hard key knob continuously should fail to possess one of these flexible rubber key caps, which fits snugly over the hard rubber key knob, forming an air cushion. They render the touch smooth and the manipulation of the key much easier. Price, fifteen cents.

SOME POINTS ON ELECTRICITY.

BY WILLIS H. JONES.

Loops, Cords and Springjack Defects—A Hint to Linemen.

(*Continued from page 664, October 16.*)

Flexible cords which usually from the main line terminals of branch office loops probably cause more temporary interruptions to the service than any other part of the circuits, especially after they have been used some time. They should therefore be tested carefully and intelligently the moment intermittent trouble becomes noticeable.

Owing to the flimsy material with which the cord conductors are made, consisting as they do of fine copper tinsel twisted together, and the manner in which they are connected to the brass sides of the wedge, they cannot withstand rough usage very long without becoming a source of trouble. Furthermore, when a defect appears, other than a full break, it is at first so deceptive and elusive that the fault is hard to locate.

For illustration: A few broken strands may not actually break the electrical continuity, but they certainly do cause a high resistance at times, and frequently diminish the volume of current to such an extent that the sounders stand "open." A slight alteration of the position of the cord giving it a different angle usually bridges over small defects of this kind by pressing more strands into service. Even when every strand is broken, the ends sometimes overlap one another, and thus preserve partial continuity until the cord is again shifted or placed at another angle.

Again, with every strand intact, high resistance may result from insufficient pressure against the brass lips of the wedges. Imperfect contact of this kind results from stretching the strands by constant handling of the cords, and thus diminishing the diameter of the small wire rope they form, which is held against the brass by the tape and twine wrapped around the wedge. It will thus be seen that the source of a defect in a flexible cord may in nearly every case be found in or near the neck of the wedge where all the wear and tear occurs.

HOW TO TEST A CORD.

To determine whether intermittent openings are due to imperfections in the cord or the springjack in which it is inserted, first press the upper lip of the jack down firmly on the wedge, so that the latter cannot move, as you twist the cord near the neck so as to give it all possible angles. If the cord is defective at that point your test sounder, which you should insert, will disclose the fault by opening and closing. If the cord is not defective no opening will occur.

The next operation is to remove the hand pressure against the jack and move the wedge sideways in the jack. If openings then occur you should look for trouble in the springjack. If it is the receiving side that shows trouble, the defect will usually be found in a loosened nut behind the board which connects the wire to the under lip.

If it is on the sending side and is caused by a side twist of the wedge the fault probably lies in the hinge pin and can only be remedied by removing the jack and replacing it with a new and better fitting pin.

Sometimes a loop will open when the wedge is inserted too far. This fact usually leads the inexperienced to believe the springjack is defective. In the majority of cases, however, it will be found that the trouble is due to the wrapping twine being too thick near the base of the wedge. This fault is particularly noticeable in old wedges which have been carelessly rewrapped. When such is the case the opening is caused by the diminished pressure of the springjack lips on the brass sides of the wedge owing to their contact now being made principally at the base of the wedge. This base pressure acts as a lever and tends to separate the blades at the tip or at least lessen the contact pressure on the strands, hence high resistance or an apparent "opening."

There are really more openings on duplex loops due to this source than is suspected. In fact probably 50 per cent of the openings reported to the loop chief in one day may be attributed to defects of this nature. When such faults occur the loops may in nearly every case be closed by merely tapping the open side of the loop's wedge with a 70-volt battery. The extra voltage seems to bring a strain on the intertwined strands and causes a bet-

Digitized by Google

ter contact to be made, and, strange to say, the contact is maintained for hours at a time after the regular voltage has been replaced, and sometimes the contact remains permanent.

Of course interruptions of this kind are not usually confined to one loop, but in a large loopswitch a great many are encountered every day. However, when the defect appears two or three times in the same loop, it is advisable to have the wedge rewound at once.

Linemen are too frequently sent on a blind chase because wedge terminals are not tested soon enough. In large offices there are men detailed to repair cords at almost a moment's notice, so there is no excuse in not promptly remedying these defects. In small towns where such help is not available, each manager should learn the way to repair cords properly and see that such work is not neglected. The operation has been accurately described in a back number of this journal, and if the reader does not know how to proceed, it is simply one of many other free lessons missed by those who do not subscribe for this paper.

Recent Telegraph and Telephone Patents.

ISSUED OCTOBER 3.

1,004,767. Combined Telegraph, Signal and Telephone System. To W. A. Froeckman, St. Louis, Mo.

1,004,995. Telephone Instrument. To P. B. Clarke, Liverpool, England.

ISSUED OCTOBER 10.

1,005,179. Guard for Telephone and Telegraph Wires. To C. J. Elliott, Oxnard, Cal.

1,005,194. Telephone System. To T. W. Gleeson, Boston, Mass., and W. H. Gilman, Medford, Mass.

1,005,393. Telephone System. To C. S. Winston and E. H. Rupe, Chicago, Ill.

1,005,714. Cable Duplex System. To I. Kitsee, Philadelphia, Pa.

1,005,715. Telegraphy. To I. Kitsee, Philadelphia, Pa.

Personal.

His Excellency Agap Effendi Stamboulian has been appointed Minister of posts, telegraphs and telephones of the Ottoman Empire.

Mr. E. H. Binford has been appointed superintendent of the Mountain Telegraph Company, with headquarters at Denver, Col., vice J. R. Waltz, deceased.

Mr. D. G. Ramsay, an old-time telegrapher and now a member of the bar at Chicago, is a candidate for election as judge of the superior court in that city.

Mr. Thomas A. Edison.—It is reported from Stockholm, Sweden, that Mr. Thomas A. Edison will be awarded a Nobel prize for his scientific achievements.

Mrs. Marconi.—Signora Marconi, wife of Signor Guglielmo Marconi, the inventor of wireless telegraphy, has been chosen as a lady-in-waiting to Queen Helena of Italy.

Mr. W. D. Weaver, editor of the *Electrical World*, New York, has been appointed a member of the Edison medal committee of the American Institute of Electrical Engineers.

Major George O. Squier, assistant chief signal officer, Washington, D. C., recently gave a lecture at the Franklin Institute, Philadelphia, on "Electrical Methods of Intercommunication for Military Purposes."

Mr. Frank A. Munsey, the well-known publisher, and an old-time telegrapher, has returned from Europe. He was a passenger on the steamer *Olympic* at the time she collided with the British cruiser *Hawke*.

Mr. Gano Dunn has returned from abroad, where, as a representative of the United States Government and as president of the American Institute of Electrical Engineers, he has been attending the International Electrical Congress at Turin and the meeting of the International Electrotechnical Commission.

Mr. Thomas A. Edison was entertained at luncheon on the occasion of the formal opening of the New York Electrical Show on October 11. He was presented with a cubic foot of copper by copper producers as expressing their appreciation for what his inventions have done for the copper industry. The copper cube weighs 486 pounds.

Mr. Ralph W. Pope, former secretary of the American Institute of Electrical Engineers, New York, and an old-time telegrapher, made an address at Great Barrington, Mass., on September 5, on the occasion of the one hundered and fiftieth anniversary of the incorporation of that town. Mr. Pope is a native of Great Barrington.

Capt. W. L. Candee.—The "Brooklyn Eagle" of Sunday, October 8, contained an interesting account of the work of Capt. Willard L. Candee in introducing the telephone in Brooklyn, N. Y., in 1877. The story is well written and includes a portrait of Capt. Candee, who is now president of the Okonite Company, New York.

Mr. George M. Eitemiller, one of the most expert and best known telegraphers in the United States, who has been located at Detroit, Mich., for several years past, has just recovered from a severe illness caused by a nervous collapse. Mr. Eitemiller has lost none of his old time vigor and his beautiful Morse is as clean cut today as thirty years ago.

Mr. J. F. Gormley.—The Canton "Journal," of Canton, Mass., recently printed a portrait and a brief biographical sketch of Mr. James F. Gormley, an old-time telegrapher and now a respected citizen of that place. Mr. Gormley is now seventy-five years of age and retired from active duty after a service of fifty years. He began his telegraphic career as a messenger boy in the early fifties.

Dr. Adolf Franke, director of the Siemens & Halske A. G., Berlin, Germany, who arrived at New York October 13 on a visit to the United States, will represent the "Verband Deutscher Electrotech-

niker" at the Helmholtz celebration, which has been arranged by the American Institute of Electrical Engineers. Dr. Franke is accompanied by Dr. A. Ebeling, chief of the Pupin department of Siemens & Halske Company, and well known among the profession for his researches on, and designs of, Pupin lines and Pupin cables. These gentlemen, accompanied by Dr. K. G. Frank, the American representative of the Siemens & Halske interests, New York, will visit a number of the more important telephone and telegraph installations in this country, and will study especially the effect of high tension transmission lines on telephone and telegraph lines and long distance telephonic and telegraphic transmission in general. Later these gentlemen will be joined by Dr. Paul Rasehorn, chief of the department for measuring instruments of the Siemens & Halske A. G.

Postal Telegraph-Cable Company.

EXECUTIVE OFFICES.

Mr. E. J. Nally, vice-president and general manager, left New York on October 23 on an extended western trip.

Mr. C. P. Bruch, third vice-president, New York, has returned from a trip to Boston and Baltimore on company business.

Mr. L. Lemon, division superintendent, New York, has returned from Buffalo, N. Y., where he went to fill the duties of Mr. H. D. Reynolds, district superintendent at that point during the latter's absence of two weeks.

Mr. Harvey D. Reynolds, district superintendent, Buffalo, N. Y., was a recent executive office visitor.

Mr. Frank G. McGinnis has been appointed cashier of this company at Boston, Mass., vice J. H. Wentworth, deceased. Mr. McGinnis has been in the service about ten years and was appointed assistant cashier for six years.

Mr. Jos. E. Fenn., who has for seven years been in charge of the repeater service for the Postal Telegraph-Cable Company at La Junta, Col., has resigned. It is not stated what plans he has made for the future.

The Jacksonville, Fla., office of this company is to be remodeled and enlarged during the coming winter, and the overhead wires on Bay Street are to be placed underground. Mr. George W. Ribble, district superintendent, Atlanta, Ga., is looking after the details of the work. A new line will also be constructed to De Land and an office opened there.

Western Union Telegraph Company.

EXECUTIVE OFFICES.

Mr. Newcomb Carlton, vice-president; Mr. Belvidere Brooks, general manager, together with general superintendents Mr. A. G. Saylor of New York, Mr. T. P. Cook of Chicago, Mr. H. C. Worthen of Atlanta, Ga., Mr. L. McKissick of Dallas, Tex., Mr. J. C. Nelson of Denver, Col., and Mr. C. H. Gaunt of San Francisco, Cal., met in conference in New York October 16-20 to discuss matters pertaining to company business throughout the country. On the evening of October 18 President Theo. N. Vail and vice-president Newcomb Carlton entertained the general superintendents at dinner at the New York Yacht Club.

Mr. T. W. Carroll, assistant to the general manager, has returned from a business trip throughout the South.

Mr. E. Parsons, district plant superintendent at Indianapolis, Ind., has been transferred to Cleveland, Ohio, to occupy a similar position in that city.

Mr. H. A. Carrell, manager at Macon, Ga., has been appointed city solicitor for this company at Jacksonville, Fla.

Mr. H. D. Spencer has been appointed chief clerk to district traffic superintendent R. W. Kean at Minneapolis, Minn., vice W. G. Pownall, resigned to accept a position as train dispatcher at Bogalusa, La.

The following appointments have been made in the Southern Division by superintendent J. S. Calvert of Richmond, Va,; Mr. Geo. W. Gyles, manager at Bennettsville, S. C., vice Geo. A. Haralson, who leaves the service; Miss Henrietta Hoffman, manager at Marion, Va., vice Von M. Summers; Mr. Von M. Summers, manager at Harrisonburg, Va., vice Miss Ella N. Vollrath, resigned; Miss L. W. Bowden, manager at Rutherfordton, N. C., vice J. H. Carpenter; Mr. J. H. Carpenter, manager at Clinton, N. C., vice H. S. Matthews, who leaves the service; Mr. W. S. Green, formerly operator at the Portsmouth, Va., office, manager, vice Miss C. B. Beall.

At the meeting of the stockholders of this company on October 11 the following directors were elected: Oliver Ames, John Jacob Astor, Union N. Bethell, Henry A. Bishop, Robert C. Clowry, Henry P. Davison, Chauncey M. Depew, Harris C. Fahnestock, Henry M. Flagler, Robert M. Gallaway, Edwin Gould, George J. Gould, Edward J. Hall, Henry S. Howe, Thomas H. Hubbard, Edward T. Jeffery, Charles Lanier, Robert S. Lovett, John J. Mitchell, William H. Moore, J. Pierpont Morgan, Jacob H. Schiff, Joseph J. Slocum, James Stillman, Harry B. Thayer, Theo. N. Vail, Henry Walters, John I. Waterbury, J. C. Willever, Robert Winsor.

At the meeting of the directors on October 18 the executive committee and officers were elected as follows: Executive committee—E. J. Hall, chairman, U. N. Bethell, H. A. Bishop, R. C. Clowry, H. C. Fahnestock, T. H. Hubbard, Jacob H. Schiff, J. J. Slocum, Theo. N. Vail. Officers—President, Mr. Theo. N. Vail; vice-presidents, Messrs. Newcomb Carlton, J. B. Van Every, Thomas F. Clark and G. W. E. Atkins; treasurer, Mr. A. R. Brewer; acting secretary, F. W. Lienau; auditor, E. Y. Gallaher. Over 780,000 shares were represented at the annual meeting.

A conference of traffic superintendents and traffic chiefs of the large offices in the first, third, fourth

Digitized by Google

and fifth districts of the Eastern Division was held at 195 Broadway, New York, on October 24 and 25, and general traffic matters were discussed. Among those present, besides J. A. Hill, division traffic superintendent, New York, were: Herbert Smith, district traffic superintendent, New York; Richard O'Brien, district traffic supervisor, Scranton, Pa.; T. J. Meade, district traffic supervisor, Albany, N. Y.; T. H. O'Mara, general traffic chief, Buffalo, N. Y.; J. M. Lighton, general traffic chief, Syracuse, N. Y.; C. Bauer, general traffic chief, Albany, N. Y.; W. J. Dodge, district traffic superintendent, and J. A. Larimore, general traffic chief, Pittsburg, Pa.; J. M. Creamer, district traffic superintendent, Philadelphia; F. R. Webb, E. A. Anderson and J. W. Collins, general traffic chiefs at Philadelphia, Baltimore and Washington, respectively; L. D. Wilbourn, district traffic superintendent, and J. B. Rex, general traffic chief, Boston, Mass.; T. A. McCammon, traffic superintendent; E. T. Burrill, general traffic chief; J. Morison, assistant general traffic chief; T. Brennan, chief clerk, and C. C. Lever, general wire chief of the general operating department, New York; W. A. McAllister, traffic superintendent, and P. J. Tierney, cable supervisor, cable office, New York; F. D. Giles of the general superintendent's office and H. K. Griffin, eastern division traffic supervisor, New York.

A dinner was given on the evening of October 21 by the plant and traffic employes of the New Orleans office and was well attended. Speeches were made by Mr. W. A. Porteous, manager; Mr. T. P. Cummings, district superintendent; Mr. H. Vandevender, commercial superintendent, and others. The most of the evening was occupied by a chalk-talk lecture on electrical units and co-related subjects by Mr. Louis Casper, superintendent of equipment, after which steps were taken for the formation of an electrical club for the purpose of taking up the study of telegraph and telephone engineering.

The headquarters of this company at Jacksonville, Fla., are undergoing a general renovation and many improvements are being added. The official staff at this point consists of L. J. Maxwell, district superintendent; C. M. Holmes, manager; R. L. Branton, chief operator; J. A. Suder, night chief operator; C. A. Nichols, all night chief operator; E. L. Williams, supervisor of traffic; S. A. Young, supervisor of traffic; S. L. Burts, commercial superintendent. The company employs one hundred and fifty clerks and operators in the summer, and from one hundred and seventy-five to two hundred in the winter season in the Jacksonville office.

Mr. W. H. Mann, manager of the Western Union office at Phoenix, Ariz., believes in familiarizing his force with the apparatus the telegrapher is called upon to handle in the discharge of his duties. He is placing books and trade paper literature at the disposal of the employes of the office.

The Telephone.

Mr. J. E. Farnsworth, vice-president of the Southwestern Telegraph and Telephone Company, Dallas, Tex., was a recent New York visitor.

Mr. F. H. Bethell, of the New York Telephone Company, addressed the Telephone Society of New York on the subject of "Conservation and the Wire Service," at the meeting of October 24.

Miss Kathleen Lyon, the telephone operator at Austin, Pa., who gave the warning by telephone of the approaching flood when the dam burst at that place recently, has been rewarded by the telephone company for her heroism. She received $100 in cash and a gold watch.

Mr. Alfred E. Holcomb, assistant secretary of the American Telephone and Telegraph Company, New York, is the author of a paper entitled "The Assessment of Public Service Corporations," read at the fifth annual conference held at Richmond, Va., September 5-8, under the auspices of the International Tax Association. It is a very exhaustive discussion of the subject.

Telephony in Russia.—A government bill has been introduced to authorize the complete reorganization of the Russian telephone service under the control of the state.

Telephone Rates in Birmingham, Ala.—The petition of the Southern Bell Telephone and Telegraph Company to the Alabama Railroad Commission for permission to increase its rates in the city of Birmingham was dismissed for the want of jurisdiction.

Telephones for Forest Fire Alarms.—The telephone system in the Mount Tacoma, Wash., national reserve consists of fourteen miles of telephone communication. This line was constructed by the Federal government and is a part of a system which later will be much more comprehensive. All of it is located so as easily to connect with rural telephones and thence indirectly with the Tacoma central office.

Independents Absorbed by Bell Telephone Company.—The Auburn (N. Y.) Telephone Company, together with the Skaneateles and allied telephone companies in Onondaga and Cayuga counties, have been sold to the Bell interests through the Friendship Telephone Company. These companies have hitherto been independent and were among the larger components of the system of the Federal Telephone Company.

Telephone Society in Buffalo.—Officers and employes of the western division of the New York Telephone Company, Buffalo, N. Y., have perfected the organization of a telephone society, which has for its object the study of matters pertaining to the telephone business. The local organization is affiliated with the Telephone Society of New York and will be known as the Western Section of the Telephone Society of New York. It will draw its membership from employes of the New York Telephone Company, the American Telephone and Telegraph Company, the Western Electric Company and the

Digitized by Google

Western Union Telegraph Company and their allied interests in Western New York. Meetings will be held once a month. The officers of the society are: Chairman, C. A. Spaulding; vice-chairman, J. L. Parker; secretary-treasurer, Harrison Stewart; executive committee, W. J. Hiss and F. C. Waite.

Telephone Extension in Austria.—The extension of the telephone system in Vienna and throughout Lower Austria is being actively prosecuted. The whole area of the capital city is being equipped with telephone lines and exchanges at suitable intervals, and the work will extend well into next year. Besides the main scheme, a series of block systems will be installed. Outside Vienna and throughout the length and breadth of Lower Austria, the improvement of existing installations and erection of new ones is in full swing.

New York City Telephone Directories.—The compiling of the New York City telephone directories by the New York Telephone Company is done by a department which is devoted exclusively to this work all the year round. The printing and binding is done by one of the largest printing houses in the world, which keeps about 350 skilled workmen busy for eight months in the year. It costs the company $40,000 a year to deliver the directories, and when a new directory is issued all the old ones are collected and ground to pulp at a large paper mill.

Entertainment By Telephone.

The New Jersey Telephone Herald Company, Newark, N. J., on October 24 inaugurated its service for the distribution of news bulletins, music, theatricals, sermons, etc., by telephone, also the correct time. The announcements are made by "Stentors" into special microphones, and there is a fixed hour during the day for every class of news. Under this system a subscriber can hear any of the prescribed forms of entertainment and instruction at stated hours of the day or night without leaving his home.

Radio-Telegraphy.

Mr. Jack Irwin, who won fame as the wireless operator on the Wellman transatlantic airship expedition, will occupy a similar position on the Sieberling-Vaniman dirigible balloon, with which an attempt is to be made to cross the Atlantic.

Navy Wireless Exhibit in New York.—The electrical school at the Brooklyn Navy Yard had an interesting exhibit at the Electrical Exposition in New York October 11-21. The display consisted of wireless telegraph apparatus demonstrating the methods of instructing the navy operators. There was also a panel board working in conjunction with a set of signal lights such as are used on battleships which are used to flash signals between the vessels of a fleet at night.

To Reorganize United Wireless Company.—Stockholders of the United Wireless Telegraph Company have organized a protective committee and will try to formulate a reorganization plan by which the company may be taken out of the hands of the Federal receiver. The committee is composed of G. W. Gray, chairman; John W. Jones, secretary; Orlando P. Dorman, Leroy H. Byam, Dudley McAdow, James Baker and Isaac P. Williams. Stockholders in favor of the movement are requested to send in their proxies to the committee at No. 1 Wall Street, New York.

Cross-Country and Coast Wireless.—The operator at the New York "Herald's" wireless station at the Battery, New York, recently was in direct wireless communication with Sault Ste. Marie, Mich., 825 miles away, also with the battleship "North Carolina" at the Portsmouth, N. H., Navy Yard, 350 miles distant.

The wireless operators at the naval torpedo station at Newport, R. I., recently talked with the naval wireless operator at Key West, a distance of 1,100 miles. Messages from Colon were also distinctly heard at Newport, the distance being over 2,000 miles. New apparatus was used at Newport.

The Cable.

The Tripoli Cable.—Cable communication between Malta and Tripoli has been restored.

Cable Repaired.—The cable steamer "Relay" belonging to the Mexican Telegraph Company effected repairs to the French cable off St. Pierre, Miquelon, during the middle of October.

Argentine Trade Conference.—The first Argentine Trade Conference in the City of New York was held in that city on October 10. Mr. B. H. Reynolds, superintendent of the Central and South American Telegraph Company, made an interesting address on his company's extensive system of communication between the United States and the Argentine Republic, which has been so great a factor in improving the trade relations between the two countries.

The Associated Press.

Col. J. R. Caldwell, representative of the Associated Press in Cuba, has returned to his post in Havana after a visit to the United States.

Mr. Arthur W. Copp has been appointed superintendent of the Western Division of the Associated Press, with headquarters at Chicago, vice Mr. W. E. Kloeber. Mr. Copp was the Denver correspondent of the Associated Press, and is succeeded at that point by Mr. C. C. Hagerty of the Chicago office.

Obituary.

James R. Waltz, superintendent of the Mountain Telegraph Company, Denver, Col., died recently at the age of 35 years.

George A. Deal, aged 37 years, formerly manager of various Postal offices in New England cities, and latterly manager of the Providence, R. I., office of Henry Clews & Co., the New York bankers, died in Providence on October 23.

Meeting of The Telephone Pioneers in Boston.

Following is the official programme for the meeting of the Telephone Pioneers of America to be held at the Hotel Somerset, Boston, Mass., November 2 and 3:

Thursday, November 2.

Morning—Meeting 10 a. m. Organization.

Afternoon—Addresses by Dr. Alexander Graham Bell, Thomas D. Lockwood, and others.

Evening—Theatre.

Friday, November 3.

Morning—Visiting Main Telephone Exchange.

Afternoon—Automobile ride, taking in Concord, Lexington and suburbs of Boston.

Evening—Formal Banquet.

A banquet for ladies only will be served in a special hall and music and entertainment will be provided for them.

The organization committee of the Telephone Pioneers of America has issued a neat booklet containing a list of members. It shows a total of 439 pioneers and is bound in a Bell telephone blue cover, the title being embossed in gold. Twenty-three of the pioneers represent the Southern New England Telephone Company. The committee consists of Messrs. Henry W. Pope, Charles R. Truex and Thomas B. Doolittle, 26 Cortlandt Street, New York.

Over 200 acceptances for the banquet have been received, and these do not include the ladies who will be taken care of independently. The invitations will be handsomely engraved and the names of the pioneers engrossed thereon.

Among the prominent telephone men who expect to be present will be Mr. Frederick P. Fish, former president of the American Telephone and Telegraph Company.

There will be some interesting exhibits. Mr. E. T. Holmes, who is one of the earliest of the pioneers, will show the first telephone switchboard ever used, and the Western Electric Company is getting out a beautiful souvenir of the original telephone as shown in the Bell patents.

Mr. Angus S. Hibbard, of the personal staff of Mr. Theo. N. Vail, has charge of the banquet arrangements and is preparing a programme that will be highly interesting and enjoyable.

Members of the Reception Committee will meet the delegates on their arrival at the various stations.

The automobile procession on Friday, November 3, will, it is stated, be one mile long. Each automobile will carry four pennants showing the seal of the society. As the delegates pass into the automobiles they will be presented with a booklet by representatives of the New England Telephone and Telegraph Company, giving historical information regarding Boston and the surrounding country.

During the banquet on Friday evening portraits of prominent pioneers will be projected upon the screen.

The Western Electric Company has drawn up the plan for the arrangement of the banquet hall. It shows thirty tables, at each of which six persons will be seated. Each person will find a souvenir at his seat. At the front of the room will be a raised platform, at which the prominent members of the association will be seated. This has been termed the "P. B. X."—private branch exchange—and at each table one person will be designated to act as "supervisor."

Financial.

According to the report of president Theo. N. Vail of the Western Union Telegraph Company for the year ended June 30, $80,000 in Mutual Union Telegraph Company 6% bonds were exchanged during the year for a corresponding amount of Western Union 5% collateral trust bonds, which largely accounts for the increase in outstanding collateral trust bonds and the reduction in the outstanding bonds of subsidiary companies. The outstanding holdings of 6% Mutual Union bonds maturing in 1911 were, on June 30, $1,877,000. These bonds were renewed for 30 years at 5%.

The company borrowed $2,000,000 on temporary loan during the year.

On June 30, 1910, the accountants set up a reserve of $2,000,000 against the American Telegraph & Cable Company cables leased by the Western Union Company until 1932, in order that there might be a fund to guarantee their maintenance during the continuance of the contract. There has been the extraordinary expenditure of approximately $800,000 in the course of the year for the renewal of the English shore ends, and there has been added to the fund, by means of monthly charges to operating account, the sum of $135,000, showing a net decrease in fund at the close of the year of $665,000.

To Absorb Western Telephone and Telegraph Company.—The American Telephone and Telegraph Company has announced its intention of absorbing the Western Telephone and Telegraph Company. The deal will be arranged through the purchase of the minority portions of the $16,000,000 preferred and $16,000,000 common stocks. For each four shares of Western Telephone preferred stock will be given three shares of American Telephone and $20 in cash. For each five shares of Western Telephone common will be given one share of American Telephone.

Telegraph and Telephone Stock Quotations.

Following are the closing quotations of telegraph and telephone stocks on the New York Stock Exchange October 26:

Western Union Tel. Co.	77¼
Mackay Companies	86½
" " pfd.	72½
Amer. Telep. and Teleg. Co.	134¼

The Telephone and Telegraph in Tripoli.—Tripoli, which is the centre of the war between Italy and Turkey, has only seven telephone stations. The system is operated by the military department. The country has 3,150 miles of telegraph.

Digitized by Google

QUESTIONS TO BE ANSWERED.

[One of the most effective means of imparting information is to ask and answer questions, the value and power of this method being due to the fact that the information given in an answer is specific and direct. Asking questions for the student to answer for himself has proved to be an excellent means of education, as it promotes and encourages concentration of thought and investigation in order to arrive at the correct answer. There is a general demand for knowledge on the quadruplex, duplex, etc., and to aid in the acquirement of such knowledge we are extending our help to students by asking questions on these subjects in each issue of our journal, so that they may be encouraged in their studies by answering them. We use as our text book Maver, and Davis's "The Quadruplex," and students should have a copy of this book at hand in order to be able to give the answers. The questions are progressive and a careful reading of the book on the points under inquiry unfold the answers. This method of acquiring technical knowledge is a fascinating one.]

CHAPTER IX (*Continued*).

How is the condenser adjusted so that its discharge will equal that of the line?

When the balance is attained how is the fact indicated on the instruments?

If the home polar relay responds to each motion of the home pole changer, is the static balance considered good?

What other method is there to obtain a static balance?

What is the objection to this latter method of balancing?

What is the effect on the operation of the polar side of a displacement of the armature of the polar relay from the "centre"?

Review the third method of adjusting the condenser to the line discharge.

In adjusting for static, why is it advisable to apply the full battery to the line?

Does the whole battery to the line cause a greater or less static discharge than would a half or a third of the battery?

Explain why the static discharge varies with the strength of the current.

What test is made to ascertain whether the static balance at both ends of the circuit is correct?

If B's writing comes clearly under all varying conditions at the A office, what does it indicate?

If the contact points of the distant pole changer should be rough or otherwise defective, what would be the effect at the home station?

How may the contact points of a pole changer be put in proper order?

If cleaning the points of the pole changer does not remove the breaking-up of signals, what is the next step to be taken?

If B's writing comes light on both sides or if B complains that A's writing comes light, what should be done?

If, while B is dotting on his pole changer A is unable to read his signals on the No. 2 side, what directions should be given to B to determine the source of the trouble?

What would be the effect on the operation of the instruments of a defect between the "tap" of B's battery and the post of his transmitter?

What are the possible causes of such a defect?

Suppose the static balance at the A end of the line is not good, what will be the effect?

If varying the capacity of the condenser has no effect on the static discharge what is the probable cause of the trouble?

If another wire is crossed with a quadruplexed wire and is "openod" in order to clear the latter, what is the effect on the static capacity?

It is sometimes necessary to add another condenser to a circuit. Under what circumstances and why is it done?

Does a change in the weather conditions affect the balance of a wire?

A Good Guide.

A Cornell graduate, an electrical engineer, was killed in an accident while following his profession. Among his papers, after his death, was found this statement of what he had set himself to be and do in life. It was headed "My Guide" and it ran thus:

"To respect my country, my profession and myself. To be honest and fair with my fellow-men, as I expect them to be honest and square with me. To be a loyal citizen of the United States of America.

"To remember that success lies within myself, in my own brains, my own ambition, my own courage and determination. To expect difficulties and force my way through them. To turn hard experience into capital for future struggles.

"To believe in my proposition heart and soul. To carry an air of optimism in the presence of those I meet. To dispel ill temper with cheerfulness, kill doubts with a strong conviction and reduce active friction by an agreeable personality.

"To make a study of my business. To know my profession in every detail. To mix brains with my efforts and use system and method in my work. To find time to do every needful thing by never letting time find me doing nothing. To make every hour bring me dividends in increased knowledge.

"To keep by future unmortgaged with debts. To save as well as to earn. To avoid expensive amusements until I can afford them. To steer clear of dissipation, and guard my health of body and peace of mind as a most precious stock in trade.

"Finally, to take a good grip on the joys of life and to play the game like a man. To fight against nothing so hard as against my own weaknesses, and to endeavor to grow in strength as a gentleman."—*Savings Journal.*

Novel Poles.—Tests are to be made at Tucson, Arizona, with a view to utilizing Sahuara (a giant cactus) for telegraph and telephone poles. The government will build a telephone line for the forestry service of the Coronado forest reserve and will fasten the brackets and insulators to the cacti.

CHANGES OF ADDRESS.—In ordering a change of address the old as well as the new address must be given.
REMITTANCES to Telegraph and Telephone Age should be made invariably by draft on New York, postal or express money-order, and never by cash loosely enclosed in an envelope. By the latter method money is liable to be lost, and if so remitted is at the risk of the sender.

November 1, 1911.

The Telephone Pioneers.

TELEGRAPH AND TELEPHONE AGE extends its heartiest greetings on the birth of the Association of the Telephone Pioneers of America, and wishes the new organization a long and useful career.

While it is founded largely on the idea of sentiment and sociability, it will no doubt incidentally serve a more utilitarian purpose. By meeting together at regular periods there will naturally be an exchange of ideas among the members, which will be of mutual benefit and ultimately be reflected in the betterment of the service if such a thing is possible.

It is only thirty-five years since the telephone was brought to public notice through the Centennial Exposition, yet in those years a wonderful development in the instrument and its application has taken place. When the telephone was born, it, like many other great inventions, was met with cold public favor, and it had a hard struggle to maintain its existence. But through the persistence and wisdom of its sponsors it won the battle and today the telephone industry stands as a monument to supreme engineering skill and business management, equalled nowhere in the world.

Most of the pioneers are yet young men, and if we can measure their future achievements by what they have done in the past thirty-five years, many wonderful things are awaiting their magic touch to be revealed to the world.

Interesting Facts in the Western Union Report.

It is highly encouraging to note in the annual report of president Theo. N. Vail of the Western Union Telegraph Company that there was an increase in the total revenue of the company of over three million dollars, or 9.57 per cent., notwithstanding the unsettled condition of general business. Under favorable conditions the revenue will, at this rate, make a splendid showing.

The increase of revenue, however, was more than offset by the increase in expenses, which amounted to $3,167,853, or 13.14 per cent. Over two-thirds of this additional expense represents increases in salaries, the actual amount applied to this purpose being $2,369,434 or 21.18 per cent. over last year. This is indeed substantial evidence that the company is standing by its faithful employes even at the cost of dividends to the stockholders. It seems to be the policy of the present managers to take care of the employes first and the latter are to be congratulated on their good fortune. As we have pointed out in previous issues the satisfied employe is the most valuable asset the company can possess, and the more valuable he is to the company the more valuable he is to himself.

The Evil of Oppression.

The average man likes authority, but all do not exercise it in the same manner. There is nothing so detestable as that form of authority known as oppression; and on the other hand it is a grand thing to use it in uplifting those who chance to be less fortunate.

It is indeed a sad sight to see one man in authority oppress those beneath him and treat them as though they were not worthy of any consideration, whereas the oppressor himself may have been one of the latter class before his advancement. Such a practice indicates a narrow mind, egotism and supreme selfishness. A man of this calibre is generally despised, except possibly by those who benefit by his favoritism.

Now take the man who exercises his authority for the good of his fellow men. He lays selfishness aside, encourages those beneath him to do better and generally is considerate of their welfare. He does not allow any personal animosities to bias his judgment of men. He remembers that he himself once was on a lower plane and looked up to those above him for inspiration, encouragement and guidance. Why, then, should he not practice these virtues when he advances to a position where he can exercise them.

We think it would be a good rule for telegraph and telephone companies when making appointments to positions of authority to give the appointee instructions as to his duties toward his subordinates as well as to his company and to himself. This could be done without any reflection upon a man's education in ethics, and certainly would be promotive of harmony and good feeling in the service.

The man who exercises his authority beneficently is universally loved and is the one most favored when honors are being distributed, but he who uses it otherwise is generally forgotten, if he does not pass into oblivion.

"Man's inhumanity to man makes countless thousands mourn" is the poet's way of expressing the same idea that impelled us to make these observations.

Digitized by Google

What the world needs today is more justice and humanity, and he who practices them in his life work is a benefactor of mankind.

The Telephone in Our Lives.

That the universal use of the telephone is effecting marked changes in our methods of living and transacting our affairs is well known, but in these days of rush and bustle few people think long enough to realize how extensive its ramifications are in our lives. As soon as a child is born the telephone enters its life; relatives and friends are telephoned to concerning the event and the wires are kept warm for a time. It has been calculated that a birth in small Western towns means on an average over three hundred additional telephone calls. If the child catches the measles or is otherwise ill the doctor is telephoned for and frequently prescriptions are given by wire.

The telephone comes into play again during the school period, and when manhood and womanhood are attained it is used for courting, proposing and even marrying.

In Washington the other day a couple decided to marry on short notice and the wedding invitations were issued by telephone — the ordinary means of communication being too slow.

The immense value of the telephone in business transactions need not be referred to in detail. Fortunes are made and lost and important deals are arranged and closed without even having to move out of our chair. We can stay at home and transact our business by telephone and there is no end of things that the telephone cannot do for us. Finally when we die the undertaker is telephoned for and condolences pour in over possibly the same wire that carried congratulations at the birth of the deceased. And so it goes; telephone, telephone, telephone, from first to last.

Cruelty to Messengers.

One of the most outrageous acts ever perpetrated by a grasping monopoly is the limitations placed upon pocket space in the new uniforms of the messengers of one of the telegraph companies. The company defends its action on the flimsy ground that bulging pockets in a messenger's uniform are untidy. But it is suspected that this is only a pretext for cutting down expenses, and the poor messenger is the victim of this latest form of greed. How are the boys to carry their revolvers, jack knives and dime novels if they have no pockets? This is "the unkindest cut of all" and is enough to rob the victim of every spark of ambition to become a detective.

Mr. E. E. Williams, district superintendent of the Western Union Telegraph Company of Atlanta, Ga., in renewing his subscription for another year, writes: "TELEGRAPH AND TELEPHONE AGE is increasing in value with every issue, and I do not see how anyone engaged in either branch of the service can afford to miss it. I am doing all I can to impress this idea throughout my district."

Increasing the Membership of the T. M. B. A.

To the Editor of TELEGRAPH AND TELEPHONE AGE:

SIR:—Since the Telegraphers' Mutual Benefit Association has opened its doors to admit telephone employes to membership, permit me to say a few words on the subject.

That the idea and purpose is an excellent one goes without saying, and it should receive the hearty and active support of every member. The association depends for its existence upon the constant accretion in membership, and, as it is a purely fraternal organization, the responsibility for its growth rests entirely upon the active interest taken in its affairs by the members.

Each member should give the association a little of his time at regular intervals. By pointing out its advantages to his associates now and then, and following up the prospects, will not take more than a few minutes' time, and will in the end bring in many new members. Immediate results cannot of course be looked for, but by taking the matter in hand in a systematic manner the effects will be surprising.

Telephone employes are numerous, and this field is a splendid one for action on the part of members. If each member brings in one new member a year the association's prosperity will continue.

Every effort should therefore be made by the members to get the telephone employes interested in the good work of the Association. It is a very worthy institution and has accomplished a great deal in the past. Its future success depends largely upon the co-operation of the members with the officials, and a few minutes' time now and then in this direction will bring forth fruit in abundance. Let us all join hands in the cause.

"A TELEPHONE MEMBER."

A. I. E. E. Los Angeles Section.—The Los Angeles, Cal., Section of the American Institute of Electrical Engineers opened the season of 1911-1912 with an informal dinner on October 17. The principal speaker of the evening was Dr. Jas A. B. Scherer, president of Throop Polytechnic Institute. Pasadena, Cal., whose subject was "Technical Education from the Practical Standpoint." Among the associates elected at this meeting was Mr. L. C. McIntosh, of Los Angeles, a well known member of the telegraph fraternity.

New York Electrical Society.—Major George O. Squier, of the United States Signal Corps, Washington, D. C., gave a lecture before the New York Electrical Society on October 27 on the subject of "Electric Waves Directed by Wires for Intercommunicating Purposes." The lecture dealt with the latest ideas and advances in the solution of the problems connected with this modern branch of electrical development.

Chinese Telegraph Restrictions.—The Chinese Government has placed severe restrictions on the telegraph lines, evidently for the purpose of preventing communication between the rebel leaders.

Course of Instruction in the Elements of Technical Telegraphy—II.

(*Copyrighted.*)

(Continued from page 678, October 16.)

We began in our issue for October 16 the publication of a course of instruction in technical telegraphy, which was prepared as a correspondence school course by Mr. J. H. Penman, of Rockport, Mass., an electrical engineer of ability and high standing.

The course is published for the benefit of those of our readers who desire to fit themselves for better positions in their vocation. It is elementary throughout and will be divided into chapters, following one another in logical order.

The course has received the hearty commendation of telegraph officials and experts for its scope and accuracy and its sound practicability. In each chapter examples will be given in order to illustrate the application of the rules to practical cases, and each chapter will be followed by a series of questions pertaining to the subject of the chapter, to be worked out by the student in order to review his progress.

The first lesson (October 16) covered a general description of fractions, and instruction and rules for the addition of fractions. In this issue we take up the same subject beginning with the subtraction of fractions. The mathematical section will carry the student through fractions, decimals, proportion, elementary algebra, etc.

SUBTRACTION OF FRACTIONS.

To subtract fractions:

RULE (6). *Reduce the fractions to fractions having a common denominator. Subtract the lesser numerator from the greater and place the remainder over the common denominator.*

Example: Subtract $\frac{1}{4}$ from $\frac{3}{4}$.

The least common denominator is 6.

$$\frac{3}{6}=\frac{4}{6};\quad \frac{4}{6}-\frac{1}{6}=\frac{3}{6}=\frac{1}{2}\quad \text{Ans.}$$

RULE (7). *When there are mixed numbers subtract the fractions and whole numbers separately and place the remainders side by side.*

Example: Subtract $9\frac{6}{32}$ from $17\frac{9}{32}$

The least common denominator of the fractions is 32;

$$\frac{9}{32}=\frac{18}{64};\ \frac{6}{32}-\frac{15}{64}=\frac{3}{32}.$$

Now take the whole numbers:

$$17-9=8.$$

Placing the remainders side by side: $8\frac{3}{32}$ Ans.

RULE (8). *When the fraction in the subtrahend is greater than the fraction in the minuend, borrow 1 from the whole number in the minuend and add it to the fraction in the minuend, from which subtract the fraction in the subtrahend.*

Example: Subtract $8\frac{7}{16}$ from $9\frac{1}{4}$.

The common denominator is 16.

Minuend	$9\frac{4}{16}$
Subtrahend	$8\frac{7}{16}$

We cannot take $\frac{7}{16}$ from $\frac{4}{16}$ so we borrow 1 from 9 and add it to the fraction, making $\frac{16}{16}+\frac{4}{16}=\frac{20}{16}$; $\frac{20}{16}-\frac{7}{16}=1\frac{3}{16}$. The whole number in the minuend being now the same as that in the subtrahend, the difference is $1\frac{3}{16}$. Ans.

RULE (9). *When the minuend is a whole number borrow 1; reduce it to a fraction whose denominator is the same as the denominator of the fraction in the subtrahend, and place it over that fraction for subtraction.*

Example: Subtract $8\frac{5}{16}$ from 9.

$9=8\frac{16}{16}$.

Minuend	$8\frac{16}{16}$
Subtrahend	$8\frac{5}{16}$
	$\frac{11}{16}$ Ans.

MULTIPLICATION OF FRACTIONS.

To multiply proper fractions:

RULE (10). *Multiply the numerators for the new numerator, and the denominators for the new denominator. All factors common to the numerators and denominators should first be cancelled.*

Example: Find the product of $\frac{3}{5}\times\frac{7}{10}$

Solution: There being no factors common to the numerators or denominators, we proceed to multiply:

$$\begin{matrix}3\times 7=21\\ 5\times 10=50\end{matrix}=\frac{21}{50}\ \text{Ans.}$$

Example 2: Find the product of $\frac{21}{32}\times\frac{5}{14}$.

Solution: Cancelling the common factor 7, we get

$$\frac{\overset{3}{21}}{32}\times\frac{5}{\underset{2}{14}}=\frac{3}{32}\times\frac{5}{2}$$

Multiplying the numerators and denominators:

$$\frac{15}{64}\ \text{Ans.}$$

To multiply improper fractions:

RULE (11). *Divide the product of the numerators by the product of the denominators.*

Example: Find the product of $\frac{11}{7}\times\frac{7}{8}$.

Multiplying, we get $\frac{77}{56}$

Dividing the numerator by the denominator:

$$1\tfrac{21}{56}\ \text{Ans.}$$

To multiply one mixed number by another:

RULE (12). *Reduce the mixed numbers to improper fractions and apply Rule 11.*

Example: Find the product of $2\frac{1}{8}\times 3\frac{1}{4}$.

Solution: Reducing to improper fractions: $\frac{17}{8}\times\frac{13}{4}$

There are no common factors so we multiply:

$$\begin{matrix}7\times 13=91\\ 3\times 4=12\end{matrix}=7\tfrac{7}{12}\qquad\text{Ans.}$$

To multiply a mixed number by a whole number:

RULE (13). *Consider the whole number as a fraction with 1 as its denominator, and apply Rules 11 and 12.*

Example: Find he product of $17\frac{1}{2}\frac{6}{7}\times 7$.

Applying Rules 11 and 12 and cancelling:

$$\frac{\overset{125}{\overset{8}{\overset{\cancel{16}}{\cancel{21}}}}}{\underset{1}{\cancel{8}}}\times\frac{\overset{1}{\cancel{7}}}{\underset{1}{\cancel{1}}}=125.\ \text{Ans.}$$

DIVISION OF FRACTIONS.

To divide fractions:

RULE (14). *Invert the divisor and proceed as in multiplication.*

Example: Divide $\frac{3}{8}$ by $\frac{3}{5}$.

Digitized by Google

Inverting the divisor: $\frac{3}{5} \div \frac{3}{2}$
Changing to multiplication:
$\frac{5}{5} \times \frac{2}{3} = \frac{9}{15}$. Ans.

Example: Divide $\frac{9}{16}$ by $\frac{5}{18}$.
Inverting the divisor: $\frac{9}{16} \div \frac{18}{5}$
Changing to multiplication and cancelling,

$$\frac{\overset{3}{9}}{\underset{1}{16}} \times \frac{\overset{1}{18}}{\underset{1}{5}} = \frac{3}{1} = 3. \quad \text{Ans.}$$

Example: Divide 5 by $\frac{9}{16}$.
Inverting the divisor, $5 \div \frac{16}{9}$
Changing to multiplication:

$$\frac{\overset{1}{5}}{\underset{1}{1}} \times \frac{\overset{8}{16}}{\underset{1}{9}} = \frac{8}{1} = 8 \quad \text{Ans.}$$

Example: Divide $7\frac{7}{16}$ by $3\frac{3}{4}$.
Reducing to improper fractions:
$7\frac{7}{16} = \frac{119}{16}$, $3\frac{3}{4} = \frac{15}{4}$.
Inverting the divisor: $\frac{119}{16} \div \frac{4}{15}$
Changing to multiplication and cancelling:

$$\frac{119}{\underset{4}{16}} \times \frac{\overset{1}{15}}{\underset{1}{4}} = \frac{119}{80} = 1\frac{39}{80}. \quad \text{Ans.}$$

DECIMALS.

A *Decimal Fraction* is a fraction whose denominator is some power of ten.

The powers of ten are 10, 100, 1,000, etc.

Decimal fractions may be expressed in three ways:

1. By words; as, three-tenths, twelve-hundredths.
2. By writing the denominator under the numerator, in the form of a common fraction; as, $\frac{3}{10}$, $\frac{12}{100}$.
3. By omitting the denominator and writing the fraction in a decimal form; as, .3, .12. The term decimal is usually applied to decimal fractions when expressed by the third method.

The *Decimal Point* is a period placed at the left of tenths, to designate the decimal orders.

A *Mixed Number* is a whole number, or integer, and a decimal written together as one number. The orders on the left of the decimal point are ***integral***, and those on the right are ***decimal***. The decimal orders are called *Decimal Places*.

The following table gives the names of a few integral and decimal orders, and shows the relation between them:

Integral Orders								Decimal point	Decimal Orders							
Hundred-millions	Ten-millions	Millions	Hundred-thousands	Ten-thousands	Thousands	Hundreds	Tens	Units	Tenths	Hundredths	Thousandths	Ten-thousandths	Hundred-thousandths	Millionths	Ten-millionths	Hundred-millionths

Any book on electrical subjects can be obtained at the office of Telegraph and Telephone Age, 253 Broadway, New York.

The Turin International Telegraph Tournament.

The international telegraph tournament organized in connection with the International Exposition of Labor and Manufactures, was held in Turin, Italy, August 22-26. There were 226 competitors, of which 114 represented the Italian administration and 112 foreign administrations, nine of them being women. The countries represented were Germany, Austria, Belgium, Brazil, Spain, France, Great Britain, Greece, Hungary, Roumania, Servia, Sweden, Switzerland, Turkey and the South African Union, no one being present from the United States.

On August 18 the International jury held a meeting which was presided over by Mr. Giuseppe Greborio, inspector general of Italian posts and telegraphs, president of the committee and judge. Mr. Greborio made an address in which he expressed the hope that cordiality and good feeling would be shown during the tournament. The rules governing the contest were then announced.

The competitors were received in the central office building on August 21 and the telegraph apparatus to be used for the contest was set into position.

On August 22 the contest began and was continued during the following five days. The records show that a speed of over 2,000 words per hour was attained on the Morse apparatus, and 1,500 words per hour on the Hughes instruments. The results on the Baudot system were "brilliant but not up to the average standard." In the Morse trials the two grand prizes were awarded to Italian contestants, and twelve gold medals went to Italian operators, three to Germans, two to Frenchmen, two to Belgians and one to a Swede.

In the Hughes contest the two grand prizes were awarded to operators from Belgium and Germany. Four gold medals went to Germany, two to Belgium, four to Austria, one to Hungary and one to France.

In the Baudot contest the two grand prizes went to France and gold medals were awarded as follows: Two to France, five to Italy and one to Austria. Silver and bronze medals were also given in each contest. The prizes were awarded on August 29.

The representative prize for groups of contestants from the same country was not awarded because there were no collective contests, neither was the championship prize awarded, for the same reason, all of the contestants entering individually. In the evening a banquet was held and congratulatory speeches were made and toasts drunk to the King of Italy and to the prosperity of foreign administrations.

New Hudson River Joint Cable.—A new cable is being laid across the Hudson river between Hudson and Athens, N. Y., for the use of the New York Telephone Company and the Western Union Telegraph Company.

Digitized by Google

Telegraph and Telephone Exhibit at Boston Exposition.

The accompanying illustration shows a view of the exhibit of the Western Union Telegraph Company at the Boston Chamber of Commerce Industrial and Educational Exposition at Mechanics' Hall, Boston, Mass.

The American Telephone and Telegraph Company, the Western Union Telegraph Company and the Western Electric Company occupied one side of the main entrance hall. The telegraph line shown in the picture extended from the telephone switchboard to the Western Union board, and a large electric sign, reading "Telephone and Telegraph," was hung beneath the aerial cable messenger wire. The scheme of arrangement of the telephone and telegraph was such as to naturally bring to the minds of visitors the benefits which they now enjoy from the close relations of the two companies.

EXHIBIT OF WESTERN UNION TELEGRAPH COMPANY AND AMERICAN TELEPHONE AND TELEGRAPH COMPANY AT BOSTON EXPOSITION.

In the Western Union space was located the switchboard and an Athearn duplex and single Morse set. On the next table a full Athearn quadruplex was mounted and adjoining this table was a telephone order table, thus illustrating very effectively to visitors the practically instantaneous connection between the telephone located at their homes and the Western Union Telegraph lines. Further along in the Western Union space was located an automatic printer and perforator. At the extreme left was located a ticker transmitting system with two other tickers connected thereto. Near the front rail were two more tickers printing respectively New York and Boston stock quotations during market hours. Next to these was a Burry page printer which was also operated during market hours. On a pedestal near the entrance was located a relay controlling a lamp which flashed in accordance with the sounder service furnished by the Western Union Telegraph Company, giving the exact Washington Observatory time. On the end

Digitized by Google

wall were five clocks, one being a master clock, and underneath these were a district call box and register.

All of this apparatus was set up for actual working and during the busy hours of the exposition, from 10 a. m. to 10 p. m., a force of operators, together with representatives from the commercial department, were on hand operating the apparatus and explaining the advantages of the service to the public.

A very lively interest in the exhibit was shown by the visitors at the exposition.

Railway Private Branch Exchanges.*

BY JOHN A. KICK.

In general office buildings, terminal yards, car shops and other points where a number of departments are represented a first-class telephone exchange service is necessary to the prompt handling of business in and between the several departments.

Originally one telephone was installed in the ticket or freight office and the agent expected to answer all calls, acting as a buffer between an impatient public and the railway company; whereas by the present method a private branch exchange, to which all departments have one or more lines, with skilled operators distributing the calls to the departments for which they are intended, avoids the annoyance of receiving calls intended for other departments.

The majority of the railways pay their exchange operators a good salary and as a result secure and retain excellent talent.

Railway officials must keep in touch with the changing conditions of the service, and to this end the private branch exchange acts as "information bureau" and is able, with very few failures, to locate any official upon a few moments' notice. The time-saved factor in railway work is of great importance and the private branch exchange has been a substantial contributor to that account.

When an official places a call through the private branch exchange he informs the operator whom he wishes to communicate with, hangs up his receiver and is called back when the connection is complete, thus saving to him the time intervening.

There has been a tendency toward overloading lines leading to these private branch exchange boards, causing heavy code signaling and slow service; but the situation is gradually clearing up, as it has been found that where service is justified good service is desired and can only be obtained by keeping down the number of instruments on the exchange lines, minimizing the annoying waits for an opportunity to use the circuit as well as doing away with the code ring.

Where two or more private branch exchange boards are installed at one terminal they are usually connected by trunk lines, with trunks from one or both to the nearest city exchange; but owing to the great desire to keep down wire mileage these trunks are not always of sufficient number to carry the service without serious delay.

The light on a private branch exchange board should preferably be a reflected, soft tone light, instead of a strong, direct light, which, reflected from the polished surface of the board, injures the eyes of the operator. The angle of the board with respect to the source of natural light, together with the wall and ceiling decorations, can just as well be arranged to produce a pleasing effect.

If possible terminal racks and cross connection frames should be so located as to be flooded with natural light for inspection and maintenance work, as well as prevention against rats and mice, which are liable to lurk in dark corners and destroy insulation.

All exchange boards should be separated from other departments and maintained as private offices, accessible to no one except in the discharge of duty, as good operating always needs the undivided attention of the operator.

Exchange operators are frequently required to do clerical work, handle telegrams (as phonegrams), and in other ways divide their time. On small exchanges where lines are short and the calls few this division of time of the operator may not be beyond good business policy, but where the exchange is a switching point for important through service or handles a heavy local business the accumulative loss of service, by reason of the operator not being free to give her whole attention to the operating, is considerable and if possible to capitalize would represent many times her salary per month.

The larger private branch exchange is under the direction and supervision of a chief operator and assistants who enforce the rules of discipline, correct methods of operating and stand responsible to the official under whose jurisdiction the exchange is operated.

*From *Telephone Engineer*.

Operating and Testing Manual.

"Electrician's Operating and Testing Manual" is the title of an excellent book by H. C. Hortsman and V. H. Tousley, giving practical instructions for the management, operation and testing of the more important electrical devices now in use. It deals principally with electrical machinery and apparatus, and contains much information of general value to the student of telegraph and telephone engineering. A careful reading and study of the book will give one a comprehensive knowledge of electrical application in all branches outside of telegraphy and telephony. It is free from higher mathematics and the facts given are easily understood, the language used in explaining them is so clearly stated. Every telegrapher should familiarize himself with the various applications of electricity and this work will help him acquire that knowledge. The book is bound in flexible leather covers, and is sold at $1.50 per copy. Address TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York, for copies of this or any other book on electrical subjects.

All telegraphers should subscribe for TELEGRAPH AND TELEPHONE AGE. It is up-to-date in all respects and highly interesting.

Digitized by Google

Telegraph Transmission.

In the discussion of the paper on "Telegraph Transmission" presented by Mr. Frank F. Fowle at the Chicago meeting of the American Institute of Electrical Engineers, June 28, Mr. Bancroft Gherardi said:

Mr. Fowle gives an interesting discussion of the problem of insulating telegraph lines. This is a very important question and one to which much study has recently been given in the telephone field, with the result that we are trying out a number of special designs of insulators, both of porcelain and glass. The paper suggests that a suspended insulator be adopted on certain telegraph lines. Much time and study will have to be given to this question before it is demonstrated that it will be necessary to make such a radical departure from existing insulator methods in order to obtain the desired results. A great many mechanical difficulties would have to be overcome in connection with the use of such insulators on telegraph lines, and it does not seem to me that it is as yet by any means demonstrated that we cannot, by the use of insulators of suitable material and suitable design, and supported on pins in the usual manner, obtain the desired results more cheaply and more satisfactorily than by the use of a suspended insulator. The suggestion in question is an interesting one, however, and I am very glad that it has been made, but it is my feeling at the present time that other and less radical methods are likely to accomplish the desired results.

The author's suggestion that much use might be made of copper steel wire for telegraph circuits raises at once a serious question in my mind. This wire has, I believe, in general, an ohmic resistance of about 2½ times that of hard drawn copper wire of the same diameter. It would, therefore, seem to me that the same reasons which have led the telegraph companies to so generally employ in their more important circuits hard drawn copper wire instead of iron would deter them from employing a material which would represent a step backwards in this most important characteristic of a line.

MR. FRANK F. FOWLE: The points brought out by Mr. Gherardi in relation to suspended insulators for telegraph lines I believe are well taken. The choice of a satisfactory insulator is necessarily a compromise between cost and efficiency, and on that score everyone seems to agree that the ordinary glass insulators now in service can be much improved upon. The question is how far we can go in the direction of better efficiency before the cost becomes too great—or in other words, where is the point of maximum commercial efficiency.

Before we can answer this question it is necessary to know what we can accomplish in improving the physical efficiency, without regard to cost. After settling that part of the problem, a cost study will fix the highest points of efficiency which is commercially feasible. My proposal for suspension insulators does not go farther than the first stage of the problem, and is along the line of obtaining the highest degree of insulation which is physically possible. An insulator of the suspension type is admittedly objectionable from a mechanical standpoint where the line wires are crowded together on the pole line, with the smallest feasible separation. On the opposite hand it seems to possess numerous advantages where the wires are few in number comparatively, and the climatic conditions to be met are severe. It is probably too soon to state any conclusions as to what forms and types of insulators will finally survive as commercially the fittest for various classes of telephone, telegraph and signal service.

Mr. Gherardi's remarks in relation to the use of copper steel wire—or, as it is more familiarly known, copper clad steel—indicate that he is thinking principally of conductivity, without full regard for other requirements. Tensile strength is a factor quite as important as conductivity.

The commercial field for any conductor of a new type, such as copper clad steel, is necessarily a question of economics. The latter phase of the subject has not been treated in the present paper, but it will be found in somewhat extended form in my paper on "Line Conductor Requirements for Telegraph Transmission," read before the Association of Railway Telegraph Superintendents, at the annual convention at Boston, June 26, this year. The latter paper contains a full substantiation of the statement made by me in the present paper, that copper clad steel finds its economical field in the lines less than 300 miles in length, approximately, where no repeaters are employed. If automatic repeaters are made use of, the economical range of copper clad steel wire is limited only by the feasible number of repeater sets from an operating standpoint. One set will extend the range to about 600 miles and two sets to 900 miles.

The substitution of copper wires for iron by the telegraph companies is probably traceable to several causes. The difficulty of maintaining iron wire in good condition has increased of late years, owing both to the use of inferior metals in manufacture and to the more general presence of corrosive agents in the atmospheres of cities, industrial regions and along steam railroads. The difficulties are increased by the fact that the life of the joints is not equal to the life of the body of the wire. Joints deteriorate rapidly and increase in ohmic resistance. The substitution of copper greatly diminishes the rate of depreciation, because the oxide coating on the surface of copper is protective and arrests further corrosion while it remains intact.

Owing to the fact that the tensile strength of hard-drawn copper does not exceed approximately 65,000 lbs. per sq. in., it is not feasible to employ small wires, except in mild climates. The telegraph companies have settled on a standard of No. 9 B. & S., weighing 209 lb. per mile, which has a breaking strength of about 620 lb.

The use of copper clad steel wire in place of this conductor is not economical except where the conductance of No. 9 copper is in excess of the transmission requirements. For example, the use of No. 9 copper for a telegraph line 150 miles long is an economic waste of copper, because a much small-

Digitized by Google

er conductor would provide the necessary conductance. At the same time the correct size of copper from a conductance standpoint would not be strong enough to sustain loads of wind and sleet, and would not give reliable service—if in fact it would stay up at all.

Such a case forms an ideal illustration of the value of copper clad steel wire, whose tensile strength is approximately 90,000 to 100,000 lb. per square inch. This type of wire could be substituted for solid copper, in this instance, with considerable saving in cost, because its superior tensile strength permits the use of smaller sizes than are permissible with copper.

Of course the substitution of copper clad steel for copper, where the size of copper needed electrically is also sufficiently strong mechanically, is out of the question. Had my statement that copper clad steel is an economical and suitable telegraph conductor been unaccompanied by the important qualification that 300 miles is the limit on its use in circuits without repeaters, Mr. Gherardi's general objection on the score of low conductivity would be well sustained. But in the light of all the analysis of the problem it seems to be clearly established that the superior strength of copper clad steel wire, taken in conjunction with present market prices, proves it economical for distances in simplex service up to about 300 miles.

Telegraph Rates in Great Britain and the United States.

In his annual report Mr. Theo. N. Vail, president of the Western Union Telegraph Company, has this to say in regard to telegraph rates in Great Britain which are generally used in arguments for government ownership of telegraph lines in the United States:

The telegraph rate of Great Britain is often used to argue the possibility for similar telegraph charges in this country or as an argument for government ownership and operation of the telegraph.

While the English rate is small, so are the distances and area covered by the rate small. According to the official figures of the British telegraph system, the deficit for the last year obtainable was over $5,000,000. This deficit includes interest only on a capital of about $50,000,000, whereas, as a matter of fact, there has been a total expenditure up to date, for capital expended and unextinguished, for loss of interest and for working expenditure over receipts, approximately, of $175,000,000. In the expenses charged against the revenue there are no allowances for depreciation or depreciation reserve. About $1,250,000 for extensions, not nearly enough to offset proper depreciation, is charged against revenue. No taxes are paid. This item is a large one in a private enterprise. No rental or charge for buildings owned by the Postmaster-General. There is no liability for or payment of damages from any cause whatever.

The wages paid to telegraph employes of Great Britain are only 50% to 70% of wages paid by the Western Union for same classes of service.

The average operating cost per message, official figures, which do not include any of the above mentioned material and unavoidable items of the expense of a private enterprise—is over 20 cents. If all the items were added to expense that would have to be borne by a private enterprise, the cost would be increased by a very considerable amount, certainly 25%, and probably nearer 50%, or increased to 25 or 30 cents. The average revenue per message is about 15 cents; in other words, one-half of the cost of every private telegram is directly and indirectly borne by the public revenue.

The telegraph system of Great Britain is and has been maintained for the convenience of its users at the expense of the general revenue. The British rate is 12 cents for 12 words and 1 cent for each additional word, address and signature counted and charged for. The Western Union 25-cent rate for 10 words (address and signature, an average of 9 to 10 words, free) covers about the same area in territory and the same average distance of telegram that the British rate covers. The territory of Great Britain is about the same as that of five middle States, but 75% of the population are within 200 miles of London.

Compared with the British telegraph wire system, the Western Union telegraph wire system covers an area twelve times as large. The Western Union wire mileage is five times as great. The Western Union has nearly twice as many offices. The distance between the most distant principal commercial centers is ten to twelve times as great as in the British system.

Comparisons of greater distances and larger rates cannot be made except on a Continental basis. The rates from London to European points vary from 4 cents a word, address and signature counted and paid for, covering distances from 225 miles, up to 12 cents a word, address and signature counted, for about 2,000 miles; while the Western Union maximum rate is $1.00 for 10 words, address and signature free, for 3,500 miles.

Heavy Telegraph Business at Base Ball Game.

During the first game of the world's baseball championship series at New York on October 14, 160,000 words of telegraph matter were transmitted from the Polo Grounds in less than two hours, over 48 loops. The longest circuit operated direct from the grounds was to the Denver *Times*, Denver, Col., a distance of 2,000 miles. The longest circuit of the Commercial News Department was to Kansas City. The greater part of the 160,000 words was not written at all, but was dictated direct from the reporter to the operator.

TELEGRAPH AND TELEPHONE AGE is the leading paper in these two fields and is progressive and newsy. Subscription price, $2.00 per year.

THE TELEPHONE PIONEERS AND A HISTORY OF THEIR WORK.

INTRODUCTORY.

IT IS fitting that the telephone pioneers should meet in Boston to organize an association, for it was in Boston that the telephone was conceived and born, and Boston was for many years the center of its development.

The great expansion of telephony is a marvel in industrial history, and what makes it the more wonderful is the fact that the age of the industry is just half that of the life-time allotted to man. It is only 35 years of age, and history can nowhere exhibit a record of such rapid growth. Most of the men who contributed in any way whatever toward the upbuilding of this great organization are still alive, and, in fact, are yet young. They, to the number of over 200, have made a pilgrimage to Boston at this time to form an association to be called the "Telephone Pioneers of America," with a view to holding meetings annually and thus getting together on a social plane.

The term "pioneer" is usually associated in the popular mind with the idea of age, but that notion will have to be revised in this instance because the men in the association are not old in years, although they are certainly old in experience.

The two great figures in the history of the telephone are its inventor, Dr. Alexander Graham Bell, and Mr. Theodore N. Vail, who has been the master mind in the development of the business organization almost from the beginning. Dr. Bell furnished the cornerstone and Mr. Vail was the architect of the great superstructure which today is represented by the American Telephone and Telegraph Company and its associated companies.

DR. BELL AND HIS INVENTION.

It will be interesting in this connection to refer to the circumstances that led to the invention of the telephone and the difficulties and skepticism that the inventor encountered on every hand. But Dr. Bell seems to have had an insight into the future which his contemporaries knew nothing of, for had he not been so sanguine as to the ultimate value and success of the instrument he would have yielded to the discouragements which beset him on all sides.

Alexander Graham Bell was born in Scotland, and was educated in Edinburgh, the city of his birth, and in London, and in one way or another picked up a smattering of anatomy, music, electricity and telegraphy. At the age of 16 he left home to become a teacher of elocution in various British schools, and by the time he became of age had made several discoveries as to the nature of vowel sounds. Shortly afterward he met in London two distinguished men, Alexander J. Ellis and Sir Charles Wheatstone, who did more than they ever knew to forward Bell in the direction of the telephone.

When he was 23 years of age he moved to Brantford, Canada, with his parents. This was in 1870. In 1872 he went to Boston, Mass., where he lectured on vocal physiology at the Boston University, besides giving lessons to private pupils.

Now the telephone was not the only matter in addition to his regular duties that the inventor had on hand at this time. He was also engaged with inventions in harmonic multiple, and autographic telegraphy, and being too poor to prosecute his researches independently, had entered into an arrangement with certain gentlemen (one of whom, Mr. Gardiner G. Hubbard, subsequently became his father-in-law), under which they should pay the expenses of experimenting with these telegraphic inventions and of obtaining United States patents for them, while he should give up a portion of his professional work and give the time thus saved to telegraphic experimentation. These gentlemen, who thought something could be made out of the telegraphic inventions, but had no faith in the speaking telephone, and regarded it as being wholly chimerical and fantastical, naturally wished to push the multiple telegraph invention forward, and discouraged work on the latter. Dr. Bell was sure of his ground, however and he worked persistently until 1875 when the instruments he then turned out were really good, practical telephones.

APPLICATION FOR PATENT.

The application for the patent was filed in the Patent Office on February 14, 1876, and the patent when granted on March 7 of the same year bore the number of 174,465. After an eventful life of seventeen years, during which time it bore with invariable success the brunt of a litigation unexampled in the annals of patent law, it expired on March 7, 1893.

It was at this stage of its development that the telephone was exhibited at the Centennial Exposition held at Philadelphia, Pa., in the summer of 1876. Its exhibition there was the beginning of its public career. There, its capabilities and the remarkable results of its operation attracted the admiring attention of many distinguished votaries of science; and it was the recipient of much appreciative acclaim and laudatory remark from Professor Joseph Henry and Sir William Thomson (later Lord Kelvin) of the board of judges of the scientific section.

Stimulated by his Centennial success, the inventor of the telephone devoted himself during the latter half of 1876 to its improvement and made many structural advances, which for the most part he sought to describe and protect in a second patent granted to him on January 30, 1877.

COMMERCIAL DEVELOPMENT.

We now come to the commercial period of the telephone and all through its development we see the towering and commanding figure of Theodore N. Vail.

It was to Mr. Vail that the struggling infant industry turned for help in its early days and his has been the guiding hand through the greater part of its wonderful career.

The telephone had ceased to be a "scientific toy" and became an article of commerce. It began to be taken seriously, although the London *"Times"*

Digitized by Google

had referred to it as the "latest American humbug." Mr. Gardiner G. Hubbard, was the first to become interested in the business end of the telephone, and Mr. Thomas Sanders supplied the little capital to start it. In a short time Mr. Hubbard was leasing telephones at the rate of a thousand a month. He was no longer a promoter but a general manager and it became necessary to find some one to organize the business.

"Watson," said Mr. Hubbard to Prof. Bell's assistant "there is a young man in Washington who can handle the situation. Run down and see what you think of him." Mr. Watson reported favorably upon his investigation and in a couple of days the young man received an offer from Mr. Hubbard to become general manager at a salary of $3,500 a year. "We rely," Mr. Hubbard said, "upon your executive ability, your fidelity and your unremitting zeal." The young man replied: "My faith in the success of the enterprise is such that I am willing to trust to it, and I have confidence that we shall establish the harmony and co-operation that is essential to the success of an enterprise of this kind." One week later the same young man, Theodore N. Vail, took his seat as general manager in New York and the building of the business began.

Line by line, Mr. Vail, mapped out a method, a policy, a system. He introduced a larger view of the telephone business and cast aside all proposals to sell out. Then the first Bell Telephone Company was organized with a capital of $450,000 and a service of 12,000 telephones. Having stiffened up the backbone of the little company Mr. Vail proceeded to establish a definite business policy. He revised the contracts and made them good for five years only; he confined each agent to one place and reserved all rights to connect one city with another. He established a department to collect and protect any new inventions that concerned the telephone, and took steps toward standardizing all telephonic apparatus by controlling the factories that made it. All of these measures were part of Mr. Vail's plan to create a national telephone system.

It was soon recognized that the future of the telephone was highly promising, and many bright young men, largely from the allied industry—the telegraph—cast their lot with it, and thus came to the aid of Mr. Vail in carrying on his great work. There was no precedent to follow; it was a new enterprise and all knowledge concerning the business was derived at first hand through experimentation. The development soon reached a point where it was seen that more scientific methods were imperative in the engineering and operating departments, and then the colleges furnished trained minds to place the business on a scientific basis. Mr. Vail's methods were so far-seeing and his judgment of men was so keen and accurate that he soon gathered around him a staff of assistants whose ability and loyalty have challenged the admiration of the world.

Most of the men who have figured in the wonderful development of this industry are expected to be present at the organization of the association of telephone pioneers in Boston, and no doubt many entertaining stories will be told of their early experiences. The American Telephone and Telegraph Company today stands as a monument to their work and skill, and at the end of this article their names are given.

HISTORY OF THE TELEPHONE.

A brief review of the history of the telephone from the time the first line was established will prove of interest at this time.

The first telephone line was erected in Boston in the spring of 1877 between the factory of Mr. Charles Williams, Jr., the manufacturer of the telephone, and his residence at Somerville. This line was finished and put in operation on April 4, 1877. Numbers of people came to see and try it, and orders began to come in for telephones and telephone lines.

Before the end of April other telephone lines were constructed, connecting Professor Bell's laboratory

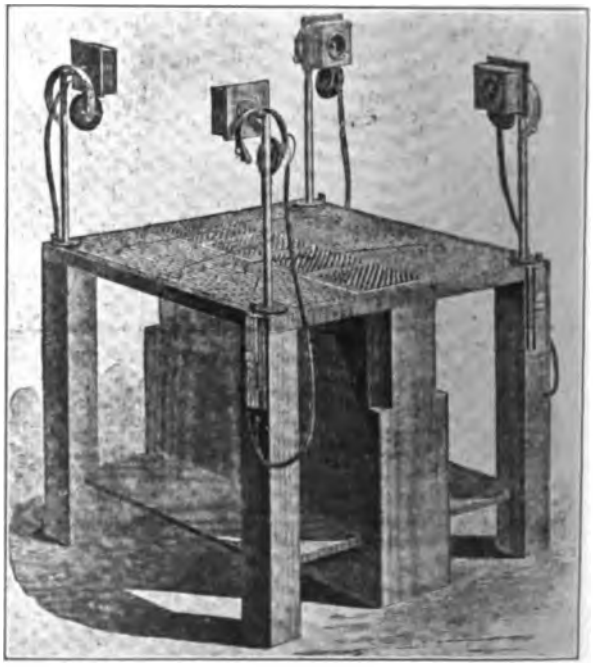

FIG. 1.—FOUR-HUNDRED LINE LAW SWITCHBOARD, 1878.

in Boston with the factory of Mr. Williams, and other points in the city, and in the early part of May an agreement was made with the Board of Waterworks of the neighboring city, Cambridge, Mass., for the equipment with telephones of a line connecting the principal office of the department in the city with the works at Fresh Pond, a couple of miles distant.

The idea of using the telephone as a time-saving appliance, and as a means of communicating intelligence, began to spread; and telephone lines put up for business purposes in the city of New York and in Altoona, Pa., closely followed the Cambridge installation.

During the months of April and May, 1877, applications for agencies began to come in with increasing frequency, and the business management was constantly engaged in disposing of exclusive privileges and territorial licenses under the patents, and in meeting the rapidly enlarging demands for telephones.

Digitized by Google

THE FIRST EXCHANGE.

Boston was the scene of the earliest instance of the interconnection on the exchange plan of lines having out-stations equipped with telephones for direct communication between the stations of any two lines, and this occurred in May, 1877. At this time the business of providing electrical protection against burglary was carried on by the Holmes Burglar Alarm Company, and to this company a number of telephones had been furnished for trial and experiment. From the central station in Boston burglar alarm circuit lines radiated to a number of banks and stores, each line being provided with apparatus at the central point by means of which the burglarious entering of its station might be announced; and arrangements were made for the use

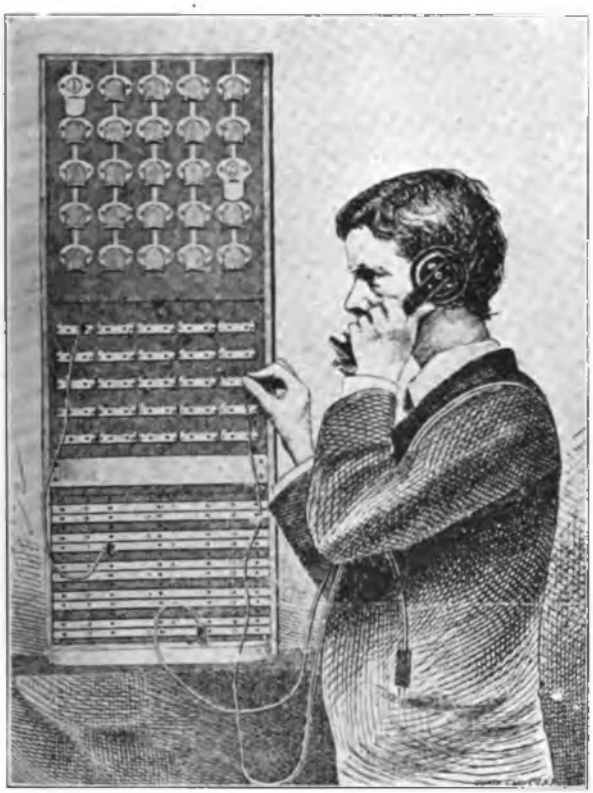

FIG. 2.—SECTION OF SWITCHBOARD, PHILADELPHIA EXCHANGE, 1879.

of these lines, their sub-stations, and the central station as an experimental telephone exchange. These lines were repeatedly interconnected, and many conversations were interchanged between their stations, the burglar alarm apparatus being employed to transmit the regular call signals. This was in fact the first telephone exchange.

From this time forward the work of furnishing telephones and of sending them out for commercial purposes advanced by leaps and bounds. By the late summer of 1877 it had become clear that some sort of an organization was necessary to take charge and properly supervise the commercial development of the telephone, which was assuming dimensions of very considerable magnitude. As a temporary expedient, the owners of Mr. Bell's telephone patents, who at this time were very few, including merely Mr. Bell, Mr. Gardiner G. Hubbard, certain members of their respective families, Mr. Thomas Sanders and Mr. Thomas A. Watson, Mr. Bell's assistant, formed themselves in August of that year into a sort of informal unincorporated association having no capital; to which was given the name of the Bell Telephone Association. It was formed to assist and act in support of Mr. Hubbard in the management of the business relations of the telephone, and in devising the best means for its general commercial introduction.

By this time the work of the Bell Telephone Association and its management had become so heavy that the expediency of a more formal and more effective organization of ownership was manifest. The Association realizing this necessity, took its first action in this respect by forming the New England Telephone Company, which was incorporated under the general laws of Massachusetts on February 12, 1878, with a capital of two hundred thousand dollars, and by granting it the exclusive right to use, license others to use and to manufacture telephones in the New England States.

Attention was next turned to ways and means for extending the use of the telephone throughout the United States outside of New England; and to this end the Association proceeded to create the Bell Telephone Company, which was incorporated with a capital of four hundred and fifty thousand dollars, July 30, 1878, also under the general laws of Massachusetts.

The telephone central office system at New Haven, Conn., was opened for business on January 28, 1878, and was the first fully equipped commercial telephone exchange ever established for public or general service, and by March, 1881, within a year after the American Bell Telephone Company began business, there were in the United States only nine cities of more than ten thousand inhabitants, and only one of more than fifteen thousand, without a telephone exchange.

In March, 1879, the Bell and New England Telephone Companies were coalesced and the new organization, with a capital of $850,000, was called the National Bell Telephone Company. At the close of the year this Company stood alone as the proprietor of telephony within the United States. The scope and plan on which the National Bell Telephone Company had been organized were seen to be incommensurate to the expansion already in sight. Accordingly, on March 19, 1880, the American Bell Telephone Company was incorporated by a special act of the Massachusetts legislature with an authorized capital of $10,000,000, and, purchasing the property, took over the business of the National Bell Telephone Company. In conformity with the growth of the business, the American Bell Telephone Company increased its capital from time to time, so that at the end of 1899 the outstanding stock amounted to about $26,000,000. The property and business of the company were then transferred to the American Telephone and Telegraph Company, a separate corporation which it had organized in 1885 to develop the long line business,

Digitized by Google

and the American Bell Telephone Company discontinued its general business.

When in the spring of 1880 the American Bell Telephone Company assumed charge of the business there was no underground construction, and the

FIG. 3.—SWITCHBOARD USED IN NEW YORK IN 1880.

lines, for the most part of iron or steel, were altogether on roofs or poles.

The telephone circuits were single wire lines with earth returns; cable making was an imperfectly mastered art, and cables crude and untrustworthy; the use of copper line wire was little known and discountenanced; there were no standards in construction and apparatus, every man doing and adopting what might be right in his own eyes.

Since that time metallic circuit low capacity polyconductor cables, mainly employing air as an insulating medium, have been devised, and their employment has become universal; underground construction has become the rule instead of the exception; beginning with the year 1886 a metallic circuit system of long distance lines has been built of hard drawn copper wire, and has overspread the country; the average excellence of these long lines, terminating as they do in switchboards at exchange central stations, has resulted in correspondingly improved construction in exchanges everywhere, including the substitution of copper for iron as a material for line wire, and the metallic circuit for the ground return single-conductor line; the operating companies now have their own buildings specially designed to accommodate the central station operating rooms, and affording facilities for the ingress of the subterranean cables; an elaborate system of protection has been provided for both ends of each telephone line, and where such lines pass through cables, at the cable ends also, to take care of trespassing currents strong enough to be destructive; and lastly, but by no means of least importance, the old and well-known hand-operated magneto machine—for years the most approved call-sending apparatus—and the multitudinous batteries of which one was provided with the transmitter of each user to furnish current for its operation, have both been superseded in the modern well appointed exchange, by a single central station battery which supplies

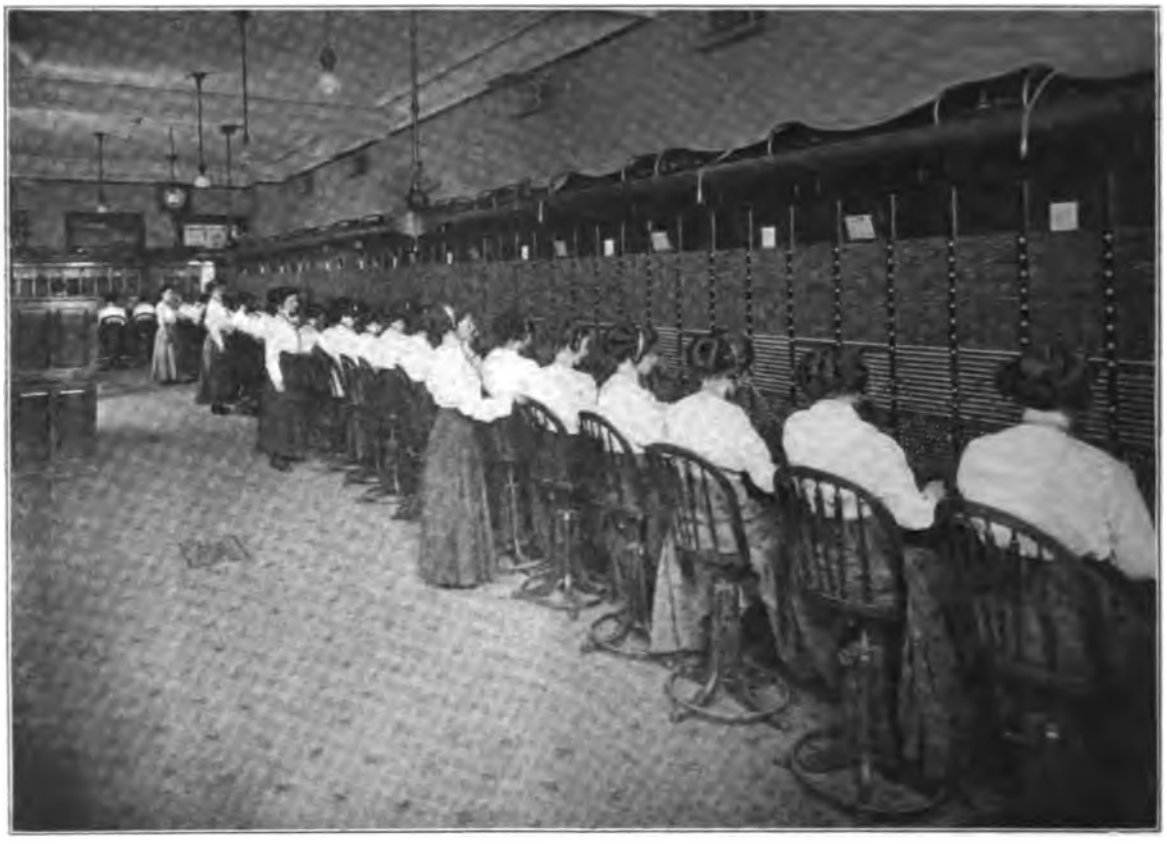

FIG. 4.—MODERN TELEPHONE EXCHANGE IN NEW YORK.

Digitized by Google

not only the electric current for all the transmitters of the outlying stations, but also for the transmitters of the central station, and for the switchboard lamps used for call and supervisory signals.

These advances which have systematized the technical side of telephony, and which have received the approval of, and have been made available by the foremost telephone engineers in all parts of the earth, are largely attributable to the ability and persevering application of the headquarters' engineering staff; and to the stimulating and encouraging attitude towards practical and meritorious improvement in appliances and methods which has uniformly characterized the management.

The original plan upon which the telephone business was started provided for the issuance of a license by the American Bell Telephone Company, the owners of the patents, to use the Bell patents within certain defined territories, the instruments being furnished by the Bell Company. Rights were given to use the invention in perhaps a single county, or even a single city; but as time went on it was found that this did not yield the best results, so the consolidation of local telephone interests into large companies covering many counties, and even in several instances the whole or the greater part of the entire States was undertaken.

With the movement towards consolidation it was seen at once that large sums of money must be raised for the extension of the business; and in order to aid the operating companies, and at the same time to keep such an interest in them as would enable the owners of the patents to assist in giving the public telephone service, the policy of the company owning the patents was to invest in the stock of the companies operating under licenses, and funds, secured by issue of the stock of the American Bell Telephone Company, were sown broadcast in construction over the whole United States.

The result of this policy of investment in local companies has been that the American Telephone and Telegraph Company has at present a financial interest in the telephone business in every part of the United States. It has persistently and steadily worked towards the end that there shall be a system of telephone and telephonic communication so homogeneous in its construction and its methods that, regardless of the part of the country where it may be used, or however distant the point with which communication may be desired, every part of the machinery of administration and operation shall work together harmoniously to give the best possible results to the public.

LONG DISTANCE SERVICE.

The American Telephone and Telegraph Company is only in a minor degree an operating company. It has a department which builds and operates the so-called Long Distance lines, whose object is to tie together the districts of the various local companies, and to handle the business which passes from the territory of one of the operating companies into that of another.

Starting in 1884 with the experimental line between Boston and New York, the long distance service has grown with enormous rapidity, until today it reaches over all of the eastern section of the country, meeting the Canadian system at various points on the boundary line, and extending beyond the Mississippi to Denver, Col., embracing therefore all of the United States east of the Rocky Mountains.

With this growth there has sprung up a multitude of new uses for the telephone. We find in office buildings and hotels the private branch exchange; telephones of special design, adapted for special uses, may be found in mines and on railroad and street railway systems, and in some of the larger and newer houses the older systems of electric bells and speaking tubes have been displaced by a private telephone equipment communicating with every part of the house.

Trains have been equipped throughout their entire length with telephones, so that travelers may converse without the trouble of passing from one car to another, and when the train draws up to a railroad station, by means of a flexible conductor the train system is connected to the local system, so that passengers may talk to their friends in the town, and may even carry on long distance conversations. Steamships are provided with interior telephone systems, and these can also be connected to that of the city when the steamer is lying at the dock.

One of the most interesting fields of recent development of the telephone has been in the application of the telephone to the railway service. Telephone messages and telegraph messages may be sent simultaneously over the same wire, and at small stations and out-of-way points it is no longer necessary to have a telegraph operator, as by the introduction of the telephone on such lines the station agent may be in constant communication with the train dispatcher and officials at headquarters.

More important from a social standpoint than any of these mentioned has been the rapid extension of the telephone among the farmers and into the rural districts. In many places farmers have built their own lines into the exchange limits, and placing from ten to twenty instruments on a line, have thus put themselves into close communication with their market towns and the larger centres of population. The farmers on any individual line are able to converse with one another without calling up the central station, and by means of the central office, often located in a farmer's house and attended by his wife or daughter, these isolated farm houses can be brought into connection with all the surrounding country.

PRESENT DAY TELEPHONE STATISTICS.

In his report for the year 1910 President Vail of the American Telephone and Telegraph Company says:

"The interest of the American Telephone and Telegraph Company in its associated operating companies is over 80 per cent, in addition to which it has its own earnings. The American Telephone and Telegraph Company's share of the surplus earnings of the Bell system is approximately 90 per cent, so that the showing of real interest to the security holders of American Telephone and Telegraph Com-

Digitized by Google

pany lies in the figures of the Bell system as a whole.

"The number of exchange stations connected with the Bell system December 31, 1910, was 5,882,719, an increase of 740,027 for the year. The increase for the year was nearly as great as the total number of exchange stations ten years previous. Of this number 1,852,051 were stations of independent companies, called connecting companies, operating as a part of the Bell system under sub-license or connecting contracts.

"The total wire mileage, not including that of connecting companies, in use for exchange and toll service was nearly 12,000,000 miles, an increase of nearly 1,200,000 miles for the year. Fully one-half of the exchange wire mileage is underground. There were 167,800 miles of toll and long distance pole lines, with nearly 2,000,000 miles of toll and long distance wires. The public indulged in over seven thousand million conversations during the year at an average cost of a little over two cents a conversation.

"Plant additions during the year cost $53,500,000. The total addition to plant in the past 11 years amounted to $460,750,000. The total property additions during the year were $84,000,000.

"The gross revenue collected from the public in 1910 for telephone service by the Bell System—not including the connected independent companies—was $165,600,000; an increase of nearly $16,000,000 over last year. Of this operation consumed $54,000,000; taxes, $8,000,000; current maintenance, $25,700,000; and provision for depreciation, $26,200,000. The surplus available for charges, etc., was $51,000,000, of which $11,550,000 was paid in interest, and $25,000,000 was paid in dividends to the public.

"The average earnings per exchange station for exchange service were $31.28, as against $44.68 for the year 1900. The average net earnings, including toll earnings, per exchange station, were $10.15, as against $15.60 in 1900. The average construction cost per exchange station was $117.00; including the toll lines, $142.00, as against $199.00 in 1900."

This then is the new art, the new and greatest service of intercommunication the world has yet seen, which has been developed and spread the world over by the men assembled in Boston today—the Telephone Pioneers of America and their associates.

Russian Telephone Service.—The telephone service in Russia is maintained partly by the Government and partly by private companies. The zemstvos are also exploiting the telephone service in sixty-nine counties. The Government maintained ninety-nine urban telephone lines and four long-distance lines. Besides this a telephone service was carried on between thirty cities by means of telegraph lines for the purpose of transmitting telegrams. The receipts from the Government's telephone system amounted to $1,370,855 and the expenditures to $774,393, yielding a profit of $596,462. A telephone service was also maintained in fifty-five cities by private companies.

Pioneers of the Telephone.

Following is a list of the telephone pioneers, classified by the years in which they entered the service:

1875.

Bell, Alexander Graham, June
Harrington, Frank W.
Watson, Thomas A., June

1876.

Barton, Enos M.
Kinsman, F. E.
Maynard, Geo. C.
McCluer, C. E.
*Sargent, Wm. Dunlap

1877.

Baker, Hugh C., Oct. 18
Brown, Robert
Candee, Willard L., Aug. 31
Childs, W. A., May
Denver, W. J.
Devonshire, Robert W., Aug.
Doolittle, Thos. B., June
Dunstan, Kenneth J., Oct.
Ehrlich, Herman
Field, Stephen D.
Ghegan, John J.
Glidden, Charles J., May 8
Holmes, E. T., May
Jackson, W. A., Oct. 1
Joyce, Martin J., Nov.
Korty, L. H., Nov.
Lillie, N. W., Oct. 8
Mason, F. C., Oct.
Murphy, J. O., June
O'Brien, Richard
Pope, Henry W.
Rolfe, Charles A., March
Scribner, C. E.
Wainman, C. P.
Wiley, Geo. L.
Wilson, Charles H.
Wood, F. G.

1878.

Adee, Daniel M., June
Adkins, W. H.
Adler, C. H., April 1
*Allen, Fred'k A., May 1
Bailey, Thos. B., Feb. 28
Baker, Ellis B., Jan. 31
Bawsel, E. E., Feb. 6
Berliner, Emile, Sept.
Betts, George E., June 1
Blake, Francis
Boeggeman, J. H., May
Butler, John K.
Cornish, Thomas E.
Crenshaw, A. P., Sept. 22
Culbertson, J. N., April
Delano, Frederick M.
Delany, Geo. W., Oct. 1
Doolittle, Chas. B., July
Evans, Wm. R., Sept. 25
Hall, Edward J., Nov.
Kelleher, Chas. F., Oct.
Ladd, J. W.
Lockwood, Thos. D.
McComas, R. T., Sept. 1
Martin, J. J., April
Martin, T. Commerford
Mehaffey, J. H., Sept.
McCoy, John A.
Richards, W. L.
Schultz, H. J., Dec. 26
Thompson, A. K.
Vail, Theo. N.
Vaille, Frederick O., Nov.
Wadland, Thos. H., Nov.
*Watson, Henry M., Nov.
Westbrook, W. T., April
Woelk, Edward A., June
Woolverton, W. H.

1879.

Baxter, M. S., April
Boutillette, H.
Boyce, C. L., Oct. 8
Brown, Joseph M., May 1
Brownell, C. H.
Burleigh, Chas. B., Aug.
Buttrick, F. A., Aug.
Byrne, C. J., Aug. 1
Carney, M. J.
Carrigan, G. H., June 30
Carty, J. J.
Chapman, Wilson S., Nov. 1
Conn, F. W., Aug.
Daboll, Frank G., Mar. 21
*Eastabrook, W. N., Sept.
Fitch, D. H.
Fitzpatrick, Thomas P.
Gallagher, A. C., April
Gardner, C. E., Oct.
Gentry, W. T.
Hanchett, W. D.
Helsher, Louis H., Dec. 3
Hyde, Henry D.
Kearns, John, Sept.
Keenan, W. J.
Keller, Jasper N.
Kilbourne, H. W., Nov. 1
Lillie, Edward E., April
McDaniel, Chas. W., May
McFarlane, Lewis B., July
McLellan, Alexander
Mackenzie, Cecil W., April 1
Manson, Geo. T., Dec. 7
Milne, G. D., April
Moran, Jno. M., Aug. 6
Nicholson, Chas. A., Nov.
Paynter, W. D., Jan. 1
Pittman, Edward Y., June
Root, Charles M., Jan.
Sherwood, E. F., June 10
Smith, A. T., Dec.
Stanford, Joseph D., Nov.
Stearns, J. W., March
Storke, H. L., June
Sunny, Bernard E., Mar. 1
Thomas, M. F., Feb.
Truex, Charles R., Sept.
Warner, Frank E., Dec. 1
Willard, Edmund S., May
Wilson, Eugene M., May 17

*Deceased.

Early Days of the Telephone in Pittsburgh.

In a letter Mr. Thomas B. A. David, an old time telephone man of Pittsburgh, Pa., tells of the organization of the Central District and Printing Telegraph Company, and his early experiences in its development.

"The company was organized by me in 1874," he says, "for the purpose of putting all the larger concerns in Pittsburgh in communication with each other by means of printing instruments and a central office. I began the business with one boy, John Connors, now an operator in the Pittsburgh office. Early in June, 1877, Mr. Gardiner G. Hubbard, who was in full control of the Bell Telephone, came to Pittsburgh to see me. When he explained the object of his visit I said, 'Oh, it is only a toy and I am too busy to give the matter any attention.' He replied, 'Don't say that: come to my room.' There he produced some magneto telephones. I was not slow to see a merit in the invention. Its possible, useful feature absorbed my whole attention, and I conducted many experiments under all sorts of conditions.

"The first experiments in Pittsburgh were made between my house and a building on the rear of the lot, and soon after I had a wire strung from my office in the First National Bank Building to the Iron Exchange on Fourth Avenue for public exhibition. I also had a wire from one end to the other of the Exposition Building in Allegheny, for the same purpose. It has recently been told that Professor Alexander Graham Bell sought out a man to do this experimenting at the exposition, to whom he offered a large interest. Professor Bell had nothing to do with the introduction of the telephone in Pittsburgh, and Mr. Hubbard had control of the business end of Bell's invention.

"On one occasion, in July, 1877, I made a long distance (!) test between Somerset and Mt. Pleasant (some 20 odd miles) by metallic circuit. Mr. David Fleming and Mr. Samuel L. Gilson went to Mt. Pleasant, and a Mr. Miers and myself to Somerset. As we were using the wires of the Western Union Telegraph Company, the experimenting had to be done in the early hours of the morning. Magneto telephones have but little power, and not much was accomplished. We did talk, but not satisfactorily. The immediate result, however, was that Fleming and Gilson were in danger of being arrested as escaped lunatics, for it could not be understood why two sane men, in separate rooms, would be howling, Hello! at four o'clock in the morning."

The Telephone During the Austin Flood.

In an article on the Austin, Pa., flood resulting from the breaking of the dam on September 30, some interesting details are given in *The Telephone News* regarding the part played by the telephone operators in warning the people of the danger.

Miss Kathleen V. Lyons notified the subscribers by setting the alarm automatically and then remained at the board and notified subscribers in Austin and Costello, a small town three miles down the valley.

Miss Lyons was the only operator on duty. She said that her first report of the breaking of the dam came from a man in a nearby house by calling over the telephone located there. The first thing she did was to call the large mill immediately below the dam. Several hundred employes were at work there and most of them owe their lives to the fact that Miss Lyons stayed on duty when the danger to herself was great. Then she began to call officials of the town, the fire department and others. She notified the proper ones to blow the whistle constantly—a generally understood warning to flee to the hills.

Miss Lyons states that it was about eight minutes between the time she received her first warning until she left the switchboard, and then she left it only when she saw a church steeple, a block away from the office, topple and fall into the street. She then left the switchboard and fled for her life up the side of the mountain. The water was actually at her heels.

Miss Margaret Manion, the chief operator at Coudersport, proved herself a heroine at the same time. When she heard of the trouble she called the trouble man and told him what had happened. He in turn told the operator to order him an automobile as he left the building. She did so, and notified every doctor and official that she could reach. In a few minutes every machine in Coudersport was headed at top speed towards Austin in an effort to render assistance.

At Galeton, about twenty miles northeast, when Mr. C. R. Shelly, plant wire chief, heard of the flood he obtained two telephone sets, rushed to the scene in an automobile and connected them to toll lines. Mr. C. E. Lovell, the local agent, later received orders from the company's officials and permitted survivors and others to call up their friends at out-of-town points to state that they were safe.

The telephone company, in recognition of the heroism displayed by the Austin operators, rewarded them by presenting Miss Lyons with $250 and a watch suitably engraved; Miss Lena Binkey, chief operator, $100, and Hazel Knapp $50.

Some Recent Developments in Railway Telephony.

Some interesting and valuable facts were brought out in the discussion which followed the reading of the paper of Mr. Gregory Brown on "Some Recent Developments in Railway Telephony," at the Los Angeles, Cal., meeting of the American Institute of Electrical Engineers.

MR. KEMPSTER B. MILLER said:

The matter of railway train dispatching, discussed by Mr. Brown in his paper, is one of great importance, not only to telephone men, but to railway people and the public at large. There is an impressive mileage of railroads, important railroads, that are now being operated by telephone rather than by the telegraph, and this fact is surprising to those who have not watched and been in close touch with the development of this branch of telephony.

An interesting thing in the discussion of the power transmission papers, day before yesterday, was that some companies had seen fit to build a separate pole line for the telephone circuit, distinct from the power transmission line. That is not because it is impossible to put telephone wires on transmission poles and get fairly good service, but in order to effect an extra precaution to insure telephone transmission at the time it is most needed. In many cases that is not done—I should say in the great majority of cases. Now, if the power transmission companies are, for added security, willing to build a separate pole line for telephone circuits when they already have a high grade line, the question naturally arises in my mind in regard to this telephone railway train dispatching, is it wise for the railroads to load up the talking circuit with the selective ringing apparatus? I see no reason for even suggesting the building of another pole line in the case of railway circuits; but it does seem to me that in many cases the building of a separate copper circuit, or iron if the conditions warrant iron, for operating the selective bells would be warranted. This separate circuit for the operation of the selective bells on the dispatching system, would prevent loading down, with ringing apparatus, a circuit already overloaded with a multiplicity of bridged talking circuits. I understand that some railroads are doing it, but that many others have refused to spend the necessary amount of money. In view of the extreme importance, particularly from the standpoint of the safety of the public, I think this phase of the subject worth discussion.

MR. L. B. CRAMER: I have noticed, in regard to the ringing of the bell at the station called, the sending keys are made of such a size, that if they were made a little larger they would not make a cabinet of extremely large dimensions, and the amount of space that can be given to them would then be enough to produce a ring long enough to call the operator. I notice our dispatcher often calls a second and even a third time. In case of substations, where the bell is mounted on a booth, there being some noise in the machines, we have an auxiliary bell that makes plenty of noise and the substations are the stations from which we get the best responses.

In regard to the switches, which have one position for receiving and one for transmitting, I have already thought of making some changes in the apparatus because in stations where we have a set that is mounted on a desk, about the second or third day after the telephone is in operation, the agents get a ruler or a stick and plug the button. This, perhaps, could be made a subject of discipline and, taken care of in that way, and you could get the result which you are supposed to get by being able to hear better by leaving the button in normal position and only press the button in when you are talking. The agent and operator will do these things and when there is a train coming, or anyone whom they think will see it, they will take the plug out; but ordinarily they will leave it plugged up so when they want to O. S. a train, they will not have to work the plug.

MR. RALPH W. POPE: Mr. Chairman, there does not seem to be anyone here to take up the telegraph operators' view of the situation.

Now it has been my experience in my fifty years of knowledge of the Morse telegraph, that the people who do not understand it and work it don't appreciate what a beautiful and simple method it is of transmitting communications. It may be of a little bit of interest—to add a personal touch—if I tell you that years ago, having some fifty pages of what would now be fifty pages of typewriting, to copy, and several manifold copies to be made, that Mr. Edison, my brother, one other operator and myself took turns in sending and then copying down from the sounder. We did that because it is an easier way to copy it from the sounder than by looking from one page to another. You simply write and the words go in your ear and go out of your pen or pencil onto the paper and that becomes so automatic that in the course of receiving a long press report, as we did during the Civil War, the operator was obliged to take a bunch of carbon paper and change the sheets at the bottom of each page so as to pick up the work when a new batch of sheets were ready, and this involved keeping behind about fifteen words, behind the sounder, and it took all of the next page to catch up with the sender. I am giving you this as an instance of what the telegraph system really is. Now, we take the way station of a railroad and the operator always has to look out for baggage and various things around the place and wherever he is in that room, no matter whether he is called or not, he knows what is going on over the wire. Of course, if he is called, he is obliged to answer. As an instance of what an operator can pick up in that way, I went down from Great Barrington, to Sheffield, expecting to ride back on the passenger train. It was bulletined on the telegraph board "No Report." I thought I could get to Great Barrington for dinner, but I could not find out whether I could and I sat there waiting to get my lunch, growing hungrier all the time. Meanwhile I heard a message going over the line that the train had been delayed, and that they would meet at Canaan somewhere below, and so on: and I fig-

Digitized by Google

ured out it would be an hour and forty minutes before the train would be along. So I went to the operator and said, "How late is your train going to be?" He said, "I don't know; I have had no report of it." I said to him, "According to the information I received, they are going to meet at Canaan, and it will be about an hour and forty minutes wait, and I thought I would have time to go out and get my lunch." "Well," he said, "you are a pretty good guesser."

Perhaps what we may call that particular qualification of the telegraph would not appeal to the railroad management, that a man outside could find out how the trains were running. The point I am endeavoring to make in this is, that the Morse system is available to that man wherever he may be walking around the place. He has not got to go and answer a call and put a telephone up to his ear and drop everything else; but he takes that incidentally with his other work. That is simply one of the features of the Morse system that appeals to the railroad telegraph man. You must remember also that a great many of the men who are in active management are practical Morse operators, have grown up with the system, and know what it can do. This question has been discussed before several conventions of the Railway Telegraph Superintendents. So you will see that there is another side to the question. Here you have a railroad force developed from telegraph operators who are familiar with a system of this kind, and it is the simplest and best thing that appeals to us in carrying on this work. Were a sounder there, I can receive a message sitting here, and I don't have to hold anything to my ear at all. I simply sit down and write from it, and where a man has grown up with it and is familiar with it, he never can get over that love and appreciation of the simplicity of the Morse telegraph system as known to the one who has practiced it, although it is now thirty years since I have done so.

MR. K. B. MILLER: I can add my little personal touch there, although a much less skilful operator than Mr. Pope was, and having no right to claim to be an old timer, that it is much easier for me, or would have been in days gone by, to have written down matter taken from a sounder than to get it by telephone. Mr. Pope's remarks suggest a distinct need in railway train dispatching. Some way may be evolved of relieving the dispatcher, who is a rather important man, from wearing a harness—I refer to the head telephone. They don't like to do it. The loud speaking receiver has been proposed and tried out rather carefully, and so far as I know has failed. One very ingenious way has been proposed and tried, but has not met with good results owing to poor articulation. It is to use at the dispatcher's station a telephone repeater so that the feeble incoming currents could be magnified to produce loud talk in the receiver, and thus relieve the dispatcher of the necessity of listening to a receiver held to his ear. This produced plenty of noise, but it is articulate speech rather than noise that railway train dispatching needs.

MR. RALPH W. POPE: I might add to my remarks that the conditions which I spoke of in regard to the railroad service have changed very much within my recollection. When I entered the service, the station agents knew nothing about the telegraph, so in order to have telegraph facilities, the railroad was obliged to have an operator in addition to the agent, so that today we have this different state of affairs where the telegraph operator has grown up to be the agent, and the agent therefore is not necessarily obliged to have an operator at his station, on his staff. This means nothing in large stations where they have several employes, because there is enough work to keep the operator busy; but in small stations it simply means that one man, by his knowledge of telegraphy, his knowledge of railroad work, can be the whole thing.

MR. GREGORY BROWN: Mr. Miller brought up the question of separate signaling circuits. There is one type of selector, so far as I know, that uses three wires—one for signaling and two for talking. That has not been very extensively used. When you consider the impedance of the selectors across the line, it hardly seems necessary to consider that line very heavily loaded as far as transmission is concerned. For that reason, I do not believe it would be necessary to have a separate signaling wire. Selectors are also being experimented with now that have an impedance of something over 600,000 ohms. These selectors contain advantages due to that high resistance, and if they are used, it certainly would not be necessary from a transmission standpoint to have an extra signaling wire.

Mr. Cramer seems to have had quite a few troubles. The first he mentions is that he does not find it feasible to signal and talk at the same time. I have been around pretty nearly all over the country on the various roads, and this is a complaint that is practically new to me. In some cases I have found this to occur, but on investigation we generally find that there is some trouble with the dispatcher's apparatus. One of the troubles that occurs perhaps more than any other and causes these results is the breaking down of the condensers at the dispatcher's office. These would not round off a sending wave to such a great extent.

The length of ring has been criticized—the length of ring at the station. I have gotten around that, where they want a longer ring, by installing a strap key at the dispatcher's office. This key is wired in parallel with the automatic keys, and if the dispatcher, for any reason, wants the bell in the station he is calling to ring longer than would ordinarily be the case, he turns the calling key of that station, and when he hears the answer back he merely presses down the strap key. There are various other modifications of selector arrangements which permit the bell to ring in the substation until the substation operator presses a button. In fact, most any kind of service can be given, according to what the particular railroad wants, but, as a general thing, most of them are satisfied with a certain length ring, about a second and a half, uniformly in all stations.

Another trouble that was experienced was that the agent sticks a toothpick or something in the push button and holds it down. The obvious plan to pur-

Digitized by Google

sue there is to dismiss the agent; and this has been done in a great many cases, especially when the telephone was first used on railroads. As has been mentioned by several of the speakers, the operators objected a good deal at the introduction of the telephone, their idea being that they probably were going to have their salaries reduced ,or some of them would lose their jobs. It is not the policy of large railroads to put men out of employment except in very extreme cases, and if the introduction of the telephone permits offices to be closed, or forces to be reduced at certain points, the men as a rule are taken care of in some other position.

Mr. Bennett spoke of calling and selecting on transmission lines. Mr. McMeen answered this question about the only way it can be answered, I guess, and that is with proper transpositions of your line if you get a quiet telephone line you can do anything with it in the way of talking and selecting.

Mr. Pope brought up the point in favor of the telegraph in that you could hear the telegraph when you were at some distance away from the instrument, whereas in the telephone you have to have the instrument up to your ear. About two months ago I conducted a trial installation down on one of the Pennsylvania lines, using a new type of loud-speaking receiver. Criticism has been made of the telephone when used on a railroad division that it was all right for every purpose except blocking, and that for this purpose it was not as quick as the telegraph, and this criticism seemed to be more or less justified. The reason that this criticism was made was that in telephone blocking it is necessary for the operator to ring up another operator and then go through the motions of putting the receiver on his head and talking with him, whereas with the telegraph he merely ticks off what he wants to say and it is done. And that was the reason for the development or the experiments with loud speakers of various kinds and the attempt to develop a good one.

There has been considerable work done on this, and, although it has been comparatively easy to get up a loud speaker for blocking—one that was plenty loud enough—still the articulation was not what it should be. This blocking service represents an ideal condition for loud speakers, because the lines are extremely short and are not loaded, and you can take full advantage of all the energy coming out of the transmitter. This installation was put in in three or four of the towers, and was left in for about ten days. During that time it was used exclusively by the operators for blocking trains, and in fact they much preferred to use these speakers because the work was easier for them. They were then taken out merely to put them in in a better shape the next time as far as mounting is concerned, making it more convenient for use, and also to employ a busy test by means of a buzzer that had not been taken care of in the first installation. It is intended to use or experiment with this same type of receiver for dispatcher's use, and there will shortly be some trials in that field.

Mr. Elwell spoke of a train dispatching line being in use in Australia in 1902, I think it was. In the first part of my paper I mention two or three instances of the early installation of telephones on a train wire. All these installations used code ringing, and for that reason they were not very successful. There was too much of a load on the dispatcher. I think the first one used in this country was in 1883, which is probably before the one mentioned by Mr. Elwell.

I think there is no doubt that the telephone has proven its case on the railroad, and I mention in the paper quite a few advantages of the telephone over the telegraph and I can probably mention quite a few more, and anybody who thinks of the matter can easily see that there is no question but what the telephone does have advantages over the telegraph. Mr. Miller, I believe, raised the point about the distinctness with which the intelligence could be transmitted over the telephone—that is, where train orders, important orders regarding train service in which human life is risked—the distinctness with which they could be heard. Now, in sending out orders, the various railroads have standardized, in their telegraph methods, and they have also adopted practically the same scheme when they shifted over to the telephone. In sending out an order the despatcher rings the various operators and they will come in and then he states a certain number, 31 or 23, or whatever it is, which indicates the type of order he is to give and he starts to give his order, and as he gives his order he writes it down himself so as not to give the order faster than the operator can take it down. As the dispatcher writes the order when he comes to the name of a town or any figures whatever, engine numbers or anything similar, or the time, besides speaking it in the ordinary manner, he spells it out. After he has completed giving the order the operators in their turn repeat this back to him and as each operator repeats it back to him the dispatcher underlines the word repeated, so if there are three operators repeating the record of the order would be in the dispatcher's book—it would have three underlines under each word which was repeated, which would supposedly prove it had been repeated by three operators.

A telegraph manager in a western city, who recently purchased a copy of "Telegraphers of To-day," expresses his delight with it. He writes: "It is a splendid record of the telegraphers of almost 20 years ago, and the excellent portraits of those who figured in the telegraph at that time make a book of great value and a work of reference in these later days."

Copies of this book may be obtained of TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York, at $1.00 per copy, express charges collect.

Every one connected with the telegraph and telephone services should read Telegraph and Telephone Age. Its columns contain the latest news in these fields.

International Telegraph Monument.

We have received from the Bureau of the International Telegraph Union, Berne, Switzerland, a photograph of the model of the monument which will be erected at Berne to commemorate the founding of the International Telegraph Union. The photograph is reproduced herewith.

The monument was designed by M. Romagnoli of Bologna, Italy. It is of bronze and stands on a stone foundation.

In conception it represents all parts of the world connected by telegraph, and in the design this sentiment is portrayed as a whole rather than by depicting the individual races.

The central figure shows the spirit of telegraphy and the Union is expressed by the joining of hands with the figures at both sides.

On the two tablets are engraved the names of the twenty original states which founded the Union, and at the back of the monument there is a blank tablet for a more ample description should it be desired at any further time.

MONUMENT TO COMMEMORATE THE FOUNDING OF THE INTERNATIONAL TELEGRAPH UNION.

Wires and insulators are shown to add character to the design and as an evidence of the conception.

The monument is very symmetrical, and the two blocks of stone on either side of the approach are designed to harmonize with the surroundings at the point where the monument is to be erected.

The overall dimensions of the monument are 59 feet in diameter and 19½ feet high.

The first international telegraph convention was concluded between certain central European states on June 29, 1855.

At the Paris conference in 1865 these gatherings were placed on a more systematic footing, and at the Rome convention in 1871-72 the submarine cable companies were first represented.

At the conference in Libson, Portugal, in 1908, it was proposed that the jubilee of the conference be commemorated by the erection of a monument at Berne, Switzerland, which proposal was agreed to by the respective governments.

The next convention will be held in Paris in 1915.

Short Period Telephone Service.

Appreciating the needs of the business man for regular and efficient telephone service between the home office and branches, the American Telephone & Telegraph Company devised a plan for furnishing regular daily periods of service at reduced rates, with all the features of the private wire contract for all day service.

That the plan has been exceptionally interesting to the larger users of long distance service is evidenced by the fact that numbers of them have adopted the "Short Period Service," as it is called, and find that in addition to decreasing the cost, it systematizes the telephone end of their business.

The periods offered subscribers are from 30 minutes daily up to the full business day of 10 hours, and a recent new departure occasioned by the demand, is the dividing of a 30-minute period into two 15-minute periods, thus enabling a subscriber to contract for 15 minutes' service both in the morning and afternoon.

The Short Period contract must be made for some period before 10.00 o'clock in the morning, after 4.00 o'clock in the afternoon or during the noon hour.

The price varies for different periods and different distances, but is attractive because it is a monthly regular service, and has a stated time price for traffic that can be handled more economically than can emergency messages.

The contract provides for an absolutely private wire and all of the operating is done by the subscriber. There is no placing of the call with the operator, no waiting for the connection to be made and no three-minute rate. The wire is there at the stated period, placed at the disposal of the subscriber for instantaneous communication with his branch office.—*Telephone News.*

Receiver for a Telegraph Company.—It is announced that the Consolidated Printing Telegraph Company, with headquarters at Newark, N. J., has gone into the hands of a receiver.

The New Buffalo Office of the Postal Telegraph and Cable Company.

BY J. P. O'DONOHUE, DIVISION ELECTRICAL ENGINEER, POSTAL TELEGRAPH-CABLE COMPANY, NEW YORK.

On Sunday, August 27, the Postal Telegraph-Cable Company took possession of its new quarters at Buffalo, N. Y.

The new office is stated to be the finest telegraph office in the country in point of equipment and attractiveness, and many new ideas and improvements are noted. Among them may be mentioned the electric lighting; the call circuit cabinet: the messengers' uniform room; bath rooms for the boys; the switchboard equipment; the use of flameproof wire; separate fusing of potential leads; use of Edison street current for main and local circuits, etc. It occupies portions of the first, second and sixth floors and basement in the Prudential Building at the corner of Church and Pearl Streets.

FIG. 1.—GENERAL VIEW OF THE BUFFALO OPERATING ROOM.

There are two large illuminated signs fitted into recesses in the building and reading: "Postal Telegraph-Cable Company." The letters are made of translucent blue and white glass, and the frames are covered with ornamental hammered copper. Tungsten lamps are used to illuminate the signs, which present a beautiful appearance by daylight and are even more attractive at night.

Supplementing the signs are two trade-marks and two "messages," each four feet wide, painted alternately on four of the large plate glass windows. The fifth window is lettered with a "cable" panel.

The receiving, cashier's and delivery departments and manager's office are located on the ground floor and are elaborately furnished throughout. The counter is of Tennessee marble and is surmounted by a cast bronze grill of beautiful design. The office furniture and trim are of mahogany and harmonize with the deep olive walls and cream colored ceiling. In the inner offices the mosaic floor is covered with rugs. The lighting is supplied by seven five-hundred-watt tungsten lamps suspended twelve feet from the floor.

The call-circuit cabinet, equipped with twenty-eight circuits, and two telephone exchanges, carrying nine trunk lines and eighteen extensions, are also upon this floor.

In the basement are located the terminal room, supply room, line department and the messengers' uniform room; also two one-horse-power motor blowers which are used to operate the pneumatic tubes connecting the different departments.

The terminal room is built of fireproof material and is equipped with four hundred porcelain terminal blocks mounted on an angle iron frame. The messengers' uniform room is quite unique, being made entirely of iron grill work. This construction in addition to being non-inflammable is highly sanitary as well as insuring proper ventilation. Adjacent to the uniform room is a shower bath for the boys and lavatories for the ground floor employes.

On the second floor are the operating and bookkeeping departments, a retiring room for the women and locker and smoking rooms for the men.

The operating department occupies the southern wing and is finished in oak with buff walls. The switchboard equipment consists of an angle iron switch frame with sheet iron panels divided into three sections holding two fifty-wire main line boards carrying eighty wires and a legboard with a capacity of two hundred spring jacks. Under each main board are located two rows of fifty and one row of twenty-five pin jacks, while under the legboard there are four rows of fifty-pin jacks. These jacks carry all the local circuits from around the room, the transfer loops between sections, and the branch office loops. All of this equipment is mount-

Digitized by Google

ed on slate. The iron frame work and panels are stained and grained oak to match the furniture.

In the rear of the switchboard are the terminal frames. These frames, as well as the switchboard frame, are as near fireproof as it is possible to make them. The frames of angle iron are equipped with three hundred porcelain base combination fuse blocks and arresters, twenty-two hundred cross-connecting terminals mounted on slate bars, and

FIG. 2.—REPEATER RACKS AND MOTOR GENERATORS.

eight hundred Ward Leonard resistance coils. Flameproof wire is used throughout upon the frames. All main line wires are protected with half ampere two-thousand-volt fuses and arresters, with ten-mile separators.

One of the most interesting features of the office is the new type repeater table, which was described and illustrated in the September 16 issue of TELEGRAPH AND TELEPHONE AGE. There are two banks of sixteen sections each and one bank of twenty sections, equipped with thirteen quadruplexes twenty-two duplexes, six main line repeaters and three half repeaters.

FIG. 3.—VIEW OF PUBLIC RECEIVING ROOM.

The fourteen quartette and one sextette operating tables provide sixty-two sittings which are wired for eighteen flip-downs, twenty-seven main line sets, ten annunciators for short wires, two quadruplexes and a phantoplex set. Postal standard extension arm resonators are used on all tables. The asbestos-lined wiring cabinets at the end of each bank of tables are placed directly over cement hand holes, fitted with sectional castings which are removable when it is desired to obtain access to the hand holes.

All potential leads and cables under the floor are run in inch-and-a-half black iron pipe. The cable used consists of twenty-six pairs of No. 19 B. & S. twisted silk and cotton insulation, lead covered. The potential leads are of No. 6 B. & S. rubber insulation, lead covered, and No. 12 B. & S. twin, rubber insulation, lead covered.

The room is divided into four sections, the potential leads for each section being fused separately so as to avoid complete interruption to any of the leads in event of an accidental short-circuit.

The generator plant consists of eight motor-generators with 110-volt primaries. Three five-horse-power Crocker-Wheeler 385-volt machines furnish current for the quadruplexes and three three-horse-power Crocker-Wheeler 200-volt machine for use in Wheatstone measurements and a 150-volt alternating current machine for phantoplex work.

Directly above the machines are the switches, rheostats and voltmeters upon slate panels. Back of the panels bus-bar construction is employed and all starting boxes are equipped with no-voltage release attachments.

The primary power is supplied through special leads from the Buffalo General Electric Company's mains by a three-wire direct current system, 110 volts on each side, with the neutral grounded. The motor load is divided equally between the two sides. Special leads from the building plant are provided for emergency use in case of interruption to the regular supply of current. The current employed at the main board is taken directly from the 110-volt mains through resistance coils, as is likewise all current for local circuits. Two-thousand-ohm coils and 150-ohm instruments are used on all such circuits.

FIG. 4.—VIEW OF OFFICE EXTERIOR.

Digitized by Google

Another new idea which has been worked out in this office is the local signaling system which permits an operator to call in the repeater chief on his circuit without delay in case of an interruption. This is accomplished by means of cam switches located at the operating tables controlling lamp annunciators at the multiplex sets.

The room is illuminated by thirty 100-watt lamps with holophane shades, giving a uniform distribution of light without shadows.

The chief operator's desk is located upon a raised platform and commands a view of all sections of the room.

In the northern wing of the building are located the bookkeeping department, women's rest room and the locker and smoking rooms for the men.

The superintendent's offices are on the sixth floor and are fitted up and arranged with modern equipment.

The staff of the Buffalo office consists of Messrs. Harvey D. Reynolds, district superintendent; C. H. Newman, manager; J. W. Sullivan, chief operator; E. S. Washburn, day wire chief; J. F. Harrington, day repeater chief; Nathaniel Hucker and W. O. Weydman, day traffic chiefs; J. B. Slocum, night chief; George A. Cross and George W. Thrall, night traffic chiefs; Wm. A. Moran, all-night chief.

Telephone and Telegraph Practice in England.

Mr. Angus S. Hibbard, of the American Telephone and Telegraph Company, New York, is the author of an article in the *Postoffice Electrical Engineers' Journal*, London, entitled: "Some Observations on Telephone and Telegraph Practice in England."

Mr. Hibbard visited England last Spring to look into the workings of the telephone and the telegraph, where the two systems were operated together to transmit or receive telegrams, and he found in the routine and manner of working much that was interesting and instructive. Telephones, he states, are successfully used instead of telegraph instruments in handling telegrams at branch offices, the telephone being generally preferred by the staff employed at nearly every office he inspected.

"The telegraph concentrators were most interesting," says Mr. Hibbard, "and their application, as I saw them, excellently worked out. The greatest delay in handling telegrams is no doubt caused by the prevailing use of code addresses, making reference to books of code words necessary before telegrams can be delivered. This delay under the present systm seems unavoidable, but it must cost fully as much as the sum received annually for the registration, and involves the greatest delay experienced in any part of the telegraph system. I am sure I should prefer the American plan of free addresses, especially when telephone addresses are used, making immediate delivery by telephone possible. The number of telegrams between two points in London, while decreasing on account of the more frequent use of the telephone, still seems very great. Telegrams costing a shilling or more, which could be telephoned direct for twopence, are still in evidence. The adoption of a telephone address, recommended by the Committee investigating telephone deliveries, will do much to speed up a considerable porportion of the London service."

The Anglo-Belgian Loaded Telephone Cable.

One week after the Anglo-Belgian loaded telephone cable was laid a fault occurred, which was localized at a point about 2½ miles from St. Margaret's. Repairs were effected in about 12 hours, and the fault was found to be due to a bad joint between one of the cores and the insulation of the coils. The short time required to remove this fault, which naturally included the inserting of a new set of coils, shows that there is no difficulty in repairing this class of cable.

The cable differs from the one laid between Abbott's Cliff and Cape Grisnez, which is still in perfect condition in so far as special loaded coils have been introduced, which enable a superimposed or "phantom" circuit to be worked, in addition to the two ordinary loop circuits.

Following are some interesting details of the "constants" of the **new cable:**

Resistance per nautical mile of loop conductor without coils.	14.2 ohms at 15° C.
Capacity per nautical mile of loop conductor without coils.	0.157 mfd.
Capacity per nautical mile of phantom circuit without coils.	0.314 mfd.
S/K at 800 cycles per sec. and 15° C., and is not proportional to frequency.	12
Self-inductance of the coils for the transformer circuit.	0.1 henry.
Ohmic resistance of the inductive and non-inductive coils in the transformer circuit.	6.6 ohms.
Effective resistance of the inductive and non-inductive coils of the transformer circuit at 800 cycles with 1 milliampere at 15° C.	11.5 ohms.
Self-inductance of the coils in the phantom circuit.	0.05 henry.
Ohmic resistance of all coils in the phantom circuit.	3.3 ohms.
Effective resistance of all the coils in the phantom circuit at 800 cycles with 1 milliampere at 15° C.	4.6 ohms.
Capacity of the coils in the transformer circuit.	.004 mfd.
Additional capacity of the coils in the phantom circuit, less than	.0001 mfd.

The cable was manufactured and laid by Siemens Brothers & Co., London, England.

Glass Telegraph Poles.—Glass telegraph poles are manufactured in Germany. The glass mass whereof these poles are made is strengthened by the interlacing and interwining with strong wire threads. It is asserted that the glass poles show their superiority over wooden ones by reason of their resistance to the ravages of insects in tropical countries and against the climatic influence or rain, snow and sleet in other countries.

It is the general opinion that TELEGRAPH AND TELEPHONE AGE stands at the head of periodicals of its class. Every telegrapher and telephonist should be a subscriber.

Insulating Materials.*

Insulating materials may be classified into distinct groups as follows, according to the nature of the material:

(1) Stony materials, such as slate, marble, mica, asbestos and porcelain.

Slate is an excellent insulating substance for use as terminal boards, provided it be free from metallic veins. It is non-combustible, easily broken, but tougher than porcelain, and is liable to absorb moisture unless varnished. It is improved by being boiled in paraffin. Its insulation resistance per mil. thickness for one square inch cross-section is 0.5 megohm.

Marble is an excellent insulating substance, and is tougher than slate, as it is not so liable to be affected by moisture, although it is readily affected by some acids. It is non-combustible, but it begins to conduct like an electrolyte at temperatures near to a red-heat.

Porcelain is a good insulating substance for bases, supports for terminals, and for insulating bushes. It is, however, brittle, and if subjected to much strain, easily broken, consequently care is required in fixing porcelain insulators. It is non-combustible, but, like marble, it begins to conduct as an electrolyte at temperatures near to a red-heat.

Mica is an anhydrous silicate of aluminum and potassium or soda, found as deposits in India, Canada and the United States, the best quality for electrical purposes being obtained from India. Its specific resistance is very high, being 30,000 megohms per square-inch-mil. It withstands high temperatures readily, and is particularly well adapted for use in electrical machines, as it powerfully resists penetration or puncture by a spark, the best qualities being able to withstand 5,000 or more volts with a thickness of one mil. It, however, lacks flexibility and uniformity, and tends to permit surface leakage. It is extremely useful as a component of artificial insulating compounds, such as micanite, mica-canvas, mica-long-cloth, megohmite.

Micanite is formed by cementing together thin laminæ of mica by special gums (i.e., pure shellac), and insulating cements under high pressures and at a high temperature. At normal temperatures its specific resistance is 1,000,000 megohms per square-inch-mil, but when the temperature exceeds a certain value (above 150 deg. C.), the cement suffers chemical decomposition, and if the voltage to which it is subjected for a given thickness is gradually increased, a point is reached at which it loses its insulating quality and is traversed by a current which heats it up and burns it, rendering it defective as an insulator. It may be bent into suitable forms when heated.

Mica-canvas is formed by cementing scrap sheets of mica about 2 mils thick between two sheets of canvas, so that the strips of mica overlap one another, and when the total thickness is about fifty mils, and has been baked in a steam-heated oven for twenty-four hours, it will withstand a pressure of 3,000 volts (alternating). Its specific resistance per square-inch-mil is 300,000 megohms.

Mica-long-cloth is made in a similar manner by cementing scrap mica between very thin linen fabric to a thickness of twenty-five mils., and its specific resistance is 300,000 megohms per square-inch-mil.

Megohmite is also a mica composition, whose specific resistance is high, and which can readily be molded.

Asbestos has a specific resistance of seven megohms per square-inch-mil. and withstands high temperatures readily. It is weak mechanically and readily absorbs moisture.

Vulcabestos is another insulating compound which consists of asbestos cemented together with a small quantity of rubber and vulcanized, and as it retains its insulating qualities at temperatures as high as 300° C., and may readily be molded it is a very useful product. Its specific resistance is fifteen megohms per square-inch-mil.

Ambroin is formed by mixing fossil copal and silicates by a special process, which enables a strong, firm, uniform, durable, and non-hygroscopic material to be produced. As an insulator it is cheaper than ebonite, and withstands high temperatures better. It is also easily worked.

(2) Resinous type, including shellac, all kinds of resin, copal and other gums.

(3) Bituminous type, i.e., bitumen, asphaltum and pitch.

(4) Wax type, including beeswax, solid paraffin and ozokerit.

(5) Elastic type, including india-rubber, natural and vulcanized.

(6) Oils.

(7) Cellulose, including dry wood and paper, cotton and various preparations.

(8) Silk and animal tissues.

(9) Sulphur.

Bitumen is an excellent insulating material, and is very inert. It melts at a comparatively low temperature, and flows freely at a little over 100° C.

Paraffin wax increases the insulating resistance of fibrous materials, but is easily melted, and is very inflammable. When mixed with linseed oil it forms an insulating material of high disruptive strength.

Shellac and resin, and varnishes containing shellac and resin, are valuable insulating substances, but they give off vegetable acids when heated, and these are found to corrode copper.

India rubber, or simply rubber, is used extensively in the manufacture of cables on account of its high dielectric strength and insulating resistance. It is obtained from a great variety of trees and shrubs in the form of a milky sap which is coagulated by heat, and then forms raw rubber. The finest and best quality is that known as Para rubber, which comes from Brazil. When rubber is heated and mixed with sulphur, part of the hydrogen (its composition being C_5H_8) is replaced by sulphur, and the product is termed vulcanized rubber, a flexible, elastic body also extensively used as the insulating envelope of cables. Pure rubber is expensive, and it deteriorates in time if subjected to moisture, whilst

*From *Electricity*, London.

Digitized by Google

vulcanized rubber oxidizes more or less rapidly and absorbs water to some extent. When rubber is mixed with a high percentage of sulphur and vulcanized for a considerable time, a hard horny substance known as vulcanite, is formed, which is largely used for bases and supports of terminals and instruments.

Telegrams by Telephone.*

On March 1, 1911, arrangements became effective between the Western Union Telegraph Company and the New York Telephone Company which enabled subscribers and patrons of the New York Telephone Company's system to telephone their telegrams, night letters, day letters and cable messages to Western Union offices for transmission and have the charges billed on their telephone bills. Since that time, with the co-operation of the Western Union Telegraph Company, a steady advance in the handling of this service has been made.

It is not necessary for the public to look up the telephone number of the Western Union. The word "Telegram" is used instead of a telephone number, and central office arrangements are perfected which insure the connection of the telephone to the proper Western Union office.

Every one of the 10,874 telephone operators in the 518 central offices knows what to do when she hears the magic word "Telegram" at any hour of the day or night from anyone of the 768,448 telephones served by the New York Telephone Company. Every telephone station is a telegraph station. The telegraph operators take the messages from dictation over the telephone lines. The charges for telegrams are being billed and collected by the telephone company. Subscribers are beginning to look on a telegraph message as a familiar incident of every-day social and business communication rather than as a serious and special event.

The old tendency to think of telegraph blanks and messenger boys as an essential part of the machinery for starting a telegram on its way, or for receiving a reply, will soon be a thing of the past, and the feeling of alarm which thousands of persons of nervous temperament have suffered at the receipt of the yellow telegraph envelope, fearing that it may be the bearer of bad news, is rapidly disappearing as people generally avail themselves of the wonderful convenience of the telegram, the day or night letter, and the cable message as a means of communicating good news and intelligence of all kinds to their friends and business associates. The receipt of the telegram or day letter by telephone will be quite as commonplace an event as the receipt of the social or business letter or telephone message.

Every advertisement has brought an increase in the volume of telegrams handled by telephone. A recent circular enclosed with the telephone bills increased the number of telegrams received over the telephone at the New York office of the Western Union Telegraph Company 60 per cent.

This great added convenience is not limited to subscribers of the company, as the routine provides for receiving telegrams from all public telephones. When telegrams are sent from coin box telephones of the multi-coin type the Western Union operator advises the telephone operator of the amount of telegraph toll, the telephone operator in turn asking the patron to drop the money for the telegraph message in the coin box, together with the charge for the telephone call. Special placards are being placed at these stations explaining the service.

At most of the important public telephone stations equipped with switchboard and booths where the company employs an attendant to handle the business, arrangements have been made to receive written telegrams from the public for transmission, the telephone attendant, as the representative of the telegraph company, collecting the toll and telephoning the message to the nearest Western Union office. This feature has made available to the public eighty-one additional places in and around New York City alone, at which Western Union telegrams and cable messages of every sort may be handed in over the counter.

The telephone company is trying in every way to encourage subscribers and patrons to give the telephone number of the person to whom telegrams are to be sent. Experience has shown that telegrams can be delivered by telephone, in a large majority of cases, without any of the delay incident to the delivery by messenger. Here, again, the public seems to be pleased with the new arrangements. The delivery by telephone incidentally does away, in many cases, with messenger charges.

Attention is being given to the plan of combining commercial offices of the two companies. A number of these joint offices have been established in the up-State divisions. The extension of this arrangement to a large number of other places in the territory is being actively pushed by both companies with every probability that a suitable working arrangement can be effected which will result in increased convenience to the public.

As an instance of the efficiency of the new telephone and telegraph service a case is cited where a telephone subscriber in New Rochelle, N. Y., transmitted a cable message to London over his telephone and received a reply over the telephone without having left his office chair.

Telephone Service on the Isthmus of Panama.—A contract has been entered into between the Panama Railroad Company and the Isthmian Telephone Company, a local corporation organized for the purpose of conducting a general telephone business on the Isthmus of Panama, by which the railroad company will transfer its commercial toll-line business originating at Colon or Panama to the telephone company. The telephone company will at once establish its toll-line service, using the railroad company's circuits out of Panama and Colon. The contract does not include the whole Canal Zone in its scope, and the present arrangement of charging $7.50 a month for commercial service will be continued at all intermediate points.

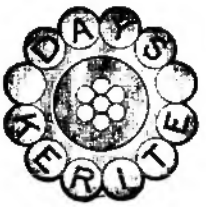
KERITE



INSULATED WIRES and CABLES

DEPENDABLE

Kerite Cables installed upward of 35 years ago, and exposed to deteriorating influences, are giving perfect service to-day.

EFFICIENT

Kerite does not rely upon the rubber in its composition for insulating efficiency. Kerite itself is a compound having superior insulating qualities.

SERVICE

A half century of successful service has demonstrated that Kerite possesses the essential qualities of safety, reliability and economy to an exceptional degree.

The Railroad.

Mr. G. H. Corse, Jr., representative of the Chicago, Milwaukee & Puget Sound Railway in Shanghai, China, has resigned to accept a position in the telegraph service in New York.

Mr. Wilmer S. Bates, night chief of the Northern Pacific Railway, at Seattle, Wash., has resigned, to go into the ranching business in the White Salmon Valley, Washington. Mr. Bates, however, has not become separated entirely from telegraph interests, as he has established a wireless station at his home, by means of which he will keep in touch with the outside world and receive the news of the day.

Mr. E. E. Backus, superintendent of telegraph and signal engineer of the El Paso and Southwestern system, at El Paso, Tex., whose appointment was announced in our issue of September 16, is a native of the Old Dominion state (Virginia), having been born February 10, 1868. In 1883 he began his telegraphic career in New York, and has had a wide experience as a telegrapher and official with telegraph, telephone and railway companies and commercial concerns. At the time of his last appointment he was sales engineer of railroad supplies of the United States Electric Company in its Chicago office.

Telephone Dispatching on Florida East Coast Line.—The Florida East Coast Railway is installing a telephone train dispatching system on its line.

The Burden of a German Telegraph Inspector.—If any one should have occasion to communicate with the assistant inspector of the telegraph department of state railroads in Germany, he should be addressed as the "Eisenbahnbetriebstelegrapheninspektionasistenten."

Meeting of Railway Telegraph Superintendents.—A joint meeting of the Eastern and Western Divisions of the Association of Railway Telegraph Superintendents will be held in Chicago November 23 and 24 to consider matters of interest and importance to the telegraph-telephone branch of the railway service. The practice of handling Western Union reports and other similar business between railroad offices and the telegraph superintendent by railway mail having been objected to by the Post Office Department the matter will receive consideration at this meeting. The members will visit the plant of the Kellogg Switchboard and Supply Company and that of the Western Electric Company at Hawthorne. Other matters of special and general interest will come before the Chicago meeting and a large attendance is looked for. Mr. E. A. Chenery, superintendent of telegraph of the Missouri Pacific Railway, St. Louis, Mo., is the chairman of the Western Division, and Mr. Charles Selden, superintendent of telegraph and general inspector of transportation of the Baltimore & Ohio Railroad, Baltimore, Md., is the chairman of the Eastern Division.

Death of Isaac T. Dyer.

Isaac T. Dyer, superintendent of telegraph of the San Pedro, Los Angeles and Salt Lake City Railroad, Los Angeles, Cal., died in the hospital in that city on October 25 after a lingering illness. He was one of the most prominent and popular railway telegraph superintendents in the country and endeared himself to a large circle of acquaintances through his sterling qualities. He was elected president of the Association of Railway Telegraph Superintendents at the Los Angeles meeting in 1910 and served its interests faithfully and well notwithstanding his impaired health.

Mr. Dyer was born in La Grange, Mo., August 17, 1860. He entered the railway telegraph service in 1876, and two years later accepted a position with the Western Union Telegraph Company at Quincy, Ill., where he displayed considerable ability as an electrician besides being an expert telegrapher. He later filled positions in the Kansas City and St. Joseph, Mo., offices, and in 1889 reentered the railway service in Kansas City, on the Kansas City, St. Joseph and Council Bluffs Railroad. While residing in St. Joseph, Mr. Dyer became a prominent citizen of that place and was a member of the school board for a number of years. He accepted his late position about ten years ago during which time he resided in Los Angeles.

New Telephone Dispatching Circuits on Lake Shore Railway.

The Lake Shore and Michigan Southern Railway has placed another order with the Western Electric Company for enough of its selectors to equip five new circuits. The Lake Shore road is already operating about 1,100 miles of circuits by telephone, and the addition of the five new circuits will bring the total mileage up to about 1,850 miles. The new circuits run from Hillsdale to Lansing, Mich., with a branch from Homer to Dundee, Mich.; from Fort Wayne, Ind., to Jackson Mich., with a branch from Bankers to Ypsilanti, Mich. (thirty-six stations); from Detroit to Jackson, Mich., with a branch from Monroe, Mich., to Toledo, Ohio, and another one from Grosvenor, Mich., to Fayette, Ohio, with a short branch from this line at Lenawee Junction to Adrian, Mich. (forty-one stations).

In addition, a message circuit will be run from Fort Wayne, Ind., to Jackson, Mich., with twenty-two stations. Another message circuit will also be run out of Detroit to Jackson, with a branch off from Lenawee Junction to Adrian, Mich., and Fayette, Ohio (twenty-two stations).

Meeting of T. M. B. A.—The annual meeting of the Telegraphers' Mutual Benefit Association will be held at 4 p. m., November 15, at 195 Broadway, New York. An amendment to the constitution providing that past presidents shall be members of the executive committee will be voted upon and also an amendment making change in date of annual meeting.

Digitized by Google

Magnetic Club Fall Dinner.

The autumn dinner of the Magnetic Club will be held at the Hotel St. Denis, New York, Wednesday evening, November 15. The officers and members of the executive committees of the Old Time Telegraphers' and Historical Association, and the Society of the United States Military Telegraph Corps, have been invited to attend the dinner as the guests of the club, and the following have signified their intention of being present: Hon. Wm. S. Jordan, of Jacksonville, Fla., president-elect Old Time Telegraphers' and Historical Association; Col. Wm. B. Wilson, of Holmesburg, Philadelphia, Pa., president of the Society of the United States Military Telegraph Corps; Mr. Belvidere Brooks, general manager Western Union Telegraph Company, New York; Mr. D. H. Bates, secretary Society of the United States Military Telegraph Corps, New York; Mr. Richard O'Brien, Scranton, Pa.; Messrs. C. A. Tinker and W. J. Dealy, general superintendent of the Commercial News Department, New York.

The out-of-town delegates to the annual meeting of the Telegraphers' Mutual Benefit Association, which is to be held on the afternoon of the same day, have also been invited to attend the Magnetic Club dinner.

Mr. Joseph J. Cardona, 253 Broadway, New York, is treasurer of the club, and all those who expect or desire to attend the dinner should communicate with him not later than November 11.

Our Subscription Contest.

The subscription contest is now waxing warm, and our agents are exhibiting great activity. New subscriptions are coming in in a satisfactory manner, but we desire a great many more before the contest closes. Every man in the telegraph business should be a subscriber and there is a large field yet to be developed by our agents. Each one will find in his own territory many persons who are not subscribers although they may be readers of occasional copies of TELEGRAPH AND TELEPHONE AGE. These should be singled out and argued with systematically and with judicious persistence. The strongest argument an agent can present to prospects is that the paper is educational and contains news and information that are worth many times the subscription price. Our instruction course in the elements of technical telegraphy, which began in the issue for October 16, is a technical education in itself, and could not be obtained for $25.00 elsewhere, yet this is given free to our subscribers.

The conditions of the contest were given on page 594 of our issue for September 1. There are five prizes, as follows: First, $50; second, $25; third, $15, and the fourth and fifth, $5 each. The contest is limited to new subscriptions and renewals only. The total amount received from each agent on this account will decide the contest. In the event of a tie on any one prize, the prize will be divided.

In offices where there is no regular agent for this journal an agency may be established by securing an appointment, and any reliable person can thus enter the contest. An agent in a small office has just as good a chance to win as has the one in a large office, and it is desired that many more new agencies be established. There are many telegraphers throughout the country who are not subscribers, but who ought to be for their own good and agents are urged to exert themselves to the utmost to capture them.

The contest will close December 20, therefore there is ample time for hustlers to enter the lists and make a record.

Electrical Instruments and Testing.

Every one connected with the telegraph and telephone service should know how to test lines and also be familiar with the instruments used in such work. It does not require much study to learn the mechanical operations of this important branch of the service, but of course a knowledge of electrical and mechanical principles involved in the design and construction of the instruments, and of the principles involved in measurements is the source of deep and never-ending pleasure to the ambitious student.

An excellent book on this subject, intended for the practical man, is "Electrical Instruments and Testing," by Norman H. Schneider, with new chapters on testing wires and cables and locating faults, written by Jesse Hargrave, division superintendent of the Postal Telegraph-Cable Company, Atlanta, Ga.

This work tells how to use the voltmeter, ohmmeter, ammeter, potentiometer, galvanometer, the Wheatstone bridge and standard portable sets. The apparatus described is modern and in universal use, and the tests are such as are required daily.

Mr. Hargrave carries the student step by step through the different methods of testing for faults, insulation and conductivity, cable faults, etc., and the simplest language possible is used. The formulas given are explained in the text preceding them, and examples are worked out in simple arithmetic.

This is one of the most practical and useful books on electrical testing instruments and testing that has been published and is fully illustrated with views and diagrams of instruments used in this line of work. Every one who desires to widen his knowledge on electrical matters should have a copy of this book in his library. Even if he never has the opportunity to make an actual test he will learn a great deal from the work that will improve his mind and general knowledge of things electric.

The price of this book is $1.00 and copies can be had of TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York. Any other book on telegraph, telephone or general electrical subjects can be obtained at the same place.

Mr. Edison's Explanation of the Incandescent Lamp.—Mr. Edison has a characteristic way of telling things he knows, and this was referred to recently by Mr. Walter P. Phillips of Bridgeport, Conn., an old time telegrapher and later general manager of the United and Associated Press. In 1876 Mr. Edison attempted to explain the incandescent lamp to a reporter of the "New York Times," F. X. Schoonmaker. "You see, Skooney," he said in his inoffensively familiar way, "the current is generated and is sent out on the wire just the same as it is for the arc lights. Finally, in my system, it strikes these lamps which have, inside the bulb, as near to a vacuum as we can get. You know nature abhors a vacuum and mighty mean of her, too, for if the vacuum were perfect we would never have to renew our lamps. They would hold out to burn until the most belated sinner had steered his wet and sloppy catamaran into port. Now after having given this current a good horse to ride, in the shape of a copper conductor, we drive it through this diminutive filament, in a vacuum too, mind you, Skooney, and do you know what happens? It gets so hot under the collar at being held up, that it first gets red in the face and then grows hotter and crazier until it achieves a white heat, the highest expression of anger of which it is capable. And there you are, you hoary headed old Pennsylvania Dutchman; that is the Edison incandescent light, that you will hear more about before your snowy thatch turns back to the bonnie brown of your boyhood."

Handy Electrical Dictionary.

This little book, of vest-pocket size, is a practical hand book of reference and contains definitions of electrical terms and phrases in use in every branch of electrical science. It is especially valuable for telegraphers and telephonists, and will be found a great aid in the understanding of electrical things and apparatus met with daily. It is thoroughly reliable, having been compiled by an engineer, and it will be found a very useful companion for students and others who wish to broaden their knowledge of electrical matters. It has a marginal index which is very helpful in rapidly finding the word or expression whose definition is desired.

The book is issued in two styles of binding, cloth and red morocco, the prices per copy being 25 and 50 cents, respectively. Address TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

Mr. J. Fletcher, superintendent of the Canadian Pacific Railway Company's Telegraph at Vancouver, B. C., Canada, in renewing his subscription for another year, writes: "It is unnecessary for me to say anything in commendation of TELEGRAPH AND TELEPHONE AGE. Its worth as an up-to-date periodical is well established. But I can say that without it one would soon get into a rut and fall behind. The AGE fills an unique position in the life of every telegraph man."

The Turner Monument Fund.

As the time approaches for the dedication of the Turner Monument at Harriman (formerly Turner), N. Y., the arrangements are beginning to assume definite shape. Large delegations will represent the Association of Railway Telegraph Superintendents, the Old Time Telegraphers' and Historical Association, and the telegraph, telephone and railroad fraternity at large, and the affair promises to be a notable event.

The announcement has just been made by the committee that owing to the development of a flaw in the stone for the monument it will be necessary to get out an entirely new stone, which will delay the dedication of the monument about one month. The ceremonies, therefore, will not take place until about the middle of December, when the monument will be unveiled by Miss Gertrude M. Griffith, daughter of Mr. E. P. Griffith, chairman of the Monument fund. The dedicatory address will be delivered by Mr. Henry D. Estabrook, of New York, who is an orator of wide reputation and ability. Thus the sending of the first telegraphic train order, by Charles Minot, general superintendent of the Erie Railroad, will be fittingly commemorated.

Mrs. E. H. Harriman, of Arden, N. Y., will meet the cost of the stone and its carving. This work is now being done under the supervision of Mr. Charles T. Ford, of Central Valley, N. Y., superintendent of the Harriman estate, and it will be a great credit to the entire enterprise. The bronze tablet, which was designed by sculptor Charles Keck, of New York, is now being cast, and is a handsome and artistic production. It was illustrated in our issue for October 1.

The following named gentlemen constitute the committee in charge: E. P. Griffith, superintendent telegraph, Erie Railroad, New York, chairman; Charles Selden, superintendent telegraph, Baltimore & Ohio Railroad, Baltimore, Md.; J. B. Taltavall, Telegraph and Telephone Age, New York; E. A. Chenery, superintendent telegraph, Missouri Pacific Railroad, St. Louis, Mo.; W. J. Camp, electrical engineer, Canadian Pacific Railway, Montreal, Canada; Col. W. B. Wilson, president Society of the United States Military Telegraph Corps, Holmesburg, Philadelphia; F. J. Scherrer, secretary Old Time Telegraphers' and Historical Association, New York; David H. Bates, secretary Society of the United States Military Telegraph Corps, New York.

Mr. J. B. Taltavall, 253 Broadway, New York, is treasurer of the fund and will be glad to hear from anyone who wishes to contribute.

A portrait of Charles Minot, whose historical train order is to be commemorated by the erection of this monument, was published in our issue for April 16.

The contributions received up to date are as follows: Previously acknowledged, $1,675.49; C. D. Mallery, 50c.; C. L. Bridge, 50c.; James F. Washington, 25c.; M. J. Gallagher, 25c., all of Deposit, N. Y. Total, $1,676.99.

INDUSTRIAL NEWS.

Telephone Protective Devices.—We have received a copy of a catalogue and price list of protective devices for telephone installations manufactured by Siemens Brothers & Company, London, England. It shows various styles of these devices and gives brief descriptions of each.

Making Receivers and Transmitters.—Last year the Western Electric Company consumed 1,500 tons of brass, over 300 tons of steel and 200 tons of rubber and other raw materials in the manufacture of Bell telephone receivers and transmitters. This work required 3,500,000 screws.

Telephone Dispatching on Lake Erie, Alliance & Wheeling.—The Lake Erie, Alliance & Wheeling Railroad has recently placed an order with the Western Electric Company for twenty-two of its selectors, which will be installed between Phalanx, Ohio, and Dillonville, Ohio. This line is 85 miles in length, and the dispatcher will be located at Alliance, Ohio.

Western Electric Company Business.—The Western Electric Company experienced a most satisfactory revival in orders billed out of its factories in September. The gain was 12% and the sales were the largest for that month in the company's history. For the nine months to September 30, Western Electric's gross earnings were 4% in excess of the same period last year, and a total overturn for the full twelve months of $66,000,000 is promised.

Telephone Train Dispatching on Raritan River Railroad.—The Raritan River Railroad has recently placed an order with the Western Electric Company for telephone selectors and associated telephone equipment for its line running from South Amboy, N. J., to New Brunswick, N. J., with a branch from Sayreville Junction to Sayreville, and another from Serviss Junction to Lyles. The dispatcher for these circuits will be located at South Amboy.

Telephone Train Dispatching.—The New York Central Railroad, the first railway in the world to install and put in service selective telephone train dispatching, has recently received from the United States Electric Company of New York 249 selector box outfits which will be used in the extension of its system over twelve circuits. These instruments, as are the others in service on that road, are the Gill bridging telephone selectors and are arranged for ringing the signal bell with the main line battery. The Baltimore & Ohio Railroad, also an extensive user of selective telephone dispatching apparatus of the same make, has placed orders for ninety-six box outfits, equally divided between train wire and message circuit equipment. The message circuit outfit has the intercommunicating features and is equipped for time transmission. The entire order is for the local battery type and in addition an existing circuit of twentyseven main line bells is to be changed to the local battery type. The order includes the company's standard auxiliary apparatus.

German Telephone Literature.—The Siemens & Halske A. G., Berlin, Germany, has issued two handsomely gotten-up pamphlets on "Telephone Exchanges" and "Automatic Telephony." The former is illustrated with excellent pictures of switchboards and other equipment, besides interior views of exchanges in prominent German cities, and the descriptive matter is very clear and complete. The pamphlet on "Automatic Telephony" contains a reprint of the paper of Prof. Dr. A. Raps on the occasion of the dinner of the Elektrotechnischer Verein, Berlin, November 26, 1910. The paper is a very complete discussion of the subject and is profusely illustrated, some of the views being of prominent automatic exchanges in the United States.

Municipal Electricians.

Pensions for Municipal Telegraph Employes.—The city attorney of Los Angeles, Cal., has decided that the employes of the Fire Alarm Bureau and Police Telegraph come under the provisions of the firemen's pension fund.

Automatic Fire Signal.—An automatic fire alarm red light signal has been devised by J. P. Flanagin, of Milwaukee, Wis. It is used in connection with regular street lamps. By automatically showing a red glass disc in a prominent place the approach of fire apparatus is shown, thus giving a free course for its passage.

New Automatic Fire Alarm.—An automatic fire alarm has been invented by Prof. J. H. Funderburg, Lake Charles, La. There are six or seven different styles of the automatic alarm, according to whether it is to be placed in hotels, public buildings or residences. The alarm is caused by the rising of mercury in a small tube when the heat reaches 110 degrees.

New York Telegraphers' Aid Society.

The New York Telegraphers' Aid Society's financial statement for the quarter ended September 6 is as follows:

Balance on hand June 6, 1910		$24,741.43
Receipts		1,457.80
Total		$26,199.23
DISBURSEMENTS.		
Sick benefits	$995.41	
Death benefits	500.00	
Expenses	210.11	1,705.52
Balance on hand Sept. 6, 1911		24,493.71
Total		$26,199.23
RELIEF FUND.		
Balance on hand June 6, 1911		$5,455.71
Receipts		82.70
Total		$5,538.41
Disbursements		$30.25
Balance on hand Sept. 6, 1911		5,508.16
Total		$5,538.41

Conference of Western Union Commercial Managers and Managers at Pittsburgh.

On October 10 a conference of the district commercial managers and managers of the third district, Eastern Division, of the Western Union Telegraph Company, was held at the Fort Pitt Hotel, Pittsburgh, Pa. There were present Messrs. E. M. Mulford, division commercial superintendent; J. A. Hill, division traffic superintendent; W. A. Sawyer, district commercial superintendent; A. C. Kaufman, commercial agent, New York; J. M. Creamer, district traffic superintendent, Philadelphia; L. J. Davey, district manager, Jamestown, N. Y., and G. H. Bernard, local manager of the New York Telephone Company, Dunkirk, N. Y.

At the forenoon session the following programme was carried out: "Practical Suggestions," by J. C. McGrew; "Business Getting," by T. J. Jones; "Pungent Paragraphs," by I. N. Sharpnack; "Joint Telephone-Telegraph Offices," by L. L. Leith.

At the afternoon session the following subjects were considered: "Duties of a Manager," by Preston D. Callum; "Adjustment of Claims and Complaints with the Public," by P. M. Bacon; "Concentration of Mind," by R. O. Walters; "The Message," by G. S. Walters; "Our Reputation," by G. F. Stadtmiller; Demonstration of "Solicitor's Interview"—Mr. Preston D. Callum endeavored to sell day letter service to Mr. George S. Walters, general manager of a wholesale grocery house, Mr. A. C. Kaufman being his assistant.

In the evening dinner was served in the Dutch Room and remarks were made by visiting officials.

During the forenoon session the following cordial message of regret and greeting was received from Mr. A. G. Saylor, general superintendent, New York, and a committee was appointed to draft a suitable reply which was sent to Mr. Saylor:

"I regret that circumstances prevent my being with you to-day. I fully appreciate the efforts that have been made and it is gratifying to know that your splendid organization has brought about substantial results.

"On behalf of the company I wish to thank you individually and collectively for the interest displayed. The policy of the company is so well known that it is only necessary to refer to the fact that it will be fully carried out. I trust that your meeting will be both pleasant and profitable. Please remember me to all who are present."

Among those who took part in the conference were: H. Trent, manager, Bluefield, W. Va.; S. V. King, manager, Charleston, W. Va.; J. A. Miller, manager, Clarion, Pa.; U. W. Boggess, manager, Clarksburg, W. Va.; G. S. Walters, district commercial manager, Clarksburg, W. Va.; J. L. Snyder, manager, Cumberland, Md.; L. E. Swinney, manager, DuBois, Pa.; G. F. Stadtmiller, district commercial manager, and J. C. McGrew, manager, Erie, Pa.; W. T. McWhorter, manager, Fairmont, W. Va.; A. A. Jeunet, manager, Franklin, Pa.; E. R. Collins, district commercial manager, and C. H. Reed, manager, Huntington, W. Va.; R. O. Walters, manager, Jamestown, N. Y.; S. W. Kirk, manager, Johnstown, Pa.; J. F. Callahan, manager, New Castle, Pa.; M. F. Horne, manager, New Kensington, Pa.; A. J. Holland, manager, Oil City, Pa.: I. N. Sharpnack, manager, Parkersburg, W. Va.; G. T. Harris, manager, Ridgway, Pa.; F. W. Clark, manager, Sharon, Pa.; C. N. Reed, manager, Tarentum, Pa.; W. A. Blackburn, manager, Thurmond, W. Va.; L. A. Watson, manager, Uniontown, Pa.; R. C. House, manager, Washington, Pa.; H. Young, manager, Wheeling, W. Va.; J. C. Hale, special agent, Westfield, N. Y., and the following from Pittsburgh, P. D. Callum, division solicitor; E .A. Baird, manager; P. M. Bacon, claim adjuster; T. J. Jones, manager; Earl Burton, district supervisor, M. S.; W. J. Dodge, district traffic superintendent; H. Ratnor, traffic supervisor; L. L. Leith, special agent; L. S. Ward, manager; E. C. Bishop, manager; S. C. Moran, manager; J. K. Javens, solicitor; Henry Abrams, solicitor; Laura M. Ansley, manager, Indiana, Pa.; Mrs. H. B. Sells, manager, Warren, Pa.; Mrs. J. Rawson, manager, East Liberty, Pa., Miss M. A. Campbell, manager, Punxsutawney, Pa.; Miss E. R. McElwee, manager, McKeesport, Pa.

Opportunity for Telegraphers.

The International Correspondence Schools of Scranton, Pa., have probably to their credit a record of a greater number of promotions among commercial telegraph people than all other educational institutes combined. The telegraph operator just starting in business life will find these educational courses an easy path to promotion. Even the expert electrician finds it advantageous to become a student of the International Correspondence Schools.

When it is stated that this school has had hundreds of thousands of students scattered throughout the world all of whom had their knowledge and usefulness greatly increased, the advancement in salaries incident to their increased efficiency is beyond computation.

The International Correspondence Schools are better able today than at any previous period to assist beginners in telegraphy to become telephone and telegraph engineers and all others identified with the telegraph, the telephone and railroad service, and every individual owes it to himself to build up his efficiency and thus to derive the monetary reward which awaits increased knowledge.

Write for particulars to the International Correspondence Schools, Box 885, Scranton, Pa., and you will receive information that will at once prove convincing that it will be to the interest of everyone who wishes advancement to become enrolled among the thousands of students of this very worthy institution.

T. M. B. A. Assessment.—Assessment No. 531 has been levied by the Telegraphers' Mutual Benefit Association to meet the claims arising from the deaths of William B. Robinson at Glen Cove, N. Y.; Charles F. Whittenhall at Sabatha, Kan.; John D. Thompson at Baltimore, Md.; Bartlett F. Whitman at San Luis Obispo, Cal.; Aaron T. Cline at Wheeling, W. Va.; Christian Lorenzen at Brooklyn, N. Y.

LETTERS FROM OUR AGENTS.

NEW YORK POSTAL.

Mr. R. C. Mitchell, in charge at the *New York American* office (days), represented this company on the Glidden automobile tour from New York to Jacksonville, Fla. He returned to New York by steamer.

NEW YORK WESTERN UNION.

Senator W. L. Ives celebrated his seventieth birthday on October 24 and was the recipient of congratulations from many of his friends.

Mr. Martin Durivan, who has been located at West End, Long Branch, during the summer as chief operator, has returned to this office for the winter, resuming his former position.

Mr. John Simmonds of New York, representing the Western Union Telegraph Company, and Mr. Evelyn Harris, representing the Southern Bell Telephone Company, occupied a car in the Glidden automobile tour, between New York and Jacksonville, Fla., last month.

The annual entertainment of the New York Telegraphers' Aid Society for the benefit of the Relief Fund will take place on Tuesday evening, November 21, at the Lexington Ave. Opera House, Fifty-eighth Street near Third Avenue, Manhattan. Mr. James P. Clolery has been appointed chairman for this season and announces that the members of the various committees are making every effort to bring this year's event up to the standard and if possible surpass previous entertainments. The entertainment will consist of high class vaudeville followed by dancing.

PHILADELPHIA POSTAL.

Mr. E. B. Pillsbury, general superintendent, New York, and Mr. Harvey D. Reynolds, district superintendent, Buffalo, N. Y., were recent visitors at this office.

Extra repeaters are being installed by equipment chief C. A. Currier, under the supervision of chief operator E. W. Miller. There has been great need for these extra facilities, and this office is becoming an important repeating point.

Assistant wire chief Francis P. McElroy was married October 24 to Miss Mary T. Coyne, a well-known South Philadelphia vocal soloist. After a tour of California and the Middle West, the couple will reside at 2518 North 19th Street. The entire office staff extended their congratulations and best wishes to Mr. McElroy and his bride, which are heartily joined in by TELEGRAPH AND TELEPHONE AGE.

The great telegraphic song hit, "SEND ME A NIGHT LETTER, DEARIE." Good, catchy music; beautiful title design magnificently printed in colors. Title contains night letter. Sung all over New York, 17c. by mail. All popular music sent by mail.

B. L. BRANNAN, 195 B'way, N. Y.

The Telegraphers' Mutual Benefit Association, 195 Broadway, New York, combines fraternalism with sound business principles; it offers to the telegraph and telephone employe an absolutely safe form of protection, at a cost within the reach of all and lower than can be found elsewhere. Membership is only open to employes in commercial or railroad telegraph or telephone service, and it is manifestly to the interest of those who are eligible and wish to secure life insurance within their means, to secure without delay a certificate for $1,000 or $500, or both, at rates based on present age.

Rare Books For Sale.—Transactions of the American Institute of Electrical Engineers, Vols. 1 to 27, 1884 to 1908, monthly numbers, unbound, in excellent condition. $100. Geo. C. Maynard, U. S. National Museum, Washington, D. C.

OFFICE MANAGEMENT

Report writing—handling of telegraph office accounts—relation of the operator to the public—penmanship—Lectures and practical work.

A new course designed to prepare telegraph operators for advancement—a thorough course by leading experts.

Booklet "H" to any address.

EAST SIDE Y. M. C. A. TELEGRAPH SCHOOL
New York City

An Interesting Letter.—Mr. A. L. Suesman, of Oak Bluffs, Mass., has facsimiles of an interesting letter from General Thomas T. Eckert to Fred Catlin. A copy may be obtained by sending four cents in stamps to Mr. Suesman.

Martin's double or single lever **VIBROPLEX** $7.50. D. C. DeLany, 15 S. Broad St., Atlanta, Ga.

TRANSMITTING MACHINES

I am placing on the market improved YETMAN TRANSMITTING TYPEWRITERS, and KEYBOARD TRANSMITTERS without typewriting features. Am prepared to exchange, repair or rebuild all old machines. Write for catalogues and particulars to

James Uncles, NORTH ADAMS Massachusetts

Rubber Telegraph Key Knobs.

No operator who has had to use a hard key knob continuously should fail to possess one of these flexible rubber key caps, which fits snugly over the hard rubber key knob, forming an air cushion. They render the touch smooth and the manipulation of the key much easier. Price, fifteen cents.

J. B. Taltavall, TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

SOME POINTS ON ELECTRICITY.

BY WILLIS H. JONES.

The Bridge Duplex.

Judging from the number of letters the writer has received requesting further information concerning the bridge duplex, especially at repeating stations, it is evident that some are under the impression that it is quite a complicated affair. No doubt this idea prevails to some extent because of the extra apparatus included in the complete outfit.

Now the bridge duplex holds the same relation to the new standard quadruplex system that the old polar duplex does to the old quadruplex, viz.: it is half of the quadruplex. Both types operate on the same basic principle—direction and quantity of current. The real difference between the two methods is the manner in which the polar relay is connected and the addition of accessories for the purpose of increasing its efficiency. Some of the extra equipment might be called emergency apparatus, inasmuch as it is not really a part of the duplex proper, and which, on a normal circuit, is seldom required. For instance, one piece of the additional apparatus is a "line resistance box," used for the purpose of lengthening the main and the artificial lines equally when, in wet weather or under certain other conditions, the regular duplex voltage or current furnished is too great for the circuit.

With the former polar duplex and quadruplex apparatus, when an E. M. F. of lesser value was required, it was usually customary to shift the circuit to another set supplied with proper voltage. The line resistance box simply renders it unnecessary to go to all that trouble.

Then we have a double knife-blade switch lever which is seldom used and not actually necessary, so far as duplex operation is concerned, but is a very convenient device for shifting the set from Morse to telephone circuits. There is also an extra three-point switch which cuts in or out the compensating resistance coils enclosed in the smaller inverted iron basin placed on top of the table.

At repeating stations tnere is also added a "leak box resistance," the purpose of which is to provide a side path of very high resistance, which path includes a very sensitive polar relay and sounder. This circuit taps the main line current near the contact points of the direct contact point repeater relay and diverts a small part of the current through the relay in this leak circuit. As the signals which the repeater attendant hears in the leak circuit are made by part of the main line current, it is obvious that he can thus tell exactly how the sender's signals arrive and pass through the repeater points.

The signal relays, buzzers and lamps are not part of the duplex proper, but are merely accessories for the purpose of calling the attendant's attention to circuits which require looking after.

The location, resistance values, and necessity for the various lamps, would be almost self-evident if attendants more generally acquired a better knowledge of the normal current required for the operation of each relay, sounder or other magnet in the various circuits.

For example, take the small 2-c. p. signal lamp. It operates short circuited on 26 volts—in other words, it is an Edison 26-volt lamp. As our local circuits are fed by the 26-volt dynamo, it is evident that no lamp is required in that circuit. But suppose it is desired to use this lamp at some point where the local battery voltage is greater. If it is known how much current it requires the lamp can still be used; otherwise it cannot. Now this little signal lamp requires about 350 milliamperes of current, so with any greater value of e. m. f. the current could be reduced to 350 and the lamp would still be available.

Again we know that the normal local current for duplex and quadruplex loops is 250 milliamperes. Hence for the artificial circuit which we substitute for a loop, we must use a lamp that will take the same volume of current. In other words, it must have the same resistance as that of the loop it displaces. As all duplex loops have a uniform resistance of approximately 100 ohms, lamps of that rating only must be used for such circuits.

Digitized by Google

Wherever a lamp of less than 100 volts is found in the 26-volt circuit, it is in series with some magnet that operates on 250 milliamperes of current. The resistance of this lamp plus the resistance of the magnet coil, etc., should amount to 100 ohms.

One exception to this rule is the 80-ohm lamp used in connection with the push button for the one-ohm signal relay. This relay is connected in the local circuit, which has a total resistance of 100 ohms and is unaffected by the normal local current of 250 milliamperes which passes through its coils, because it requires about 350 milliamperes for its operation. So an 80-ohm lamp is grounded on one side, the other side being connected to the push-button for the purpose of shortening the circuit containing the signal relay when the button is depressed, and thus providing the necessary 350 milliamperes of current. This accounts for and suggests the location of the 80-ohm lamp. A good way to avoid confusion is to study the theoretical diagrams of the bridge duplex proper, and the telephone connection and apparatus as shown in the Western Union official instruction pamphlets, separately. They are very simple and easily understood.

Recent Telegraph and Telephone Patents.

ISSUED OCTOBER 17.

1,005,862. Printing Telegraph. To A. S. McCaskey, Chicago, Ill.

1,006,112. Printing-Telegraph System. To A. S. McCaskey, Chicago, Ill.

1,006,344. Printing Telegraph. To M. S. Ayau, New York.

ISSUED OCTOBER 24.

1,006,591. Device for Holding Receivers of Telephones. To E. L. Persons, Concord, N. H.

1,006,615. Central-Energy Telephone System. To C. S. Winston, Chicago, Ill.

1,006,635 and 1,006,636. Space Telephony. To L. De Forest, New York.

1,006,786. Space Telegraphy. To G. S. Piggott, Chicago, Ill.

1,006,833. Telephone Receiver. To W. W. Dean, Elyria, Ohio.

1,007,030. Telephone Transmitter. To A. A. Jahnke, Richmond, Cal.

1,007,031. Microphone Transmitter. To A. A. Jahnke, Richmond, Cal.

1,007,036. Telephone System. To A. D. T. Libby, Elyria, Ohio.

ISSUED OCTOBER 31.

1,007,344. Telephone-System Signaling Apparatus. To J. Erickson, Chicago, Ill.

1,007,373. Bracket Telephone. To W. C. Moeller, Doon, Iowa.

1,007,575. Telephone System. To H. F. Joeckel, Camp Point, Ill.

FINANCIAL.

Telegraph and Telephone Stock Quotations.

Following are the closing quotations of telegraph and telephone stocks on the New York Stock Exchange November 13.

Western Union Tel. Co.	78
Mackay Companies	85½
" " pfd.	73
Amer. Telep. and Teleg. Co.	139

Dividend.—The American District Telegraph Company of New York has declared a dividend of 1 per cent, payable November 15.

Personal.

Mr. P. L. Thomson has been appointed advertising manager for the Western Electric Company at New York, vice Mr. F. X. Cleary, resigned. Mr. Thomson was formerly manager of the Western Electric Company's Pittsburgh house. Mr. Cleary will engage in special advertising and sales-promotion service.

Mr. F. G. Creed, of London, England, inventor of the Creed printing telegraph system, sailed for England on November 8, after a visit of a few weeks in the United States on business. Mr. Creed was accompanied by Mr. R. J. Young, a former telegrapher in the United States and Canada, who is now associated with him in a business capacity.

Mr. William McMaster, vice-president of the Montreal Telegraph Company, Montreal, Que., has been elected president and director of the company to succeed Mr. Hugh A. Allan, resigned. Mr. William Wainwright succeeds Mr. McMaster as vice-president. A member of the Allan family has been at the head of the Montreal Telegraph Company for over half a century.

Postal Telegraph-Cable Company.

EXECUTIVE OFFICES.

Mr. E. J. Nally, vice-president and general manager, is at the present time on the Pacific Coast.

Mr. L. Lemon, division superintendent, New York, has returned from Pittsburgh, Pa., where he spent a week on business connected with the service.

Mr. W. I. Capen, general superintendent of plant, New York, has returned from Florida where he went on a combined business and pleasure trip.

Mr. Henry F. Hawkins has been appointed general agent of the money transfer department of this company at New York, vice Edward S. Butterfield, resigned.

Mr. M. B. Fisher, secretary and treasurer of the Fort Wayne Postal Telegraph Company, Fort Wayne, Ind., was a recent New York visitor. Mr. Fisher is a prominent citizen of Fort Wayne.

Digitized by Google

This company is doing some extensive underground work in Washington, D. C., under the supervision of Mr. W. I. Capen, general superintendent of plant, New York.

An important branch office has been established in the new May building, at the corner of Fifth and Liberty Avenues, Pittsburgh, Pa. It is under the management of Mr. A. D. Wise, formerly of the office at Twenty-first Street and Penn Avenue.

Nelson E. Church, Manager, at New Orleans.

Mr. Nelson E. Church, whose appointment as manager of the Postal Telegraph-Cable Company at New Orleans, La., was announced in our issue of October 16, is a native of Ohio, having been born at Newark in that State on April 8, 1861. He began his telegraphic career in Newark in 1879, being employed by the American Union and Baltimore and Ohio Telegraph Companies. When the former company was consolidated with the Western Union Mr. Church became manager

N. E. CHURCH,
Manager, Postal Telegraph-Cable Company, New Orleans, La.

of that company's office in Newark. He resigned to enter the service of the Baltimore and Ohio R. R. in 1882. After that Mr. Church was at different times in the service of the Bankers and Merchants Telegraph Company and the Baltimore and Ohio Telegraph Company, and when the latter company was absorbed by the Western Union he entered the latter company's service in New York. On January 1, 1891, he was appointed cashier and transfer agent at Pittsburgh, later becoming manager of that office and afterwards superintendent, which position he recently resigned.

The Postal in the Austin Flood.—When Austin, Pa., was destroyed by the flood on September 30, the nearest Postal Telegraph office, in the Pennsylvania Railroad station at Keating Summit, eight miles from Austin, became the headquarters for newspaper men as well as the public. Six circuits were immediately rendered available to Pittsburgh, Philadelphia, Buffalo and New York, manned by three Pennsylvania Railroad operators, Messrs John Hixon, C. E. Butzer and C. S. Simmons, and four Postal Telegraph operators, Messrs. L. J. Reynolds, Frank Burger, B. W. Austin and Joseph Lundy, detailed from nearby points in charge of division operator Daley of the Pennsylvania Railroad, and superintendent Reynolds and manager Newman of Buffalo. Over fifty thousand words of newspaper reports were sent over the wires on October 2, besides a large amount of commercial telegraph business. The fine service and conscientious devotion to duty of the Pennsylvania Railroad and Postal telegraph operators evoked the highest praise and thanks of the newspaper correspondents as well as the public. The work was done under the supervision of superintendent of telegraphs of the Pennsylvania Railroad, Mr. J. C. Johnson.

Western Union Telegraph Company.

EXECUTIVE OFFICES.

President Theo. N. Vail is absent on a business and pleasure trip to the Pacific coast. He is being accompanied by the officials through whose territory he passes.

Mr. Belvidere Brooks, general manager, has gone to Chicago on a business trip. He is accompanied by Mr. G. M. Yorke, engineer, Mr. E. Y. Gallaher, auditor, Mr. Robert E. Chetwood, engineer of construction and Mr. W. N. Fashbaugh, traffic engineer.

Mr. T. W. Carroll, assistant to the general manager, is making a business trip through the Southern states.

Mr. W. H. Baker, vice-president of the American District Telegraph Company of New Jersey, New York, was elected secretary of this company at a meeting of the executive committee November 8. Mr. F. W. Lienau was appointed assistant secretary at the same meeting. The office of the secretary has been moved to the fifth floor of the building.

Mr. J. S. Calvert, superintendent at Richmond, Va., reports the following appointments of managers in the first district, southern division: Mr. J. C. Davis, at Florence, S. C., vice I. L. Goolsby; Miss Veta Richardson, at Blackville, S. C., vice B. F. Leland, who leaves the service; Mr. T. B. Smith, at Bennettsville, S. C., vice Geo. W. Gyles; Mr. W. R. Williamson, at Elizabeth City, N. C., vice Chas. Guirkin, who leaves the service; Mr. G. E. Wood, at Wilmington, N. C., vice E. L. Spooner, who enters the operating department.

Mr. I. N. Miller, Jr., assistant general superintendent, San Francisco, Cal., has resigned.

This company has abolished message delivery charges within city limits in all cities where such charges have been made heretofore.

As far as is known the oldest employe of the Western Union Telegraph Company in point of service is Mr. J. H. Seaborn, battery man at Jackson, Tenn., who began his telegraphic career in 1846 or 1847.

Digitized by Google

E. A. Baird, Manager, Pittsburgh, Pa.

Mr. Edward A. Baird, manager of the Western Union Telegraph office at Pittsburgh, Pa., whose appointment was announced in our issue of October 16, was born in Narrowsburg, N. Y., September 7, 1874. He entered the telegraph service at Warsaw, N. Y., in 1891, and has since that time held the position of manager at Warsaw, Elmira and Binghamton, N. Y. He afterwards became chief clerk to division commercial superintendent E. M. Mulford, district commercial superintendent J. F. Nathan and district commercial superintendent W. A. Sawyer, New York, successively, finally receiving the appointment as manager at Pittsburgh, Pa., as announced. Mr. Baird's duties have been of an executive character all through his business career and he is therefore eminently fitted by experience to fill his new post.

J. S. Berger, Manager, Lexington, Ky.

Mr. J. S. Berger, manager of the Western Union Telegraph office at Lexington, Ky., was born in Catlettsburg, Ky., twenty-seven years ago and entered the telegraph service in 1899 as messenger at the same point. In 1900 he became an operator and worked for four years at various places on the Chesapeake and Ohio, the Norfolk and Western and the Louisville and Nashville Railroads. Mr. Berger entered the service of the Western Union in October, 1904, as manager at Catlettsburg and in March, 1911, he became manager of the Ashland, Ky., office of the same company which position he held at the time of his recent promotion to the Lexington managership.

Augusta, Ga., Western Union Office.

The Western Union office at Augusta, Ga., has long been an important telegraphic point, not because of its large local business alone, but also because its location makes it the largest relay station in the South Atlantic States. These conditions make it necessary that the equipment of the plant, the force of operators and of efficiency must meet the demands. To all of these requirements the company has and is adding as occasion requires. This office relays business for North Carolina, South Carolina, Georgia and Florida and many points outside of this territory. It employs regularly thirty-five operators, not including chiefs and clerical force. A large force of messenger boys is also employed. The equipment is of the most modern type, and includes the latest improved quadruplex apparatus. There are eighty wires running into the switchboard. During the past year the office of the company has been remodelled at heavy cost.

The entire business of the Western Union Company in Augusta is under the management of Mr. L. R. Daniel. He is ably assisted by P. J. McLaughlin as assistant manager and cashier, G. W. Hammell, chief operator, A. Potter, wire chief, W. E. Seward, night chief operator, Charles Smith, traffic chief, C. F. Bradley, repeater chief, and G. T. Rhodes, all-night chief. The company maintains a branch office on the floor of the Cotton Exchange, which is under the management of Arthur T. Carter. He has also two regular assistants.

Philadelphia Conference of Western Union Superintendents and Managers.

A largely attended meeting of representative officials of the Western Union Telegraph Company was held at the Hotel Walton, Philadelphia, October 19. Mr. J. W. Reed, district commercial superintendent, Philadelphia, who presided, opened the session with an introductory address, in which he clearly set forth the purpose of the meeting, and personified the keynote of his address—"Enthusiasm and Optimism"—to such an extent that his hearers caught the spirit, and carried it into their speeches. Every man in the assemblage was made to feel that. in the Western Union, its welfare and destiny, he had a keen personal interest, and upon his efforts depended largely whether or not it would attain to the high position it aims to fill in the telegraph world.

Papers were read as follows: Efficiency of Messenger Service, by Mr. V. J. Albert; Solicitation of Business, by Mr. R. A. Black and Mr. E. H. Shriner; Office Atmosphere, by Mr. C. J. Swartz; Enthusiasm, by Mr. S. Gray; Salesmanship in Selling Service, by Mr. A. W. Springer.

A lively tilt then followed between Messrs. J. M. Creamer, of Philadelphia, and Mr. A. C. Kaufman, of New York, who gave a practical demonstration of how to approach a prospective customer. This feature was very entertaining and instructive. Other speakers were Mr. R. C. Mason who spoke on the relations between telegraph and telephone companies, Mr. G. W. Deetz. on Efficiency in Messenger Service, Mr. E. R. Kidwell, on Scientific Talk, and Mr. W. E. Mears. on facilities in the great fruit growing belt of Eastern Virginia.

A general discussion then followed on the scientific handling of business, which was ably covered by Mr. E. M. Mulford and Mr. J. A. Hill. The handling of newspaper loops was next considered the discussion being participated in by nearly all present.

Other subjects discussed were: Courtesy. by Mr. F. M. Von Nieda, Day Letter Business, by Mr. W. H. Hamilton, General Remarks, by Mr. G. W. Honsberger, How to Secure Customers. by Mr. M. C. Niepling, Messenger Neatness, by Mr. H. A. Hahl, and Quick Transmission of Messages, by Mr. G. O. Bentz.

After the reading and discussion of the papers division commercial superintendent Mr. E. M. Mulford, New York, spoke at considerable length on the financial condition of the company, its determination to perfect its facilities and better the conditions of its employes, and expressed himself as being well pleased with the results obtained by

Digitized by Google

the employes of the commercial department in the fourth district.

Mr. Mulford was followed by Mr. A. C. Kaufman, of New York, who delivered a very interesting and instructive address on business-getting, dwelling particularly on the creation of new business and the importance of rendering prompt and accurate service.

Mr. I. D. Maize was present and spoke in a very entertaining manner concerning the importance of friendly co-operation on the part of telegraph operators.

Those present were: Messrs. J. W. Reed, district commercial superintendent; S. M. Custer, fourth district commercial manager; R. J. Meigs, district plant superintendent; J. M. Creamer, district traffic superintendent; R. A. Black, city manager; E. J. Smith, assistant city manager; E. H. Shriner, M. C. Niepling and H. A. Hahl, commercial managers; R. C. Murray, plant chief; S. R. Crowder, inspector of equipment; R. C. Mason, special agent commercial department; J. S. W. Phillips, inspector; W. G. Patterson, claim agent; F. R. Webb, general traffic chief; H. D. Austin, district traffic supervisor; F. G. Lamb, chief clerk; D. P. Carlin, J. A. MacLeod, W. C. Finan, P. A. Simpson, V. G. Hudgins, J. W. Benckert, E. M. Taney, B. P. Shreve, W. M. Kalmey, of the *Evening Telegraph*, and John Rowles, all of Philadelphia. Messrs. E. M. Mulford, division commercial superintendent; J. A. Hill, division traffic superintendent, and A. C. Kaufman, division commercial agent, New York. Messrs. J. W. Collins, traffic chief, and E. R. Kidwell, Washington, D. C.; Messrs. V. J. Albert district commercial manager; E. S. Anderson, traffic manager, and G. W. Honsberger, solicitor, Baltimore, Md. Messrs. S. Gray, manger, and A. W. Springer, district commercial manager, Wilmington, Del. Mr. C. J. Swartz, manager, Trenton, N. J. Mr. F. G. Seitz, manager, Camden, N. J. Messrs. G. Catherman, manager, and F. M. Von Nieda, district commercial manager, Harrisburg, Pa. Mr. J. F. Firey, manager, Hagerstown, Md. Mr. J. H. Wilson, manager, Altoona, Pa. Mr. W. E. Mears, district commercial manager, Parksley, Va. Mr. W. L. Sullenberger, manager, Lancaster, Pa. Mr. W. H. Hamilton, manager, West Chester, Pa. Mr. G. W. Deetz, manager, Atlantic City, N. J.

The Cable.

Cable Between Trieste and Alexandria.—A company is to be formed in Austria for the purpose of establishing and working a cable between Trieste, Austria, and Alexandria, Egypt.

Cable Subsidy.—The Australasia and China Telegraph Company, Limited, has been given the right to be heard before the United States Court of Claims in its case against the United States for $109,462 and interest as payment of a subsidy guaranteed by the Spanish Government in 1897 for a cable connecting four of the Philippine Islands.

The Telephone.

Extension of Rural Telephone Service.—The Cumberland Telephone and Telegraph Company will make large extensions of its rural lines in Mississippi during the next six months.

Reduction of Telephone Bills Ordered.—The Oklahoma Corporation Commission has ordered the Pioneer Telephone and Telegraph Company to render "adequate service in Muskogee" and that the November 1 bills "be reduced one-third of the customary prices charged."

Protection of Telegraph and Telephone Property in Missouri.—It is a felony in the State of Missouri to injure, molest or destroy telegraph or telephone instruments and property and such offenses are punishable by imprisonment for two years or by fine not exceeding $500.

News Service by Telephone.—The Houghton, Mich., *Gazette* refers editorially to the substitution of the telephone for the telegraph for the transmission of news service, and expresses itself well pleased with it. The paper was compelled to resort to the telephone on account of the increase of telegraph rates made necessary by the law regulating interstate commerce.

Telephony in Japan.—The telephone business of Japan is in charge of the Imperial Japanese government, and there are no private commercial lines. The telephone business is rapidly increasing and it is the intention of the authorities to double the present equipment within six years. In 1906 there were 336 stations and offices and 43,266 subscribers, while in 1910 there were 2,233 stations and offices and 126,720 subscribers.

New Telephone Building in Buffalo.—The New York Telephone Company has awarded the contract for a new central office building in Buffalo, N. Y., to be known as the Bryant-Tupper Central Office. The building will have a frontage of 98 feet and a depth of 93 feet, and will be of fireproof construction. It will cost $90,000. The initial building is designed for one 10,000-line local switchboard, and the plans provide for the addition of three stories in the future if necessary.

Telephone Message Recorders.—Mr. Albert Baumgartner, of St. Gall, Switzerland, is the inventor of an instrument to record telephone communications in the absence of the person called and to reproduce them when desired. It is stated that Mr. E. G. Godfree, of the Victorian Railway department, Victoria, has devised an automatic registering device for telephone calls, which is operated by the removal of the receivers from the hooks of two subscribers when put into communication.

Taxes.—Mr. E. S. Pillsbury, attorney for the Pacific States Telephone and Telegraph Company, San Francisco, Cal., appeared before the United States Supreme Court recently and argued against the collection of the tax imposed upon that company by the State of Oregon under the initiative and referendum statute. Judgment was taken against

Digitized by Google

the company and the Supreme Court of Oregon sustained it. The company then brought the case to the United States Supreme Court.

Fire Alarm By Telephone.—Mr. Walter Maxwell, of Dayton, Ohio, calls attention to the importance of the use of the telephone as a means of extensive fire prevention. "We ought to impress upon the people," says Mr. Maxwell, "the facilities of the telephone for sending in an alarm of fire. The people should be generally informed through the newspapers and other agencies that they are at liberty, free of any charge, to use any telephone to send in an alarm of fire. Once they understand this we thus establish thousands of fire alarm stations instead of the few regular alarm boxes. Another advantage of the notification of fire by telephone is the fact that the firemen may respond and come to the exact place of the fire, thus saving time and of course more efficiently effect the saving of life and property."

Boston Plant Chapter of the Telephone and Telegraph Society of New England.

The third regular meeting of this society was held November 14, in the Auditorium of the Edison Building, Boston, Mass. Mr. I. O. Wright, assistant general superintendent of plant, New England Telephone & Telegraph Company, addressed the Chapter on various phases of the telephone and telegraph business from a plant standpoint.

He discussed the "Opportunity" of the corporation and of the employe brought about by the recent getting together of the American Telephone & Telegraph Company and the Western Union Telegraph Company.

Mr. Wright is one of the "Telephone Pioneers of America," and previous to his entrance into the telephone service in 1890, he was identified with the telegraph interests.

The membership of the Chapter includes American Telephone & Telegraph and Western Union men.

Radio-Telegraphy.

Wireless in Chili.—The government of Chili has contracted for a series of Marconi wireless stations along the coast from Africa to Sandy Point.

Mr. Wm. Marconi.—The King of Italy will soon confer a title upon Mr. William Marconi in recognition of his patriotism.

Wireless Suit.—A suit has been started in the United States Circuit Court at Trenton, N. J., by the Marconi Wireless Telegraph Company, a New Jersey corporation, against the National Electric Signalling Company for infringment of patents.

Wireless Across the Pacific.—Wireless communication was held for a short time on October 5 between the San Francisco operator at Hill Crest and the Hokushu station, Japan, 6,000 miles distant. Hokushu is the most northern wireless station of Japan.

The Arlington, Va., Wireless Station.—The new naval wireless station at Arlington, Va., opposite Washington, D. C., will be in charge of Lieut. E. B. Woodward who has been detached from the battleship *Ohio* for the purpose.

Wireless Corps at Cornell University.—Lieut. W. A. Gilmore, U. S. A., has been detailed to Cornell University as professor of military science and tactics. He will form a wireless telegraph detachment of sixteen men in the signal corps of the Cornell cadet battalion.

Wireless at Liverpool.—Arrangements have been made by which it will be possible for a ship in the River Mersey to communicate with vessels in dock at Liverpool, England. Hitherto this was prohibited, as all messages are supposed to pass through the hands of the postal telegraph authorities.

Cooking Eggs on Ice by Wireless.—Mr. E. J. Rose promises to give a demonstration of the art of cooking eggs on ice by wireless waves at the Los Angeles electrical exposition. If he directs his waves upon cold storage plants consumers may be able to buy their eggs already cooked. It is not stated whether he can cook them in every style.

Wireless on the Atlantic Airship Akron.—It is stated that the wireless telegraph apparatus on the airship "Akron" in which Mr. Melvin Vaniman will attempt to cross the Atlantic Ocean, will have a radius equal to that of any of the largest ocean steamers. Mr. Jack Irwin will be the wireless operator on this expedition.

Wireless Weather Bulletins.—The secretary of the Navy at Washington has issued instructions to all the naval wireless stations on the Atlantic and Gulf coasts to ask for special weather reports on observations from vessels at sea whenever required by the chief of the Weather Bureau. It is expected that the wireless stations will also send out to vessels at sea all weather bulletins which may be of service as a warning of approaching storms.

Wireless for the Philippine Islands.—The Joint Wireless Board, consisting of Secretary C. B. Elliott and several army and navy officers, recommends that a complete system of wireless telegraph be installed in the Philippine Islands for the use of the civil government and the army and navy. The report calls for thirteen principal stations, beginning with Batan Island north of Luzon and extending to Jolo on the south. Also fourteen intermediate and low-power stations are recommended. The estimated cost of installation is $300,000.

Wireless Differences Settled.—It is announced that the patent differences between Marconi's Wireless Telegraph Company, Limited, of England, and the Lodge Muirhead Syndicate, have been settled, and that all of the Lodge patents applying to wireless telegraphy have been taken over by the Marconi Company. Sir Oliver Lodge, the well-known British scientist, it was also announced, has become an associate scientific adviser of the Marconi Company.

The Passing of the Old—Some Interesting Correspondence.

In our issue for October 16 we printed under the heading "The Passing of the Old," an article embodying the substance of a letter from Mr. D. H. Fitch, of Cazenovia, N. Y., an old time telegrapher, which has given rise to the following interesting correspondence between Colonel Robert C. Clowry, of New York and Mr. Fitch:

"New York, October 18, 1911.

"D. H. Fitch, Esq.,
"Cazenovia, N. Y.

"My dear Mr. Fitch:

"I have just read your reminiscences as published on page 681 of TELEGRAPH AND TELEPHONE AGE of October 15.

"Sometime about 1864, I think, I accompanied some United States troops that were sent to North Missouri, and when we reached the Missouri River opposite St. Charles, Mo., we found that the ferry boat was laid up on the St. Charles side, on account of ice. The commander of the troops was very anxious to get them across the river, but there was no telegraph crossing, or, if there had been, it was interrupted. My recollection is that to meet the emergency I went on the engine and by sounding the whistle called 'SC,' the telegraph call for St. Charles, and 'D H F' your initials, as I think you were superintendent of telegraph on the North Missouri Railroad and was at St. Charles at the time. It is also my recollection that the call was answered by you on the locomotive on the St. Charles side and I 'Morsed' you through the whistle to send over the ferry boat. It is barely possible that this may have been a dream of mine, but I think it is true. Have you any recollection of it?

"I remember you as an expert electrician and most competent officer at that time.

"Very truly yours,
"(Signed) R. C. Clowry."

"Cazenovia, N. Y., October 20, 1911.

"Col. Robert C. Clowry,
"New York.

"My dear Col. Clowry:

"Nothing has given me more pleasure than your letter of the 18th. There are few of us left now, and we ought to keep more in touch with each other than we have for many years in the past. Let me say at first that I have not forgotten your kindness to me when I was 'green' fifty-one years ago, now, as well as later when I became more ripe. Your memory in the main agrees with mine.

"On January 1, 1864, Captain Smith sent me to St. Charles as military operator. Very soon after Mr. Sturgeon appointed me train master of the North Missouri Railroad and on June 1 Captain Smith put me in charge of all the line on that road.

"We laid a cable at St. Charles, in 1863, but at the time you speak of it had failed. You knew from experience that no cable could long endure the rapid flow and changing bottom of the Missouri River, and you wisely used high span wires of steel instead. When we laid the St. Charles cable we laid it in V shape instead of directly across. We went diagonally down the river about a quarter of a mile to the middle and then turned and went up to the other side in the same way, hoping that this angle to the flow would relieve the strain, and permit the cable to adjust itself to the changing bottom, and probably it did, but nothing could save it from the snags and drift wood which must catch in the lower bend. Like all others, it failed.

"If I remember right, the time of which you speak was when General Price made his last raid to the North, hoping to take Jefferson City, but did not. Some of his force was on the south side of the river near Washington, only a few miles above St. Charles. One day the Washington ferry boat, which they had tried to capture, came down to St. Charles full of bullet holes—one ball had struck the barrel of a musket in the pilot house, flattened and bent it, but no one on board was hurt.

"As a matter of prudence, we kept our boat on the north side of the river, when not amply guarded, and this was the case on the day of which you speak.

"Assure yourself, it was no dream; it is as clear to me as if it happened yesterday. I was in my office, the only operator in St. Charles. I heard your call and ran to the yard engine to answer it. There never had been any difficulty in reading your 'Morse' and the case was not different then. I got your message by steam whistle without any difficulty, and we did more. I sent to you in the same way a train order for a train on that side of the river, and I well remember how we congratulated each other on our achievement when you got across the river.

"I never want to see another year like 1864. Military transportation is no work for children, even if there are ample facilities and the best of conditions, but when you have to comply, or try to, with the arbitrary and imperative orders of military officers, who know nothing of railroad management, on a road whose equipment is insufficient and badly worn, on a track where the guerillas permitted little repair, is a task which I think I succeeded fairly well in performing or as well as conditions permitted, but I do not wish to try it again. During General Price's last raid I sat at my instrument three consecutive days and nights, and toward the end I had 'Old John' Cantrell wake me on my call and go to another room with me and wake me up there. All of this time I was giving train orders in which there must be no error, and fortunately there was none; the strain, however, made a physical wreck of me. At the end of the year I had to give it up and go home and sleep three months, as I did, worn out at 27 years of age.

"I am glad to know that you are so well and hope you may long continue so. I am quite well

Digitized by Google

—much better than many men of less years. My duties here are light and of a kind which it has always been pleasant for me to do—a sort of a perpetual recreation. I always was an electrical crank and have not recovered.

"Truly yours,
"(Signed) Derick H. Fitch."

Message Blank Holders.

The Western Union Telegraph Company has introduced a convenient means for caring for the several forms of message blanks upon operating tables, this having been rendered necessary through the increase in the number of different classes of service.

A large number of different blanks when placed upon the tables, soon become scattered, presenting an untidy appearance and forming a serious risk of loss of messages. In order to obviate these objections a holder has been designed by the engineer of equipment, Mr. W. E. Athearn. It will care for all classes of message forms now in use, but where an operator is receiving a majority of only one class of message, a larger supply of that form may be placed upon the table near the operator, and the other forms in the holder, where they may be instantly reached when required.

On the front of each holder, is furnished a card holder, into which can be placed a card bearing the wire number, name of office or offices upon same, hours at which such offices are open, and any other information which is necessary.

A wall rack has also been designed. These racks are to be placed at convenient points either on walls or columns allowing one wall rack to approximately each 16 positions.

New Books.

Practical Telephone Handbook and Guide to Telephonic Exchange. By T. S. Baldwin.

This book contains chapters on the use of the telephone, line construction, line materials, locating and correction of faults in lines and instruments, besides much other information of value to promoters, builders and managers of rural telephone lines. It is written in popular language and covers the field of telephony very thoroughly. The book is well illustrated. Price $1.00 per copy.

Operators' Wireless Telegraph and Telephone Hand Book. By Victor H. Laughter.

A complete treatise on the construction and operation of the wireless telegraph and telephone, including the rules of naval stations, codes, abbreviations, etc. The principal systems of wireless telegraphy are described and altogether this book will be found an excellent aid in the study of the art and practice of wireless telegraphy and telephony. It is profusely illustrated with views and diagrams of instruments, etc. Price $1.00 per copy.

Vest Pocket Electrical Dictionary. A practical hand book of reference containing definitions of electrical terms and phrases in use in every branch of electrical science. It is especially valuable to telegraphers and telephonists, and will be found a great aid in understanding electrical apparatus and applications of electricity in general. Price 50 cents per copy.

"Modern American Telephony in All Its Branches," edited by Arthur Bessey Smith. A very complete and up-to-date work on the subject of telephony. It has over 800 pages and nearly 600 illustrations. Price, $2.00 per copy.

Electrician's Operating and Testing Manual. By H. C. Hortsman and V. H. Tousley.

This work gives practical instructions for the management, operation and testing of the more important electrical devices now in use. It deals principally with electrical machinery and apparatus and contains much information of general value to the student of telegraphy and telephony. It is free from higher mathematics and is written in plain, easily-understood language. Liberally illustrated and substantially bound in flexible leather. Price $1.50 per copy.

These books and any others on electrical and kindred subjects, published in America or in foreign countries, may be obtained of TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

Telegraphers of Today.

An excellent opportunity is offered to telegraph people in general to become acquainted with over 600 prominent telegraph officials and others identified with the telegraph, the railroad, the submarine cable service and press associations of the past generation, through their portraits and sketches of their careers as published in "Telegraphers of Today."

This work was issued in 1894 and includes biographical sketches of all the individuals connected with the interests mentioned at that period, many of whom have passed away from their earthly labors. The younger generation, however, will find much of interest in looking upon their portraits and reading of their achievements in life. Many of them are still alive and in harness, in the telegraph and other fields of activity.

This book, which is 11½ x 14 inches in size, was originally published at $5 per copy, but in order to close out the remaining copies we offer them at $1 per copy by express, charges collect.

Send orders to TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

Mr. Aris Brown, chief clerk to W. K. McClarin, district plant superintendent of the Western Union Telegraph Company, Nashville, Tenn., in sending us two subscriptions, writes: "Your paper has proven of much value to me and I am recommending it to all plant employes. I believe your educational course in technical telegraphy will prove of inestimable value to a large class of employes and should be taken advantage of by all earnest students."

Multiple Telegraphy.

In a paper read by Major W. A. J. O'Meara at the recent International Electrical Congress at Turin, Italy, that gentleman described various systems of multiple telegraphy. He divided the systems into four classes employing (1) signalling currents which varied not only in strength, but also in direction; (2) signalling currents of moderately high frequency working in conjunction with others of different frequencies or with ordinary telegraph currents; (3) signalling currents built up of a series of impulses sent at short and very frequent intervals; (4) signalling currents consisting of a number of impulses of varying duration sent at regularly recurring intervals.

The first class is represented by the Morse quadruplex system and its many variations, of which the flexibility had been increased greatly in recent years. The system had been found well suited for small offices, as its maintenance required no mechanical skill and very little electrical knowledge. Its cost was also very low as compared with some other multiple systems. Nevertheless the system still had its weaknesses, owing chiefly to the fact that the direction of current in a line could not be reversed without momentarily having no current on that line.

The second class was represented by the Mercadier system, in which different rates of alternating currents were supplied at the transmitting end to actuate receivers which responded only to one particular frequency at the corresponding terminal station. This system, although not adopted on British telegraph lines, had been subjected to experimental investigation on two or three occasions, and the results had demonstrated its practicability; but it possessed the objectionable feature that serious disturbances were produced on neighboring telephone circuits. In this class were also included the Phonophore and Picard systems.

The third class was illustrated by the Delany system, in which the separate channels were worked by the usual Morse keys, each sending continuously at about twenty-five words a minute. A distributor at each end automatically connected the line to the several corresponding sending and receiving sets for brief but frequent intervals, which obviously entailed the mutilation of the signals before going out to line, and necessitated the use of devices at the receiving end to rectify the distortion. The system worked well for a number of years on several circuits in England, but eventually had to be abandoned because of the more or less imperfect character of the signals. In order to improve the working Mr. S. A. Pollock developed a duplex arrangement of a quadruplex set, which, in addition to providing eight channels, enabled longer segments to be used. The set worked very well indeed, and 400 to 480 messages in the hour were actually handled on a single aerial wire 180 miles in length. The apparatus was eventually abandoned on account, among other causes, of the difficulty in maintaining a sufficiently accurate balance for the speed required on aerial lines in the variable climate of England.

In the fourth class the line was joined at regular periods to the different channels in succession, thus allowing the signals to go out to line without being mutilated. The method originated in the Meyer multiplex, where an eight-key transmitting device was utilized to form a Morse letter in connection with a distributor which sent out the signals to line. At the receiving end each Morse letter was printed across a tape, instead of along it, as was now the general practice. The sending was performed by forming one letter per revolution of the distributor on each transmitting device or keyboard. This arrangement did not present any serious disadvantages, but the received record had to be transcribed from the slip, instead of being written from a sounder, as in the Delany system.

The Baudot abolished the tedious operation of writing from slip, and very soon it displaced the Meyer system. The vast difference in line speed required for a sextuple Baudot and sextuple Delany was most marked, the Baudot requiring only one-fifth of the Delany. The Baudot gave typed characters at the receiving end, and another advantage was the practicability of obtaining separate channels on one wire working quite independently to different stations. The Baudot had been adopted comparatively recently for inland working, but sufficient apparatus was not yet available to carry out any comprehensive scheme involving the most advantageous use of line plant. The system had been adopted on the Continent, and in France it had been developed as a duplex system, which, it was understood, fully met the requirements of that country. In October, 1910, the British post office had installed a quadruple duplex giving eight channels (four in each direction) on an underground line between London and Birmingham, also a double duplex between London and Berlin over a submarine cable of about 500 kilometres (310 miles) in August, 1910. The results obtained on these circuits were eminently satisfactory. It was proposed shortly to install a sextuple duplex system between London and Birmingham, and if the experiment should prove successful, the Baudot system would have proved itself the most expeditious machine-printing telegraph system yet invented for dealing with large volumes of traffic. The Murray multiplex, Munier and Rowland systems, all belonging to the fourth class, were also dealt with.

With a multiplex system the message was dealt with immediately it was received, and corrections were asked for and given at once without any delay. Further, the multiple systems had the great merit of enabling the fullest use to be made of the line time in dealing not only with line, but also with short messages. The general public had in consequence the advantage of a quicker service than was possible with ordinary high-speed transmission systems requiring the preliminary pre-

Digitized by Google

paration of a perforated tape. It seemed probable that future developments in printing telegraphs must follow the lead of the Baudot principle on account of the great advantage in respect of the saving of line time, and from the point of view of simplicity in mechanical details.

Reminiscences by Mr. G. M. Eitemiller.

Mr. George M. Eitemiller, for many years a resident of Detroit, Mich., one of the foremost telegraphers in the United States for the past forty years, in a recent letter to the editor of this publication makes a few observations that are of interest. Among other things he says: "I remember Charles C. Adams, now vice-president of the Postal Telegraph-Cable Company, New York, when he was a youngster at Parker Landing in the "lively oil days" when James B. Coulter, Paul W. Bossart, William Talcott and the writer were the teams on the Parker-Oil City duplex, handling from 2,500 to 3,000 messages during exchange hours, often counting our own checks on messages thrown before us. Where would the "bug" machines and the typewriter come in on that speed? Yet the youngsters of to-day smile in derision when we happen to speak of it. I cannot forget those good old days. I now smile when I recall the Philadelphia "shorts" that Walter P. Phillips and the writer worked out of old 145 Broadway with E. C. Boileau, P. V. De Graw or Charles Moore at the Philadelphia end. Thomas G. Kennedy, the night chief operator, would cut in at the New York switchboard and J. E. Zeublin, the chief at Philadelphia, both listening to us making "Rome howl"—a fifty word gait the whole night until clear. Then Mr. Kennedy would delight in saying: "Now, Fity, go up on Albany duplex and take Shelly. He has a few thousand words for the *Herald*." He would then quietly sneak in on another wire and tell Shelly to "rush" me. Those days I did not care how fast it came rolling in. The faster the better. I often wish for a repetition of them and have the speed I had then.

It is forty-eight years since I started out in the telegraph business (1863). In 1868 I was working in the Pacific & Atlantic office under general superintendent McCargo, of Pittsburgh, now deceased. S. B. Rumsey was manager at Philadelphia. We were in with the Franklin people at No. 45 S. Third Street. J. G. Smith was manager and P. B. Delany, chief operator of the Franklin Telegraph Company. James Shane, Edward Kearney and another man comprised the Franklin operating staff, and William Gove, James Nelson and myself the Pacific & Atlantic. I well remember the gold panic. I stood at the door of the office marking down the fluctuations on a blackboard, while Mr. Delany called out, but I could not hear on account of the noise from the crowd of watchers on the sidewalk. From Philadelphia I was transferred to Pittsburgh for the same company.

A month after the strike of 1870 I went with the Western Union and was placed on the old Western Press circuit where I took press from such "flyers" as O. A. Gurley, William Manning and Comb. Green at Cleveland. In those days press matter was relayed at Cleveland. Later Pittsburgh was hooked on to New York, Fred W. Baldwin, A. E. Sink and others being the senders. We were on a side repeater and had no chance to break. What we could not get was made up out of our heads. I copied the Franco-Prussian and Turko-Russian war news and it took some guessing and close watching of the New York dailies to get these outlandish Russian names properly spelled. When I left Pittsburgh to go South I was relieved by Jules Guthridge. That was forty years ago; it seems like yesterday. We copied everything with a stylus and took ten copies—twelve on Saturday nights. Typewriters were unknown then.

While in Pittsburgh, when it happened to be bad or rainy weather, we were often compelled to cut and relay everything from the West and East, and I was frequently ordered out of bed to help out. I often caught Charles Selden and others of the old Cincinnati crowd at the other end of our circuits; also Charles W. Hammond, William Spink and J. P. Cassidy at St. Louis; Charles Lithgow, William Wallace and Edward Whitford at the Chicago end, and so on. We did not let the grass grow under our feet, either. The wires we worked in those days would not or could not be worked by the present generation. There were no duplexes nor quadruplexes then, and all wires were of No. 8 and 9 gauge, iron. Most of those mentioned have since passed to the "beyond," but I hold their memories fresh in mind and will always have an admiration for them.

Sad Result of Wrong Delivery of a Telegram.—The delivery of a telegram to a man in Australia with the same name as the person for whom it was intended was the indirect cause of the loss of the man's life, together with that of his wife. The telegram was addressed to a man by the name of McKay, requesting him to come to Sydney at once as his mother was dying. The dispatch was delivered to another Mr. McKay whose mother evidently also lived in Sydney. He and his wife took a steamer for that place and the steamer was wrecked, all hands on board being lost.

The Old Guard.—A correspondent desires to know what is meant by the "old guard" in referring to New York members of the fraternity. Our understanding of the term is that it means those members of the profession who were employed in this city prior to January 1, 1880, and they will be regarded as the old guard until 1920 when the limit will be extended to include those employed in the city prior to January 1, 1890, or thirty years previous.

Character Building.

One of the most desirable possessions a human being can acquire is a good character. Such a character is a shining light amid the darkness and is admired by everyone; even those who are inclined to be evil-minded respect a man of character. A man with a good name is generally looked upon as a safe person to deal with; he is reliable and attentive to duty; if he makes a promise he keeps it, and he is generally trusted by his fellow men.

A good character, however, cannot be bought—it is beyond price—and the man who desires it must work for it by conducting himself in an honest and upright manner in all his dealings with his fellow men. Some men pretend to possess a good character and may fool themselves in the belief that they have it, but a man's opinion of himself amounts to nothing if it is not in accord with general opinion. It makes no difference what a man pretends to be, if he does not live his convictions he is a hypocrite — he does not practice what he preaches — and his real character is soon found out. Such a one cannot gain or possess the confidence of upright men—in other words his character is not good.

There is an infinite number of ways to build up a character, but at the outset it should be recognized that it cannot be reared on a false or imperfect foundation. The basis should be honesty, integrity, courage and zeal. Without the practice of these qualities a good character cannot be attained.

A man of good character is honest to himself and to those with whom he has social and business relations; he is attentive and punctual in his duties, and loyal to his friends and business associates—in short, he does for others what he would have them to do for him.

Duty to the employer is a necessary requisite in character building. When a man agrees with a telegraph or telephone company, for instance, to work for it at a stipulated remuneration, he obligates himself to render an equivalent in service. If he fulfills his obligations, and is honest and fair otherwise, he naturally falls in line as a candidate for better positions when men are sought to fill them.

It may surprise many to know that there are positions in the telegraph and telephone services to-day that are actually seeking men to fill them.

Loyalty to the employer and strict performance of duty are essential qualities in personal progress, and the man who makes this his life practice is sure to win in the end. Some men are prone to complain that their worth is not appreciated by their superiors. It is safe to say that in many instances they put too high a value upon their worth. Their work and deeds will determine their fitness, irrespective of what they think about it, and the man who is diligent, honest and wide awake and works for the interest of his employer as well as for his own, is the man who will succeed.

An upright character is therefore a most precious possession and he who would make substantial material progress should not lose sight of the underlying principles of such a character, viz.: fidelity, honesty and sobriety—fidelity to trust, honesty towards his fellow men and complete control of his grosser self.

The companies are constantly looking for men that they can trust implicitly, and he who has a good character back of him cannot always remain in the background.

Organization of Telephone Pioneers.

The telephone pioneers who met in Boston November 2 and 3 to organize an association have good reason to be proud of their work. The meeting was held under the most favorable auspices—the weather was delightful and the enthusiasm and good-feeling were unbounded. The programme was carried out exactly as planned and there was not the slightest hitch, from beginning to end, to mar the schedule and enjoyment.

The delegates felt especially grateful for the liberal entertainment provided for them by the American Telephone and Telegraph Company and the New England Telephone and Telegraph Company and they enjoyed every minute of their time.

Dr. Bell's remarks at the afternoon session were delivered in a very entertaining manner, and he captivated his audience from the start. He was not under any restraint so he talked to the delegates—his children, they might appropriately be called—in an easy, conversational manner, such as he would employ in talking to intimate friends in his own drawing room. His re-

Digitized by Google

marks were full of interest, and being in his own family, so to speak, he told many interesting stories and facts in connection with his early work on the telephone that are not generally known.

The primary purpose of the association is to promote fellowship among its members and in the attainment of this object it has the active and moral support of the most distinguished telephone men in the country. The head of the greatest telephone organization in the world will be the guiding hand of the association during the first year of its existence and no doubt the organization will feel the effect of his wise counsel and active encouragement, and develop into a power for good.

Telegraph Monuments.

From time immemorial men have erected monuments to record notable deeds and achievements in human progress, so that successive generations might know what their ancestors had done. The great pyramids of Egypt, and the Washington and Bunker Hill monuments in this country are examples.

At the present time the erection of two monuments of particular interest to the telegraph world is being carried into execution. One of them is to be located at Berne, Switzerland, to commemorate the founding of the International Telegraph Union, and the other at Harriman (formerly Turner), N. Y., to commemorate the sending of the first telegraphic train order. Both of the events to which these monuments are to bear witness for generations to come have resulted in incalculable benefit to civilized nations, the first by facilitating telegraphic intercourse between the nations of the world and the second by rendering railroad travel expeditious and safe. The chief point of difference between the two projects is that the former is international in character, while the latter is virtually a national movement. The purpose of both, however, is the same, i.e., to furnish a permanent record of the genesis and growth of a great achievement. Stone and bronze are always employed to form such records because they are the most substantial and enduring materials we know of.

In our issue for November 1 we give an illustration and description of the Berne monument, and the Turner monument has been described and referred to in these columns throughout the past year. An illustration of the tentative design was published some months ago, and the accepted design for the bronze tablet for the monument was illustrated in the issue for October 1.

Mr. J. E. Riley, manager of the Western Union Telegraph Company, at Bloomington, Ind., writes: "I think TELEGRAPH AND TELEPHONE AGE is one of the most adapted to the craft of any paper I ever read. I think the correspondence school feature is alone well worth the price of a subscription. I shall certainly recommend it to my associates."

Early Telegraphy in La Porte, Ind.

At a recent meeting of the La Porte County Historical Society at La Porte, Ind., Alfred Weller, of Chicago, Ill., and Charles E. Weller, of St. Louis, Mo., both old-time telegraphers, read papers on the early days of telegraphy in La Porte. The two brothers were former residents of La Porte and were well qualified to discourse on the subject.

Mr. C. E. Weller left the telegraph service in 1870, and spends his summers with his brother Alfred on the old homestead at La Porte. They are both among the earliest of living telegraphers.

Mr. Alfred Weller gave a brief account of the early days of the telegraph in the West, and referred to the Speed Telegraph Company, organized in 1847 by Colonel J. J. Speed, the line being erected along the Michigan Central Railroad. Mr. Weller was the first messenger at Marshall, Mich., being then eleven years of age. The one wire between Detroit and Chicago carried all the business between the East and the West and there was plenty of spare time for the operators to talk and joke among themselves over the wire. In those days a coil of wire and a pair of pliers in the hands of a telegraph operator entitled him to free transportation on the railroad.

Mr. Weller handled election returns in 1848 for the first time, and the people of Marshall were greatly enthusiastic over the fact that the returns were received by telegraph. Mr. Weller received an ovation for his work. The paper was deeply interesting throughout.

Mr. Charles E. Weller followed his brother Alfred with a paper similar in character. He, also, was a messenger in the Marshall office, entering the service at the age of seven years, when Alfred was promoted to be an operator. He told in an interesting manner how he, too, became an operator. In the winter of 1856 Mr. Weller received the first train order that was sent over the wire between La Porte and South Bend, Ind. His last service on the Lake Shore was in the office of Charles Minot who had been appointed from the Erie Railroad to be resident manager of the Lake Shore Railroad.

Both papers were well written and received appreciative compliments.

Trip of Electrical Engineers to Panama Canal.—It is proposed by the Board of Directors of the American Institute of Electrical Engineers to arrange a trip of inspection to the Panama Canal Zone during the coming winter. The excursion will be made on the steamers of the United Fruit Company, sailing from New York and New Orleans.

Well-Sustained Wire Communication.—An authority states that wire communication in the United States is well sustained. We think so too. It requires 35,000,000 poles to sustain our wire facilities.

Digitized by Google

Organization of the Telephone Pioneers of America.

Amid the utmost goodfellowship and enthusiasm over 200 telephone pioneers organized the association of "Telephone Pioneers of America" at Boston, Mass., November 2, in the presence of the distinguished gentleman whose invention made the association possible—Dr. Alexander Graham Bell—and many others of distinction in the telephone field.

The meeting was held at the Hotel Somerset, and the weather during the two days was bright and pleasant. Through the courtesy of the New England Telephone and Telegraph Company and the American Telephone and Telegraph Company, liberal entertainment was provided and excellently carried out, and the first meeting of the pioneers will long remain as a pleasant memory in the minds of those who participated.

At 11 a. m. November 2 Mr. Thomas B. Doolittle called the meeting to order. On motion of Mr. Angus S. Hibbard, General Thomas Sherwin, chairman of the board of directors of the New England Telephone and Telegraph Company, Boston, was appointed temporary chairman, and Mr. Henry W. Pope of New York, temporary secretary.

In taking the chair General Sherwin made a few remarks, dwelling upon the development of the telephone industry and warmly approving the organization of the pioneers. He spoke of the many difficulties that they had overcome in the past, and, in closing, welcomed the association to Boston—the birthplace of the telephone.

Mr. H. W. Pope, after thanking the pioneers for their assistance in the preparatory work of organization, read the draft of the constitution. It was considered by sections and finally adopted unanimously.

The name of the association as set forth in the constitution is the "Telephone Pioneers of America," and the association is formed "for the purpose of recalling and perpetuating the facts, traditions and memories attaching to the early history of the telephone and telegraph system; preserving the names and records of the participants in the establishment and extension of this great system of electrical communication; the promotion, renewal and continuance of the friendships and fellowships made during the progress of the telephone industry between those interested therein, and the encouragement of such other meritorious objects consistent with the foregoing as may be desirable."

On motion of Mr. Hibbard the chairman appointed a nominating committee, naming as members Messrs. Carl T. Keller, of Boston, Mass.; J. E. Farnsworth of Dallas, Tex.; W. R. Abbott of Chicago; C. E. Scribner of New York and J. Robb of New York. On the recommendation of the committee the following-named gentlemen were unanimously elected officers for the first year: President, Theodore N. Vail; vice-presidents, F. H. Bethell, W. T. Gentry, E. B. Field and B. E. Sunny; secretary and treasurer, Henry W. Pope. Executive committee: T. D. Lockwood, J. J. Carty and F. A. Houston.

General Sherwin then, in the absence of President Theo. N. Vail, surrendered the chair to Vice-president W. T. Gentry, who assumed the position with a few appropriate remarks.

The by-laws were then read and adopted.

Letters of regret at their inability to be present were read by Secretary Pope from Messrs. E. J. Hall, New York; C. A. Gates, Dallas, Tex.; Charles Selden, Baltimore, Md.; G. Y. Wallace, Salt Lake City; Robert J. Morgan, New York; G. D. Leverett, New York; G. D. Milne, New York; E. H. Lyon, New York; Frank B. Knight, Dallas, Tex.; Union N. Bethell, New York; Thomas A. Edison, Orange, N. J., and others.

The secretary was authorized to make suitable acknowledgments of these letters, also to the New England Telephone and Telegraph Company, and the American Telephone and Telegraph Company, for courtesies extended the delegates.

The condolences of the association were extended to Mr. Charles R. Truex of New York on the recent death of his son, and the meeting then, at 12 o'clock, adjourned.

The afternoon session was called to order by Vice-president W. T. Gentry, who asked Mr. A. S. Hibbard and Mr. Melville Egleston, of New York, to escort to the platform Dr. Alexander Graham Bell, Mr. Frederick P. Fish, former president of the American Telephone and Telegraph Company, and Mr. Thomas D. Lockwood, general patent counsel. As these gentlemen were conducted to the platform they were given a rousing reception.

Vice-president Gentry then introduced Dr. Bell, who made an extremely interesting address, in which he told many facts in connection with his early work in the development of the telephone. Dr. Bell's address is given in full on other pages of this issue.

Dr. Bell was followed by Mr. Frederick P. Fish, former president of the American Telephone and Telegraph Company, who made an interesting address which referred largely to Dr. Bell's personality and his work.

Referring to the pioneers' association, Mr Fish said: "There were a great many great men in the early days in the telephone business. I will not name them; we all know who they were. But I do not doubt that at that time there was not one name which would have come right to the front, if any one in the business, or any one outside the business who knew anything about it, had been asked to name the man who was doing the most direct, definite and effective work for the promotion of this enterprise. One name would have come to the lips immediately; and, by great good fortune of the company, by the great good fortune of the men in the company, by the great good fortune of the world, that man after a period of rest, during which he grew more and more broad, increased his power and capacity to a marked degree, has come back into the saddle to carry on under vastly better conditions and with infinitely more power and strength of purpose the work of development with which he began so far back in the pioneer days of this sys-

Digitized by Google

tem. We are all to be congratulated that Theodore N. Vail (applause) has had exactly the career he has had and that he came back as he did; and we are to be congratulated on the personality of the man, for he is a leader whom every one will love and follow, because he has the right kind of cordial regard and respect for every man who works with him."

At the conclusion of Mr. Fish's remarks, Mr. Thomas D. Lockwood of Boston made an address in his characteristic style.

"This is going to be a good society," he said. "It is something that was very much needed from the outset—certainly very much needed in the last year or two. We did at one time have an association called the National Telephone Exchange Association, which was organized with certain vague ideas of mutual improvement, and especially of advancement in the telephone business; but as the business went on and as the representatives of telephony gradually learned that standardization was necessary, that it was not possible for every man in every one of the different cities and towns of the United States to have a different sort of a system and a different sort of a switchboard and different kinds of apparatus, that Exchange Association, especially with the maturing of engineering forces in the different companies, grew to be rather a social organization, one in which the greatest good was attained not by the meetings, but by the interchange of conversation and the attrition of views between the members.

"I am sure that there is not going to be a dissenting voice when I say that we are very much indebted indeed to Messrs. Pope, Treux and Doolittle, in whose minds this association first took form, and especially to Mr. Pope, for the assiduity and ability with which he has brought it to this point and gathered so many representative men together." (Applause.)

Mr. Lockwood spoke of his early experiences in telephony; how he became interested in the work and how he became employed by the National Bell Telephone Company.

"I am very glad that I came with the company," he continued, "and that I have stayed with the company, and I am very proud today of my thirty-two years continuous service."

In closing his address Mr. Lockwood said: "I have not said anything about the numerous and wonderful changes in organization or in many other respects, because that has been a little out of my line; but I do want before I close to express on behalf of every one, if you will allow me, the pleasure of seeing Professor Bell here today. (Applause.) It has given some of you an opportunity which you never had before of seeing and hearing him both, which I am sure which you will regard all your lives long as being a very great privilege. His present fame as the inventor of the electric speaking telephone is universally recognized, and is secure; and in this respect he is fortunate and happy, since to comparatively few it is given to be fully appreciated while they remain on the scene. But we are assured that this fame is imperishable, and that it will continue and become more firmly established by the lapse of years, and the passage of time; since millions of telephones in America, and as many more millions in the rest of the world are, not mute, but speaking witnesses to the fact, already attested by time, truth and the courts, that they, each and all, trace their genesis to our fellow member, Alexander Graham Bell." (Applause.)

The meeting then adjourned. The time and place of the next meeting will be determined by the executive committee.

ATTENDANCE.

Aberdeen, S. D.—J. L. W. Zietlow.

Albany, N. Y.—W. B. Butler, W. B. Eddy, E. B. Rogers.

Atlanta, Ga.—W. T. Gentry.

Youngstown, Ohio.—J. P. McGahan.

ENTERTAINMENT.

In the afternoon of Thursday, November 2, the ladies of the party were entertained at the Hotel Somerset by readings by Grace Sanborn Cole, and in the evening the entire party attended the performance of "The Three Romeos" at the Colonial Theatre.

In the morning of Friday, November 3, the members visited the main exchange of the New England Telephone and Telegraph Company, special cars being provided to convey them from the hotel.

After luncheon the delegates were photographed in front of the hotel and at 2 o'clock an automobile ride was taken to Lexington, Concord and other historic points in the vicinity of Boston. Each car was decorated with blue pennants bearing the seal of the pioneers' association in gold. On the return to the hotel there was a demand for these pennants as souvenirs, and the supply was soon exhausted. It is the intention of the Entertainment Committee, however, to mail a pennant to each delegate.

THE BANQUET.

At 7:30 o'clock the banquet was held in the main hall room of the hotel, and it was a most delightful affair and a fitting conclusion to the highly successful and interesting meeting. The large room was brilliantly lighted and decorated on all sides with American flags festooned and looped up in a very artistic manner. At the side of the room opposite the main entrance hung a blue silk banner of the association trimmed with gold. It bore the seal of the association and the dates 1875 and 1911, and underneath were the words "Welcome to Boston," all in gold. Beneath the banner was placed a flag with the coat of arms of Massachusetts. The banner, and the state coat of arms, together with the national colors, formed a very pretty and striking picture.

The seating arrangements were carried out in an excellent manner. Each delegate had a printed list indicating the table at which he was to be seated, and as each of the tables was easily identified by means of large numbers hung on standards, the guests were enabled to go right to their seats without any confusion.

During the dinner an orchestra in the balcony rendered excellent music and a quartette of male voices interspersed vocal pieces with pleasing effect.

At the conclusion of the dinner stereopticon views were thrown upon the screen illustrating the development of the telephone industry and many incidents in connection therewith.

Letters of regret were read from Mr. Theo. N. Vail, Mr. E. J. Hall, Dr. Alexander Graham Bell, Mr. F. P. Fish and Mr. E. M. Barton at their unavoidable absence from the banquet.

During the dinner the party sang various songs written by Mr. A. S. Hibbard and adapted to popu-

Digitized by Google

lar airs, and at the conclusion Auld Lang Syne and patriotic airs were sung by the entire assemblage. There was an entire absence of formality at the banquet, and the enjoyment of the affair was complete.

Much regret was expressed at the absence of Mr. Theo. N. Vail, as his presence was looked upon as being necessary to complete the purpose of the gathering. With Dr. Bell and Mr. Vail present, the entire history of the telephone would have been personified. The banquet was tendered by the American Telephone and Telegraph Company.

A banquet was given to the ladies in the main restaurant concurrently with that given to the delegates, at the conclusion of which they joined the men and were present at the close of the festivities. As the party passed out of the banquet hall each person was presented with a metal model of the original Bell telephone as a souvenir of the occasion. These models were made by the Western Electric Company.

NOTES.

The local reception committee received much praise for the able manner in which it performed its special duties. It consisted of Messrs. W. J. Denver, chairman; A. N. Bullens, secretary; E. K. Hall, E. W. Longley, C. T. Keller, G. H. Dresser, F. P. Valentine, I. O. Wright, F. W. Story, J. H. Barry, T. E. Parker, N. W. Lillie, T. J. Feeney and Henry McDonald.

Mr. A. N. Bullens was in charge of the registration and information bureau at the Hotel Somerset and he was highly complimented for his unselfish devotion to the cause.

The New England Telephone and Telegraph Company and the American Telephone and Telegraph Company generously provided the services of stenographers, writing materials, postage stamps and local and long distance telephone service free to members and guests.

The members received a neat little pamphlet giving a brief outline of points of interest along the route of the automobile ride to Lexington and Concord Friday afternoon. It was historical in character and very helpful in identifying the principal points as they came into view.

Badges were handed to the members after they had registered their names in the association roster. The badges were made of blue satin ribbon with the association's triangular seal pendant from a loop, below which the words "Boston, Mass., Nov. 2-3, 1911" were printed in gold. The pin was of unique design. The name of the delegate was inscribed in a panel, above which the word "Hello" was stamped out of the metal and the word "Speaking" likewise cut out underneath the panel, thus reading

"Hello
John Jones
Speaking"

The seal is triangular in shape and of gilt metal. Along the three edges are the words "Telephone Pioneers of America," and in the center of the triangle is the familiar telephone blue bell with the figures 174,465 (the number of the original Bell patent) on the rim.

EXHIBITS.

A very interesting exhibit was made of historical documents, apparatus and models at the back of the convention hall.

Mr. E. T. Holmes of New York made a very extensive display of early telephone subscribers' lists in the principal cities, photographs of early apparatus, exchanges, circulars, announcements, etc. The names of the subscribers were in each case all contained on one sheet.

Mr. Holmes also distributed large cards containing an illustration of the original telephone exchange switchboard (Boston, May, 1877) together with a facsimile reproduction of a letter from Mr. Thos. D. Lockwood, dated August 5, 1884, asking for the loan of this historical board for exhibition at the International Exhibition of Electricity. On another card were facsimile reproductions of the first printed lists of telephone subscribers in the cities of Boston and New York.

Mr. J. J. Ghegan, of New York, distributed among the delegates a facsimile reproduction of the directory of the Newark Telephone Exchange, Newark, N. J., dated May 1, 1879. Mr. Ghegan was then manager of the Exchange.

The New England Telephone and Telegraph Company made a very complete exhibit of historical apparatus, prints and a large variety of documents pertaining to early telephone work. Parts of Dr. Bell's original telephone of 1875 and various other pieces of early apparatus were shown, together with illustrations of the same complete. A showcase contained many articles and documents of great historic interest and two large panels set against the wall held various instruments, transmitters, receivers, switchboards, etc., illustrating the refinements which have taken place since the early days. The New England company also showed interesting models of short lengths of sleet-laden wire cut from a telephone line in Boston after a snow, rain and sleet storm on February 1, 1898. The wire was encased in a mass of ice 3⅝ inches in diameter, the whole weighing 3.2 pounds per foot.

Campaigning by Telephone.—Several society women in Brooklyn, N. Y., utilized the telephone very liberally in electioneering in behalf of a Brooklyn candidate for the Supreme Court. It is stated that they sent in over 100,000 telephone calls in carrying on this work.

Telephony in Russia.—Telephone connection between St. Petersburg and Berlin is under the consideration of the Russian Post and Telegraph Administration. The Russian Administration of Posts and Telegraphs has applied for powers to lay an additional telephone line between Moscow and St. Petersburg.

PIONEERS OF THE TELEPHONE.

THE organization of the Telephone Pioneers of America in Boston November 2 and 3, was successfully effected and much enthusiasm and good feeling characterized the first meeting. In this issue we present the portraits of many of the pioneers. It was our original intention that each portrait should be accompanied by a brief biographical sketch of the subject, but on account of the number and importance of these records, we have been compelled owing to space limitations to depart from the original plan and adopt the one herewith carried out, reserving for future issues the individual use of engravings and sketches in full. In our issue for November 1 we presented full page photogravure pictures of Dr. Alexander Graham Bell and Mr. Theodore N. Vail. The pictures here presented include many of those who assisted in the development of the telephone industry.

ANGUS S. HIBBARD,
Advisory Relation Executive Department, American Telephone and Telegraph Co., New York (1881).

HENRY W. POPE,
Special Agent, American Telephone and Telegraph Co., New York, and Secretary Telephone Pioneers of America (1877).

THOMAS B. DOOLITTLE,
Retired, Branford, Conn. (1877).

CHARLES R. TRUEX,
Special Agent, American Telephone and Telegraph Co., New York (1879).

The Birth of the Telephone.*

Mr. Chairman and Gentlemen: This is a great day for me—the first meeting of the Telephone Pioneers of America and of the world. It gives me great pleasure to meet with you all today; and, yet, there is a feeling of sadness about it. I am the first telephone pioneer, and my memory goes back to the very beginning; and I miss the faces I remember so well, the faces of the old pioneers, whom I wish were here today. The Association is fortunate and the telephone system of America is fortunate that one of these old pioneers is at the head of matters today—Mr. Theodore N. Vail (applause), that great organizing mind that presides over the destinies of the telephone system of America. (Applause.)

I feel it a little presumptuous upon my part to try to speak of the telephone to telephone men. (Laughter.) You have all gone so far beyond me! Why, the little telephone system that I look back upon—what is it compared to the mighty system that goes through the whole extent of our country today? It is to you that this great development is due, and I feel that it behooves me to speak very modestly of the little beginning that led to this great end. I cannot tell you anything about the telephone. I cannot speak to you about undulating current, intermitting current and pulsatory current. I belong to the past, you belong to the present; and it occurs to me that perhaps the most useful feature of my address today might be to call to your minds some of the notable events of the past that preceded the commercial organization and development of the telephone. That is a matter upon which I can give information; that is the point on which many of you may be weak. You know all about many of the later developments; you may not be so familiar with the earlier ones.

The period that marks the incipiency of the telephone was the years 1874 to 1877. It was in 1877 that the telephone really began its commercial career. I shall leave the time after that period to my friend, Mr. Lockwood, and shall deal chiefly with the points that preceded 1877. Of course, in dealing with this period of the history of the telephone I shall have to be somewhat personal, for it all centered upon me in those days.

From 1873 until the beginning of 1876 I was a resident of Salem, Massachusetts, and came into Boston every day for my professional work. Then I would spend my summer vacations in Canada, at Brantford, at the home of my parents. So these three places—Salem, Boston and Brantford—are concerned in the early days of the telephone. Boston is *par excellence* the home of the telephone, for it was here that all the apparatus was made and where the important experiments went on. Brantford, in Canada, was my thinking place, where I would go and spend my summer holidays and look over the line of experiments that had been made in Boston and plan for the future. I generally went to Brantford about the middle of July, stayed there during the summer and was back in Boston the first of October.

And so it happened that in the summer of 1874, during my visit to my father's house in Brantford, Ontario, considering myself and discussing with my father the numerous experiments I had made in Boston relative to the reproduction of musical sounds by electricity for the purposes of multiple telegraphy, the thought of the membrane telephone was elaborated. So that the conception of the telephone originated in Brantford, Ontario, in the summer of 1874. You are all familiar with it. It was practically the same instrument that was shown in the patent that is marked upon our little memento here. It was a theoretical conception of a magneto telephone, a very daring conception, if I may be allowed to say so—that the vibrations of the voice might create electrical impulses like the aerial impulses, and produce an audible result at the other end. To tell you the truth, as a practical man, I did not quite believe it; as a theoretical man, I saw a speaking telephone, but theoretically we had the means of transmitting and reproducing speech in distant places. But it really seemed too good to be true that you could possibly create electrical impulses that would amount to any practical purpose by the action of the voice itself.

And so, on my return to Boston in October, 1874, and all through that winter and through the spring of 1875, instead of making the apparatus and trying it I was trying to devise methods of increasing the strength of these electrical undulations. I was working at what is now known as the variable resistance method. That is shown very well in a letter that I wrote to Mr. Hubbard on the fourth of May, 1875, when I was experimenting on the passage of a voltaic current through a vibrating wire, with the idea that the variation of tension in that wire, by producing variations in the resistance of the circuit, would produce the electrical undulations that I desired.

From the summer of 1874 until June 2, 1875, the development of the telephone was delayed by this thought, that the magneto-electric impulses would not be sufficient by themselves and would require a battery current.

Then came the discovery, with which you are all probably familiar, that a magneto-electric current would produce by itself sonorous effects at a receiving station and you may remember the plucking of reeds that went on that celebrated June 2, 1875. In a moment all the difficulties in the way of the practical solution of the telephone disappeared, and orders were given at once to construct the membrane telephone that was conceived in Brantford in 1874. When it was first tried it was somewhere about the end of June or July 1, 1875. We have present records of experiments on July 1, 1875, and I well remember these experiments. We had only one membrane telephone, and the receiver was one of the old tuned reed receivers. It was held up to the ear. You crammed the armature against the ear to dampen its vibrations. I was listening at that armature while Mr. Thomas A. Watson, my as-

*Address of Dr. Alexander Graham Bell before the Telephone Pioneers of America, Boston, Mass., November 2.

Digitized by Google

sistant, was down in the basement of Charles Williams, Jr.'s, building, 109 Court Street, shouting at the end of the telephone, and then we changed places. I may say that I heard nothing. Then Mr. Watson went downstairs to listen, and I went upstairs to speak, and while I was speaking Mr. Watson came rushing up the stairs in a state of great excitement, saying, "Why, Mr. Bell, I heard your voice very distinctly, and could almost understand what you said." (Laughter.) Well, that was gratifying, but it would have been still more gratifying if I could hear that, too. You see, Mr. Williams' workshop was a very noisy place. Mr. Watson was accustomed to that noise and could hear a good deal better than I. I was more accustomed to throwing out my voice than Mr. Watson, so that he had the advantage of me in hearing and I had the advantage of him in speaking. The results would be considered very unsatisfactory at the present time; yet, encouraged by the results, poor as they were, I went ahead immediately to prepare specifications for a patent. In September, 1875, I was at work upon the specifications of the now celebrated patent. In October, 1875, the patent was completed. But it was not filed in October, 1875. A long delay ensued, because I was so imbued with an idea of the value of this great invention that I was not satisfied to take out patents for America alone—I must take them out for every country on earth. But that, you know, required money, and I did not have the money. Mr. Saunders and Mr. Hubbard, who were associated with me and carried on my experiments, paid the cost of my experiments and of the American patent. They were too wise to touch foreign patents. So I had to go ahead and see what I could do to get this great patent taken up abroad, and that caused great delay. I went up to Canada to interview friends in Canada, and at last made an agreement with the Hon. George Brown, who was at one time Premier in Canada, that he and his brother, Gordon Brown, would take out patents in England, and perhaps other countries, on one condition—that I should not file my application for an American patent until I had word from them that it would not interfere with the applications abroad. And so it was that the American patent dragged on for months, until at last Mr. Hubbard just said a quiet word to my solicitors in Boston: "It is no use waiting longer for Mr. Brown; just you put in the patent." And the patent was filed without my knowledge or consent. It is very fortunate that he did so. It saved a great deal of trouble and interference in the patent office, and so forth, and that is the patent on which the whole telephone system of the United States has been based.

I think it might be well to speak of a few of the more important points. The patent was filed February 14, 1876; it was granted March 3, 1876. I was in Washington at the time when it was allowed. I know it was allowed on March 3, 1876, because that happened to be my birthday, and it came to me as a sort of birthday present.

After the granting of the patent came a period of publication, and I want to speak now of a very curious thing. In the case of new inventions we are generally led to believe that the public is ready to swallow anything, but that grave scientific men are the most skeptical of all. I found just exactly the opposite to be true in the case of the telephone. The public generally and the business men of the country were very slow to perceive any value in the telephone. The scientific world, on the other hand, took it up at once. My first paper upon the subject was delivered here in Boston before the American Society of Arts and Sciences on May 10, 1876. Then I was invited to lecture before the Society of Arts at the Institute of Technology, on May 25, 1876. Then came a very notable event, which I shall speak of very slightly, although it really forms the basis for the knowledge by the world of the telephone. It was the Centennial Exhibition, in 1876. Mr. Hubbard and Mr. Saunders, who were financially interested in the telephone, wanted this instrument to be exhibited at the Centennial Exhibition. In those days—and I must say even up to the present time I am afraid to say it is true—I was not very much alive to commercial matters, not being a business man myself. I had a school for vocal physiology in Boston. I was right in the midst of examinations. My pupils, those studying under me, were studying to become teachers of the deaf, teaching speech to the deaf, and I could not be bothered at that time by having to go to Philadelphia and attend the exhibition. However, we found, in connection with the exhibition, that all the apparatus involving a necessity for quiet was to be examined on Sunday, June 25; and so it was urged that Sunday would interfere less with my professional pursuits than another day. I agreed, therefore, to go down and spend Sunday, and no longer. I could not possibly stay any longer than that while in the midst of my examinations. So I went down to Philadelphia, growling all the time at this interruption to my professional work, and I appeared in Philadelphia on Sunday, the 25th. I was an unknown man and looked around upon the celebrities who were judges there, and trotted around after the judges at the exhibition while they examined this exhibit and that exhibit. My exhibit came last. Before they got to that it was announced that the judges were too tired to make any further examination that day and that the exhibit could be examined another day. That meant that the telephone would not be seen, for I was not going to come back another day. I was going right back to Boston.

And that was the way the matter stood—when suddenly there was one man among the judges who happened to remember me by sight. That was no less a person than His Majesty Dom Pedro, the emperor of Brazil. I had shown him what we had been doing in teaching speech to the deaf in Boston, had taken him around to the city school for the deaf and shown him the means of teaching speech, and when he saw me there he remembered me and came over and shook hands and said, "Mr. Bell, how are the deaf mutes of Boston?" I said they were very

Digitized by Google

well and told him that the next exhibit on the programme was my exhibit. "Come along," he said, and he took my arm and walked off with me—and, of course, where an emperor led the way the other judges followed. (Laughter.) And the telephone exhibit was saved.

Well, I cannot tell very much about that exhibit, although it was the pivotal point on which the whole telephone turned in those days. If I had not had that exhibition there, it is very doubtful what the condition of the telephone would be today. But the emperor of Brazil was the first one to bring that situation about at that time. I went off to my transmitting instrument in another part of the building, and a little iron box receiver—you probably all know what it was from diagram—was placed at the ear of the emperor. I told him to hold it to his ear, and then I heard afterwards what happened. I was not present at that end of the line. I went to the other end and was reciting, "To be or not to be, that is the question," and so on, keeping up a continuous talk. I heard afterwards from my friend, Mr. William Hubbard, that the emperor held it up in a very indifferent way to his ear, and then suddenly started and said, "My God! it speaks!" And he put it down; and then Sir William Thomson took it up and one after another in the crowd took it up and listened. I was in another part of the building shouting away to the membrane telephone that was the transmitter. Suddenly I heard a noise of people stamping along very heavily, approaching, and there was Dom Pedro, rushing along at a very un-emperor-like gait, followed by Sir William Thomson and a number of others, to see what I was doing at the other end. They were very much interested. But I had to go back to Boston and couldn't wait any longer. I went that very night.

Now, it so happened there, that although the judges had heard speech emitted by the steel disc armature of this receiving instrument, they were not quite convinced that it was electrically produced. Some one had whispered a suspicion that it was simply the case of the thread telegraph, the lovers' telegraph, as it was known in those days, and that the sound had been mechanically transmitted along the line from one instrument to the other. Of course, I did not know about it at that time; but when the judges asked permission to remove the apparatus from that location I said, "Certainly, do anything you like with it." But I could not remain to look after it; they had to look after it themselves. My friend, Mr. William Hubbard, who had kindly come up from Boston to help me on this celebrated Sunday, the 25th of June, said he would do his best to help them out, although he was not an electrician. He knew nothing whatever about the apparatus, beyond being in my laboratory occasionally, knowing me well. But he undertook to remove this apparatus and set up the wire under the direction of the judges themselves. So they had an opportunity finally of satisfying themselves that speech had really been electrically reproduced.

Sir William Thomson's announcement was made to the world in England, before the British Association, and the world believed—and from that time dates the popular interest in the telephone.

That was the 25th of June. Of course, the judges and others were anxious to know whether this thing would operate on a long line. Experiments had been made from one room to another in a building; but that was not quite as satisfactory as having one telephone in one place and another in another a hundred miles off. So I was asked whether I would venture to try the instrument between Boston and Philadelphia. Well, I, in my ignorance of the conditions, said, "Of course, yes." So when I went to Boston I began to consider, "Now, what are we going to do? These instruments are only prepared for short circuits." So we began to make experiments in Boston to fit the instrument for use on a longer line. I knew that we must have many turns of quite fine wire in the instrument; so I had such instruments constructed, and then the Atlantic & Pacific Telegraph Company in Boston kindly lent me the use of their wires for experiment. On July 7, July 9 and July 12, 1876, attempts were made to use the telephone upon various circuits from Boston to New York, from Boston to Rye Beach, and other places, but, unfortunately, with poor success. We did not get any vocal sounds on these circuits, although with two instruments, one in one room and another in another room of the Equitable Building and a circuit to Rye Beach, we did get some audible effect. But still the results were unsatisfactory where the undulating current was employed. We tried the intermittent current. I had a parlor organ and made contact with New York and asked the operator to listen and see if he could hear anything. I played tunes on the parlor organ, and he was asked if he could hear anything, and he said, "Yes." "What was it?" "Yankee Doodle." He could hear tunes, but that was really the only result of importance obtained in those trials of July 7, 9 and 12, 1876.

Sir William Thomson was present at later trials, and I presented to him a telephone that we used on that occasion, and it was taken to England and bothered me exceedingly in telephone litigation at a subsequent time. The owners of my English patent had to disclaim everything that was shown in those instruments. But it fortunately happened that the receiving instrument was one of those old Centennial box receivers with the metallic lid, which in this case was one of ferro-type iron, and when I gave this instrument to Sir William Thomson I was afraid he would lose the armature, and so I had Mr. Watson catch the armature down at one point to the magnet, to hold it in place. Sir William just threw the whole thing into his trunk without taking it off, and when it arrived in England the armature, instead of being flat, was cocked up like that. Well, that saved the English patent. (Laughter.) Everybody got the idea that the vibration was from this cocked-up thing. The English patent showed the cocking up of the armature. When it finally came before the Supreme Court of

Digitized by Google

England, when they were deciding the case, the thing looked rather slim, according to the English law. The shreds of the patent were there—nothing was left but the metallic diaphragm. But they made a very singular construction. They said, according to a very benevolent construction of the law, as they construed it that it did not interfere with the patent for metallic armature, and the patent was saved! (Laughter and applause.)

That brings me up to July 12, 1876. Then came my summer vacation of 1876. I went up to Brantford, Ontario; I prepared a whole lot of apparatus, telephones with coils of different kinds, high resistance coils and low resistance coils, long coils and short coils, and I carried them up with me to Brantford, Ontario, and continued attempts to get in touch with long distance lines. The Dominion Telegraph Company of Canada kindly lent me the use of its wires, and I look upon one experiment there as of very great importance. It was an experiment made in August, 1876. The transmitting instrument was in Paris, Ontario; the receiving instrument, the Centennial iron box receiver, was in Brantford, at a distance of eight miles from Paris; and the battery on the circuit was in Toronto, about sixty miles away. So we had a circuit of somewhere from sixty to seventy miles. The transmission went one way only, but speech was transmitted, and that was the first time speech was transmitted between persons at a distance of several miles. But it was only one way; the person at the other end could not reply, but had to telegraph back by another wire. But by August, 1876, quite a number of experiments that attracted attention were made on the wires of the Dominion Telegraph Company. There was one experiment between Brantford and Mt. Pleasant, a distance of about five miles, and then I gave an exhibition from my father's house at a country place four or five miles from Brantford, known as Tutelo Heights. It was about a quarter of a mile from the house to the nearest telegraph line. We got a lot of stove pipe wire, cleaned the town out of stove pipe wire, and took the wire on the fence from my father's house to the corner of the Mt. Pleasant road, and then attached it to the telegraph wire leading into Brantford. Then I had some friends in Brantford who spoke, sang and recited into the membrane telephone, while a large number of guests at my father's house at Tutelo Heights listened to the transmission; and on that occasion also three voices were transmitted simultaneously. I had three mouthpieces made for the membrane telephone and three persons sang to the same telephone.

So those experiments at Brantford were the first experiments that were really successful in transmitting speech from one place to another at a distance, but they were all one-sided, not reciprocal.

The first reciprocal communication occurred after my return to Boston in October, 1876. On October 9 occurred the first conversation by telephone between persons separated by miles of space. This was on the Walworth Manufacturing Company's line, connecting its factory in Cambridgeport with the office in Boston. It was not a very long distance, probably two and one-half miles, but free communication was carried on, and I think that was an historical occasion. Mr. Watson was at one end of the line and I was at the other, and we kept a record of what passed. I noted what I said and I noted what I thought I heard him say, and the parallel columns were reported in the newspapers, especially in the Boston Advertiser, October 19th. I think that was the first time that conversation had actually been carried on between two persons separated by miles of space. The space, however, was not great, only about two and one-half miles.

And so we went on during 1876 with experiments, trying to increase the distance at which results could be obtained. For that purpose the Cambridge Observatory offered its services. They had a private line from Cambridge to Boston for transmitting time signals from the Cambridge Observatory, and through Professor Rogers I had the use of that line at night, when it was not needed for time purposes. I had it connected with my laboratory and by night made experiments between the Cambridge Observatory and Boston, trying to ascertain the conditions fit for telephone service on long lines.

Then came a really noteworthy period of experiments on the lines belonging to the Eastern Railroad Company. An experiment was made on November 26, 1876, in which conversation was carried on between myself, in Boston, at the Eastern Railroad depot, and Mr. Thomas A. Watson in Salem. We had increased the distance to eighteen miles. Then we experimented on a line that led to North Conway, 143 miles away, so that Salem was a way station to North Conway. That was a very notable extension. It was determined that we should send a man to North Conway, and Mr. Watson went up to North Conway with a stack of apparatus, with all sorts of modifications. Now that we had a chance of trying it out on a 143-mile circuit we were determined to take advantage of it, if we had to spend all day and night on it. All sorts of apparatus was carried. I was in Boston and he in North Conway. I think that was really the most important experiment that had been made in connection with the free commercial stage. This experiment was on December 3, 1876, when we had a free communication between Boston and North Conway.

Then we tried varying the coils, trying small wire, thick wire, long coils, short coils, tried it with and without a battery; and as a result of the experiments we gave up the battery and took to the magneto telephone alone, in the laboratory.

That takes us up to the end of 1876. There is hardly anything more I can tell you about it before it came into commercial use. On January 13, 1877, I gave a lecture on the subject at the Philosophical Society in Washington. On January 31, 1877, there was an experiment here in Boston that attracted a good deal of attention at the time, although it did not compare with the other experiments in importance. It was a communication between the rubber

Digitized by Google

shoe factory and the residence of Mr. Converse in Malden, but it attracted a great deal of public attention to the telephone. On January 21 there was a public exhibition on the line of the Eastern Railroad, in which no battery was used. Conversation occurred between Boston and Salem; and by and bye, at about that time, in the early part of 1877 or the end of the year 1876, a rather interesting circumstance took place. I had among my students at Boston University a young Japanese student named Tsawa. He came to me for the purpose of studying the pronunciation of English. Of course, when he heard about the telephone he became very much interested. He said, "Mr. Bell, will this thing talk Japanese?" I said, "Certainly, any language." He seemed very much astonished at that, and said he would like to try it. I said that he could try it, and he went to one end of the circuit and I stood at the other. He talked Japanese, and I reported the result to him. He asked if it talked Japanese. I said "It talked Japanese, but I couldn't quite understand it." (Laughter.) He was not quite satisfied with that, and asked permission to bring some Japanese friends of his from Harvard College. I said, "Certainly." He brought two young men there, and they talked through the telephone and listened; so that Japanese was the first foreign language that was spoken over the telephone. And these two Japanese gentlemen were exceptional men. I did not know who they were at the time, but years afterwards it was revealed to me. I was in Japan, in Yokohama, when the American residents in Japan were giving a banquet to the new Japanese Minister who was going to Washington, Mr. Kamura, now at the head of affairs in Japan. I was asked to attend the banquet, and instead of being introduced to Mr. Kamura he came up to me and said, "I don't require an introduction to Mr. Bell. I knew him years ago." And he turned out to be one of the Japanese students. Then I found out about the other one in a rather curious way. The Japanese Government sent to this country at the time of the Russian-Japan war Baron Kaneko. He came to Washington and gave a lecture before the National Geographical Society. I happened to be president of that society at the time. And so, when the dinner was over and the time for speaking came, Baron Kaneko said, "I knew Mr. Bell years ago," and he told his story about the use of the telephone. So those two men, the foremost men in Japan today, Baron Kaneko and Mr. Kamura, were the two men who heard the telephone in the winter of 1876-1877. (Applause.)

A few more words, and I shall have done. On February 12, 1877, I gave a lecture before the Essex Institute in Salem, Massachusetts, and the lines were connected with Boston. The speech was transmitted between Boston and Salem, and the audience generally could hear the sound of the speaker's voice, while those who came close to the telephone were able to converse with Mr. Watson in Boston. At the invitation of the Essex Institute this lecture was repeated on February 23, 1877, and admission was charged; and on this occasion a portion of the proceeds was presented to me for my lecture on the telephone. I immediately went into Boston and we had a little silver telephone made, and it is interesting now to look back upon the fact that that was made from the first money made from the telephone.

On that occasion a very interesting incident took place. A *Boston Globe* reporter had the brilliant idea that he would send a despatch to his paper in Boston by telephone, and on that occasion the first newspaper despatch ever sent by telephone was sent to Boston by the *Boston Globe*. That, I think, more than anything else, woke up the press of the world to the advantage of the telephone. That article in the *Boston Globe* was copied all over the world, and had a great influence in modifying public opinion.

On April 3, 1877, we talked perfectly freely between Boston and New York. On April 5, 1877, there was a lecture in Providence, Rhode Island, which was attended by a great many people, and speech was transmitted to Boston from Providence, and a bugler in Boston, who was well known in Providence, played, the sounds being heard all over the large hall in Providence.

On April 4, 1877, was opened the first telephone line, the first line specially built for telephonic purposes. It simply connected the office of Mr Charles Williams, Jr., in Boston, with his house. It was a short line, but it was the first of the hundreds of thousands of miles of telephonic wire that has since been laid.

New Books.

Elementary Telegraphy, by H. W. Pendry, New York, is a manual for students and was written especially to meet the requirements of the ordinary grade of the subject as published in the syllabus of the City and Guilds of London Institute. While the work is written from an English standpoint, as far as the practice of telegraphy is concerned, it contains much matter of general interest. The underlying principles of course are the same in any country, but in this instance they are set forth in a very clear manner. The American student of telegraphy will no doubt find this part of the book of special interest, as it explains many things that are not always stated very clearly in other books of like character.

The section devoted to telegraph instruments and practice will be of interest to those who care to look beyond the American shores in matters pertaining to telegraphy. It is well to know how things are done in other countries besides our own, and a study of this section will aid in broadening the mind.

A high telephone official states that TELEGRAPH AND TELEPHONE AGE is by far the most valuable paper for information and general telegraph and telephone news that reaches telephone people.

Course of Instruction in the Elements of Technical Telegraphy—III.

(*Copyrighted.*)

(Continued from page 706, November 1.)

We began in our issue for October 16 the publication of a course of instruction in technical telegraphy. The course is published for the benefit of those of our readers who desire to fit themselves for better positions in their vocation. It is elementary throughout and will be divided into chapters, following one another in logical order.

The course has received the hearty commendation of telegraph officials and experts for its scope and accuracy and its sound practicability. In each chapter examples will be given in order to illustrate the application of the rules to practical cases, and each chapter will be followed by a series of questions pertaining to the subject of the chapter, to be worked out by the student in order to review his progress.

The mathematical section, which is now running, will carry the student through fractions, decimals, proportion, elementary algebra, etc.

DECIMALS (*continued.*)

The denominator of a decimal fraction is 1 followed by as many ciphers as there are decimals

For example, to express .004 as a demical fraction, there are three decimal places, there therefore must be three ciphers after the 1 in the denominator, thus $\frac{4}{1000}$

The value of the successive decimal orders decreases tenfold from left to right and increases tenfold from right to left. Hence, the removal of a decimal figure one place to the right by removing the decimal point *decreases* its value tenfold and its removal one place to the left *increases* is value tenfold.

The value of a decimal is not changed by writing ciphers to the right of the last figure; .00100 is still $\frac{1}{10000}$.

To reduce a decimal to a common fraction:

RULE (1). *Omit the decimal point and supply the denominator, and then reduce the common fraction to its lowest terms.*

Example: Reduce .005 to a common fraction.

Supplying the denominator; $\frac{5}{1000}$.

Cancelling the common factor 5; $\frac{1}{200}$ Ans.

To reduce a common fraction to a decimal:

RULE (2). *Annex decimal ciphers to the numerator and divide by the denominator and point off as many decimal places in the quotient as there are annexed ciphers.*

Example: Reduce $\frac{8}{125}$ to a decimal:

Dividing 3000 by 125 gives 24. Three ciphers have been added to the numerator, therefor three decimal places must be pointed off, giving .024. Ans.

ADDITION OF DECIMALS.

To add decimals:

RULE (3). *Place the numbers to be added so that the decimal points will be directly under one another. Add as in whole numbers, and place the decimal point in the sum directly under the decimal points above.*

Example: Find the sum of 156, .36, 18.025, 1.005, 4, and 100.01.

Solution:

```
156.
  .36
18.025
 1.005
 4.
100.01
279.4   Ans.
```

SUBTRACTION OF DECIMALS.

To subtract decimals:

RULE (4). *Place the numbers so that the decimal points will be directly under each other. Subtract as in whole numbers and place the decimal point in the remainder directly under the decimal points above.*

Example: Subtract .234 from .3276.

Solution:

```
Minuend      .3276
Subtrahend   .234
Difference   .0936   Ans.
```

RULE (5). *When the figures in the decimal part of the subtrahend extend beyond those in the minuend, place ciphers in the minuend above them and subtract as before.*

Example: From 506.38 take 20.0004.

Solution:

```
506.3800
 20.0004
486.3796   Ans.
```

MULTIPLICATION OF DECIMALS.

To multiply decimals:

RULE (6). *Place the multiplier under the multiplicand, disregarding the position of the decimal points. Multiply as in whole numbers, and in the product point off as many decimal places as there are decimal places in both multiplier and multiplicand, prefixing ciphers if necessary.*

Example: Multiply .326 by .0003.

Solution:

```
Multiplicand   .326
Multiplier     .0003
Product        .0000978   Ans.
```

NOTE: As there are seven decimal places in the multiplicand and multiplier, four ciphers must be prefixed to the product.

DIVISION OF DECIMALS.

To divide decimals:

RULE (7). *Place the divisor to the left of the dividend and proceed as in division of whole numbers, and in the quotient point off from the left as many decimal places as the number of decimal places in the dividend exceeds those in the divisor, prefixing ciphers to the quotient if necessary.*

Digitized by Google

Example: Divide .805 by .35.
Solution:

```
.35).805(2.3
   70
  105
  105
```

NOTE: There is one more decimal place in the dividend than in the divisor, therefore there is one decimal place in the quotient.

Example: Divide .625 by 25.
Solution:

```
25).625(.025  Ans.
   50
  125
  125
```

NOTE: There are three more decimal places in the dividend than in the divisor, therefore there must be three decimal places in the quotient, and a cipher must be prefixed.

(To be continued.)

Postal Telegraph-Commercial Pacific Cable to China and Japan.*

The Pacific cable of the Postal Telegraph-Commercial cable system was completed in July, 1903, and it has been in successful operation ever since. In 1906 further sections were added, extending it to China and Japan. The total length of the system is 10,008 nautical miles.

The laying of this great length of cable was the most difficult of submarine cable enterprises ever undertaken, the route followed being unique for its lack of natural stations, traversing as it does the greatest uninhabited waste of water on the globe.

The route has six great ocean stretches of 2,276, 1,332, 2,606, 1,631, 1,264 and 899 miles. On the first, between San Francisco and Hawaii, the mean depth is 15,000 feet with a maximum of 18,438; on the second, between Hawaii and Midway Islands, the mean depth is 12,000, the maximum 18,156; on the third from Midway Islands to Guam, Ladrone Islands, the mean depth is 15,600, with a maximum of 31,614, with sudden and great fluctuations; on the fourth, from Guam to Manila, Philippine Islands, the mean depth is 13,200, the maximum 20,400; on the fifth, from Manila to Shanghai, China, the mean depth is 8,754 feet, the maximum 13,800; on the sixth, from Guam, Ladrone Islands to Yokohama, Japan, the mean depth is 11,076 and the maximum 16,464 feet.

To bring home the significance of these immense depths in cable laying it may be explained that the amount of cable in suspension necessarily varies according to the depth and rate of paying out. In 17,400 feet, with the cable laying ship steaming at eight knots (about nine miles) per hour, no less than twenty-four miles of cable are in suspension in the water. Two and one-half hours are occupied in such case by any particular point in the cable from the time of leaving the ship to touching the ocean bottom.

*From *The Postal Telegraph.*

In the vicinity of the Pacific cable, near Guam, has been found the greatest ocean depth known anywhere, namely, the "Nero Deep," so named after the United States ship "Nero," from which the sounding was taken. A depth of 5,269 fathoms, or 31,614 feet, only 66 feet less than six statute miles, was found.

As isolated cable stations, the Midway Islands and Guam have a unique interest for the public. Midway Islands are two small islands situated half way between the United States and China coasts. They are surrounded by a coral reef of about eighteen miles in circumference. The reef protects the islands from the high seas. A rift in the reef admits vessels of eighteen feet draught into a deep and safe harbor. The "Wandering Minstrel" was wrecked here in 1887. Captain Walker, his wife and crew lived for fourteen months on the islands, subsisting on fish and the eggs of sea birds until they were rescued. The islands are under the jurisdiction of the United States Navy Department.

The Midway group is composed of two islands, the larger, called Sand Island, is 1¾ miles long by ¾ of a mile wide, and its highest elevation is 43 feet. It is composed of white coral sand and except for patches of shrub and coarse grass is barren of vegetation.

The smaller, called Eastern Island, is thickly covered with shrub and coarse grass, but is not a desirable place for habitation. It is infested with flies.

The cable station is established on Sand Island. Strange to say, this sterile sand heap in the middle of the ocean yields drinkable water at from four to seven feet from the surface.

The cable colony consists of a superintendent, a medical officer, operators, engineer, carpenter, Japanese laborers and Chinese servants. There are also two women in the colony, one being the wife of the superintendent and the other the wife of an operator, together with their three children. The live stock consists of two donkeys, a cat, 150 pigeons and eleven ducks, transported from Honolulu, and 151 chickens and two cows, which were raised on the island. During the year 1910 there was produced on the island for consumption 8,362 eggs, eighty-four chickens, fifty-two ducks and 1,029 squabs and two calves.

The colony is comfortably housed in modern commodious structures of steel and cement, and there is a tennis court of cement.

These Commercial Pacific cables are of vast importance to the United States commercially, politically and strategetically. They have increased the value and efficiency of the United States Navy, and enabled the government to keep in close touch with the military and civil authorities in the Philippines and they have strengthened the bonds between the United States and its possessions in the Pacific. American commercial interests in China and Japan have been kept up more closely by this quick communication. The old world empires of Asia are now able to communicate instantaneously with the new world of America.

Report of British Postmaster-General.

The annual report of the British Postmaster-General for the year ended March 31, 1911, shows that 86,707,000 telegrams passed over the post-office wires as compared with 86,884,000 in the previous year. The total value of the telegrams was $13,866,330, an increase of $21,265 over 1909-10. On March 31, there were 11,451 post-offices open for public telegraph business as well as 2,423 offices at railway stations and other public places.

The use of high-speed automatic telegraph apparatus has been further developed during the year. The circuits between London and many of the larger provincial offices are now continuously worked with Wheatstone apparatus during the busy hours of the day. In connection with the Wheatstone apparatus on the London-Newcastle-on-Tyne and London-Edinburgh circuits, Creed instruments, printing in type, are being used. Gell keyboard perforators are extensively employed in connection with Wheatstone working, and other types are being tried. Baudot apparatus has been installed experimentally on the London-Birmingham circuit, and Murray multiplex apparatus on the London-Manchester circuit, and further trials of Undulator apparatus have been made between Bristol and Cork.

Experiments have been made with a view to the wider use of typewriters for the transcription of messages for delivery.

The main underground telegraph line between Birmingham and Bristol has been completed, as well as the extension from Leeds to Newcastle-on-Tyne. There is, therefore, now a triangle of underground lines with the corners at London, Birmingham and Bristol, with extensions from Bristol to Plymouth and Porthcurno, where submarine cables are landed; from London to Chatham; and from Birmingham to Glasgow and Edinburgh. Liverpool, Manchester, Leeds and Newcastle are served by cables connected with the main line at Warrington.

The number of foreign telegrams sent to and from the United Kingdom during the year (exclusive of certain telegrams dealt with entirely by cable companies) was 10,678,000, an increase of about 419,000 as compared with the preceding year. Quadruplex working with the Baudot type of instrument will shortly be permanently established on two of the Anglo-Netherland wires, and experimental trials in practical working with similar apparatus on a wire to Berlin are giving satisfactory results.

Wireless Telegraphy.—The number of radiotelegrams dealt with at the post-office coast stations during the year shows a satisfactory increase, the outward radiotelegrams to ships reaching a total of 5,640, as compared with 3,266 in 1909-10, and inward radiotelegrams from ships 34,161 as compared with 27,727 in 1909-10; the total increase being 8,808, or 28.4 per cent.

During a prolonged interruption of the Stornoway cable, the telegraph traffic was diverted to the wireless telegraph stations at Tobormory and Lochboisdale, and the delay and inconvenience which formerly attended the severance of the cable connection was successfully overcome. Returns of the traffic show that an average of 230 telegrams a day (the highest number in one day being 459) were transmitted by means of the wireless service with practically no delay.

Telephones.—The total number of telephone trunk line exchanges open at March 31 last was 678, compared with 643 at March 31, 1910. The capital expenditure at the same dates was £5,337,725 and £5,054,572 respectively; the number of conversations over inland trunk lines 30,100,068 and 26,566,318 respectively; the average payment per conversation 6.10d. as against 5.99d.; the gross revenue from inland calls £765,282 as compared with £662,845: and the receipts from Continental calls £24,666 and £24,135 respectively. During the year 137 post-office telephone exchanges were opened in the provinces—97 in England and Wales, 24 in Scotland and 16 in Ireland. The question of introducing a cheaper form of telephone service in sparsely populated rural districts is under consideration.

The following estimated figures show the extent to which the telephone is being used for sending messages for onward transmission as telegrams and express letters: Telegrams, 5,372,000, an increase over 1909-10 of 9.1 per cent.; express letters 196,000, an increase of 20 per cent. The number of messages sent to the post-office by telephone for onward transmission as ordinary letters decreased from 3,200 to 3,100, whilst the telegrams delivered during the year to addresses by telephone numbered 2,447,000, as against 2,154,000 in 1909-10. The number of telegrams delivered by telephone represented 3 per cent. of the total number of telegrams delivered.

Mileage of Wire.—The total mileage of post-office wires, including spare wires, on March 31, 1911, was as follows: Public telegraphs, 311,942; telephones, 660,144; private and leased wires, 267,009; total, 1,239,095. This length is apportioned as follows: Aerial, 440,815; underground, 787,553; submarine, 10,727; total, 1,239,095.

Quick Telegraphing to South America.—When the Argentine battleship "Rivadavia" was launched recently at Quincy, Mass., the telegraphic announcement was published in Buenos Ayres four minutes afterwards. This time was beaten, however, when the Argentine battleship "Moreno" was launched at Camden, N. J. On this occasion the news was known in Buenos Ayres in less than one minute afterward. The distance between New York and Buenos Ayres is approximately 7,000 miles, and is covered by submarine cable and a cable telegraph line over the Andes mountains owned by the Central and South American Telegraph Company. The average time of transmission of regular messages between New York and Buenos Ayres in only twenty-two minutes.

QUESTIONS TO BE ANSWERED.

[One of the most effective means of imparting information is to ask and answer questions, the value and power of this method being due to the fact that the information given in an answer is specific and direct. Asking questions for the student to answer for himself has proved to be an excellent means of education, as it promotes and encourages concentration of thought and investigation in order to arrive at the correct answer. There is a general demand for knowledge on the quadruplex, duplex, etc., and to aid in the acquirement of such knowledge we are extending our aid to students by asking questions on these subjects in each issue of our journal, so that students may be encouraged to study by answering them. We use as our text book Maver and Davis' "The Quadruplex," and students should have a copy of this book at hand in order to be able to give the answers. The questions are progressive and a careful reading of the book on the points under inquiry unfold the answers. This method of acquiring technical knowledge is a fascinating one.]

CHAPTER IX (*Concluded*).

Why is it necessary to reduce the tension of the spring on the No. 2 relay when the weather changes from dry to wet?

When the weather changes from wet to dry what alteration in the spring tension of the No. 2 relay will be necessary and why?

After a quadruplex has been balanced is it advisable to give the armature of the polar relay a bias?

What is the object of centering the armature of the polar relay?

What is the objection to giving a bias to the polar relay tongue?

What are the probable effects on the operation of the instrument of giving the polar relay armature a bias?

If the writing from B comes light on the polar relay does biassing the relay armature help matters any?

What steps should be taken if B comes light on the polar relay in order to remedy the trouble?

Sometimes it seems impossible to get a balance; what may be the reasons for this?

In locating the cause of such trouble how may the polar relay be tested?

How may the fingers be used in making such tests?

How is the neutral relay tested in order to ascertain its condition?

If the relay is defective, how will the trouble be manifested?

What is the effect when one portion of a coil is crossed with another portion of the same coil?

If a balance gives about twice the usual resistance, what is the trouble likely due to?

In case the current from the home battery does not reach the B station, what is the procedure to test for the trouble?

Why is a diagram of the connections helpful in a point-to-point test?

When quadruplex trouble is deep seated, what tests should be made to locate the cause of the trouble?

What precautions should be taken regarding local batteries and contact points in order to insure good working?

Dispensing With the Repeating Sounder.

BY J. P. FERRITER, DICKINSON, N. D.

In the instructions issued January 31, 1911, by the Western Union Telegraph Company, relative to the installation and operation of the Athearn quadruplex, I note the following paragraph:

"THE REPEATING SOUNDER.—Experiments indicate the possibility of being able to dispense entirely with the repeating sounder and of operating the local sounder direct from the front contact of the neutral relay. As the feasibility of doing so has not as yet been fully demonstrated, all neutral relays are now being furnished with front and back interchangeable contacts with a view to further trials in that direction."

It has long been a matter of wonder to me that the repeating sounder was not dispensed with long ago. I have demonstrated, to my own satisfaction at least, that the repeating sounder is as useless as a fifth wheel on a wagon.

I have at several different times, in an experimental way, operated a 500-mile quadruplex without a repeating sounder and I could not see that it made a particle of difference one way or the other, whether the repeating sounder was in or not. I did not, however, work it in the manner indicated in the paragraph quoted. I simply had the distant office reserve the long end and the tap on his transmitter; this gave me his signals reversed, and, by operating my sounder from the back contact points of my neutral relay, I received the signals as they were originally made.

I am at a loss to understand why this method is not adopted in preference to that of operating the local from the front contact as suggested.

A favorable point to be noted here is that when a single wire is repeatered into the common side of a quadruplex with this arrangement the short end of the battery is to the line while the single wire is idle and closed.

The Turner Monument Fund.

Several good sized contributions toward the Turner Monument Fund have been received by the treasurer since the previous published record. Mr. W. C. Brown, president of the New York Central Lines, New York, has sent his check for $10, and others who have contributed a like amount are Mr. James Merrihew, former general superintendent of the Western Union Telegraph Company, New York, and Mr. Ralph Peters, president Long Island Railroad Company, New York. Mr. Andrew Carnegie will contribute the last $500 toward the fund.

The contributions received up to date are as follows: Previously acknowledged, $1,676.99; James Merrihew, New York, $10.00; W. C. Brown, New York, $10.00; Ralph Peters, New York, $10.00. Total, $1,706.99.

Mr. C. M. Baker, division general superintendent of plant of the Postal Telegraph-Cable Company of Chicago, in renewing his subscription, writes: "TELEGRAPH AND TELEPHONE AGE like some other things we need improves with age."

The Western Union Telegraph Company and Bell Telephone Company's Exhibit at the Western Pennsylvania Exposition, Pittsburgh.

The Western Union Telegraph Company and the American Telephone & Telegraph Company made a joint exhibit at the exposition of the Western Pennsylvania Exposition Society held at Pittsburgh, Pa., August 30 to October 21, inclusive. The accompanying illustration shows clearly the plan and scope of the exhibit, which occupied a space of 840 square feet.

At each corner of the exhibit space was erected a 20-foot telegraph pole to which were attached cross-arms and wires, and the rail enclosing the space consisted of short posts to which were attached stranded

EXHIBIT OF WESTERN UNION AND AMERICAN TELEPHONE AND TELEGRAPH COMPANIES AT PITTSBURGH, PA.

messenger wires and 60-wire cables. The floor covering was of green burlap and signs were liberally displayed, as shown in the illustration.

The Western Union exhibit consisted of a standard quartette table cut for typewriters and equipped with a full set of quadruplex instruments; a standard quartette table fully equipped with duplex instruments and a standard quartette table equipped with single Morse instruments, and relics of a telegraphic character which had been gathered from different sources.

There were also on exhibition a complete set of printer instruments, stock quotation transmitters, and tickers, all in operation, relays and pole changers for the printer system, a sub-master clock connected to a secondary clock, a standard switchboard, a complete McCullough call box system with five call boxes, all necessary tools and materials for the construction of a pole line, Wheatstone bridge testing sets, single sets of automatic repeaters, etc.

Among the relics shown were an old register, a relay and a hump-back key which were installed in the telegraph office at Rushfield, Ind., fifty years ago. These were loaned by Mr. George C. Hadley, the present Western Union manager at Mumford, N. Y.

The telephone company's exhibit consisted of two latest pattern telephone booths equipped with instruments, one private branch exchange switchboard and various styles of telephone instruments used in every day practice. There was also an exhibit of different kinds of lead-protected telephone cables in sizes from 10 pairs to 400 pairs.

During the rush hours of the afternoon and evening there was stationed at each entrance a neatly uniformed telegraph messenger who was supplied with a pole-counter. It was his business to count every person entering the exhibit space, and at the close of the exposition it was found that 23,405 people had visited and examined the various systems on exhibition. Fully 50,000 people were attracted by the display.

KERITE

INSULATED WIRES and CABLES

DEPENDABLE

Kerite Cables installed upward of 35 years ago, and exposed to deteriorating influences, are giving perfect service to-day.

EFFICIENT

Kerite does not rely upon the rubber in its composition for insulating efficiency. Kerite itself is a compound having superior insulating qualities.

SERVICE

A half century of successful service has demonstrated that Kerite possesses the essential qualities of safety, reliability and economy to an exceptional degree.

Kerite Insulated Wire and Cable Co.

The Railroad.

Mr. W. F. Williams, superintendent of telegraph of the Seaboard Air Line, Portsmouth, Va., and wife, were recent New York visitors.

Mr. James Kent, manager of telegraphs, Canadian Pacific Railway, Montreal, Quebec, recently made his annual inspection trip over the company's lines in the West. He was accompanied by Mr. B. S. Jenkins, of Winnipeg, general superintendent of telegraphs, Western lines of the Canadian Pacific.

Telegraphones on the Great Western. — The Great Western Railway is installing telegraphones on its line. Each of the principal stations along the road will be equipped with the apparatus, also the passenger and freight trains.

Dispatching on the Florida East Coast Railroad. —The Florida East Coast Railroad is planning to install a complete system of Western Electric telephone train dispatching equipment including forty-eight selectors to be used in signalling way stations, four dispatcher's equipments, together with ninety-six complete way stations and siding telephones. The district to be covered by the new telephone system extends from Jacksonville to Key West, Fla.

Telegraphones on Reading Road.—The Philadelphia & Reading Railway has installed the telegraphone between Shamokin and Wagontown. Telegraphones are also being installed on the Shamokin Division between Herndon branch junction and Cabel, and on the Lebanon Valley branch between Palmyra and Landis Siding. The company also proposes to make further installations of the telegraphone. Mr. C. M. Lewis is superintendent of telegraph, Reading, Pa.

Telegraphones on Chicago Great Western.— The Chicago Great Western Railway has recently installed on its eastern division two train dispatching telephone circuits and two local message telephone circuits. On the northern, eastern and southern divisions telegraphones are being installed at important points, and on the western division all trains are being equipped. Mr. G. O. Perkins is superintendent of telegraph of the Chicago Great Western Railway, Chicago, Ill.

Train Dispatching on the Louisville & Nashville.—The Louisville & Nashville Railroad, which is now operating over 2,200 miles of circuits by telephone, recently placed an additional order with the Western Electric Company for forty-two selectors to dispatch its trains over a new line to run from Lexington to Quicksand, Ky. The new line will cover a total distance of ninety-six miles, and the dispatcher for it will be located at Lexington. A message circuit will parallel the train circuit on this line and will be equipped with the same number of stations.

Telephone Train Dispatching Equipment. — The United States Electric Company, New York, has delivered to the Chicago, Rock Island and Pacific Railway the dispatchers and station equipments for a circuit of thirty telephone train dispatching stations. The Gill selector box outfits at the several stations are of the latest improved pattern. To the Gulf, Colorado and Santa Fe Railway the United States Electric Company has delivered twelve station selector outfits for telephone train dispatching with the local bell circuit, the dispatcher's apparatus equipment having provision for an extension of the circuit to twenty-four stations.

Mr. Keenan's New Duties. — Mr. Edwin C. Keenan, superintendent of telegraph of the Lake Shore and Michigan Southern Railway, Cleveland, Ohio, has been appointed jointly by Mr. W. W. Ryder, general superintendent of telegraph of railway companies, New York Central Lines, Chicago, and Mr. T. P. Cook, general superintendent Western Union Telegraph Company, Chicago, superintendent of telegraph, of the Lake Erie & Western, and Ft. Wayne, Cincinnati & Louisville Railroads, and the Northern Ohio Railway, with office at Cleveland, and will jointly represent these companies and the Western Union Telegraph Company. Mr. Keenan has also been appointed superintendent of telegraph of the Toledo & Ohio Central and Zanesville & Western Railways, with office at Cleveland, and will also jointly represent these companies and the Western Union Telegraph Company.

Telephone Train Dispatching on the "Katy."— Mr. W. H. Hall, superintendent of telegraph of the Missouri, Kansas & Texas System, has completed the construction of two telephone train dispatching circuits which have been in operation since October 1. On the Chattaw division the McAlester dispatcher handles the double track main line from McAlester, ninety-five miles south to Denison, Tex., with a part of the Oklahoma City line from Atoka on the main line, west to Coalgate, Okla. Way stations located at frequent intervals along the line are connected with the telephone circuit and on the single track sections the blind passing tracks are provided with booth telephones. The way station equipment consists of Gill selectors of the two-figure main-line bell type, together with the standard accessory apparatus. The Waco division circuit extends from Smithville, Tex., the dispatcher's office, 158 miles north to Hillsboro and includes forty-seven miles of the San Antonio line from the junction at Granger west to Austin. Thirty-four way telephone stations and nearly as many booth telephones are installed on the circuit.

The Late Isaac T. Dyer.

In the death of Isaac T. Dyer, superintendent of telegraph of the San Pedro, Los Angeles and Salt Lake City Railroad, at Los Angeles, Cal., October 25, the railway and commercial telegraph fraternity loses a member who was beloved by all who knew him. His nature was as gentle and sympathetic as a woman's, and he found much

Digitized by Google

happiness in doing good to others—he did not live for self alone. His was a most lovable character and many of his associates have real cause to grieve over his death, which occurred in the prime of his career of usefulness. He was particularly endeared to his fellow-members of the Association of Railway Telegraph Superintendents, and they all without exception feel in his death the loss of a personal friend. The memory of Isaac T. Dyer will long live in the minds of those who were fortunate enough to come into contact with his kindly personality.

Meeting of Eastern and Western Divisions of Association of Railway Telegraph Superintendents.

Final arrangements have been made for the holding of a joint meeting of the Eastern and Western divisions of the Association of Railway Telegraph Superintendents in the General Office Assembly Room, Chicago and Northwestern Railway, Chicago, Ill., November 23 and 24.

The meeting will be called to order at ten o'clock a. m. November 23 and the following matters will be discussed and acted upon: Election of officers for the two divisions; handling Western Union reports and other similar business between railroad offices and the superintendent of telegraph by railway mail. This practice has recently been objected to by the Post Office Department and an expression from all members as to their instructions is solicited.

Information will be requested of such members as are prepared to furnish it on the following matters:

1. Number of maintainers or inspectors for a telephone train dispatching circuit or additional telephone message circuit or circuits; telephone mileage; frequency of train service and number of stations with and without selectors on each circuit.

2. Rate of pay for such maintainers or inspectors.

3. Expenses if allowed, and whether limited or unlimited.

4. Statistics as to the economy or saving in train operation or acceleration of train movement since the adoption of the telephone.

5. Retention in files of all telegrams as per order of the Interstate Commerce Commission, dated June 8, 1911, and what plans have been worked out for relieving the files of these cumbersome telegrams.

An invitation has been tendered and accepted to visit the plant of the Kellogg Switchboard and Supply Company, and transportation will be provided. Three o'clock p. m. November 23 has been fixed as the time and date for this visit instead of the date previously announced.

On November 24, after the morning session, the members will visit the Hawthorne plant of the Western Electric Company, where luncheon will be served, after which a trip through the works will be made. All members are earnestly requested to attend this joint meeting and to come prepared to discuss the subjects introduced.

Mr. Charles Selden, superintendent of telegraph, Baltimore & Ohio Railroad, Baltimore, Md., is chairman of the Eastern Division, and Mr. E. A. Chenery, superintendent of telegraph, Missouri Pacific Railway, St. Louis, Mo., is chairman of the Western Division.

Our Subscription Contest.

In our issue for September 1 we announced the opening of a subscription contest, offering five prizes amounting to $100 to those of our regularly appointed agents who sent in the largest number of new subscriptions during September, October and November and up to December 21. The prizes are as follows: First, $50; second, $25; third, $15, and the fourth and fifth, $5 each. The contest is limited to new subscriptions and renewals only. The total amount received from each agent on this account will decide the contest and in the event of a tie on any one prize, the prize will be divided.

This is an excellent chance for agents to earn a substantial amount of money not only by capturing a prize, but also from the usual commissions earned from the subscriptions sent in.

The contest is urged in the interests of our circulation, which we think ought to be very largely increased. Money must accompany all orders for subscriptions. Many of our agents secure subscriptions or renewals for from two to ten years. In cases like this a five or ten years' subscription will count as five or ten yearly subscribers, as the case may be.

Those at points where we have no agents will find it to their advantage to secure an agency appointment to canvass their section and participate in this contest. Many subscribers can be secured in this way, and the active canvasser in a small town will find as great an opportunity to win a prize as will a regular agent in a large city. It must be remembered that all operators are not in the cities. Many permanent agencies can thus be established to the present and future advantage of those participating in the contest.

Our agents are showing great activity in the contest and new subscriptions are coming in in a satisfactory manner, but we desire a great many more before the contest closes. Every man in the telegraph business should be a subscriber, and there is a large field yet to be developed by our agents. Each one will find in his own territory many persons who are not subscribers, although they may be readers of occasional copies of TELEGRAPH AND TELEPHONE AGE. These should be singled out and argued with systematically and with judicious persistence. The strongest argument an agent can present to prospects is that the paper is educational and contains news and information that are worth many times the subscription price. Our instruction course in the elements of technical telegraphy, which began in the issue for October 16, is a technical education in itself, and could not be obtained for $25.00 elsewhere, yet this is given free to our subscribers.

Keep at it! If you do not capture your man today, try him to-morrow; he may be in a more receptive mood then; but keep at it.

Telephonology

The New Telephone Book

Contains 16 chapters covering every branch of telephony.
Comprises 586 pages full of valuable information for every one interested in the telephone.
Has 700 illustrations of up-to-date apparatus and circuits.
Written for the practical telephone man, who has no time to study theory, but who is looking for practical instruction "how to do" things.
Tells how to locate and remedy trouble, line, instrument and switchboard.
How to make simple testing equipment and to use it.
All modern systems—both Magneto and Common Battery described and illustrated.
The whole subject is thoroughly covered, from the theory of magnetism to automatic and wireless telephony, including composite, harmonic and selective lockout systems.

Obituary.

Daniel F. Drawbaugh, who gained much notoriety several years ago through his claims as being the original inventor of the telephone, died at his home near Harrisburg, Pa., on November 3, at the age of 84 years. Mr. Drawbaugh was an inventor of considerable note.

Hiram Morse, aged 72, an old-time telegrapher, died in Detroit, Mich., October 22. He was employed on the Grand Trunk Railway for forty-five years, being superintendent of the Detroit division between 1875 and 1880. Deceased was retired four years ago.

Hugh W. Gillespie, aged 52 years, a well-known Boston operator, died at Winthrop, Mass., on November 1. He entered the service in 1873. Mr. Gillespie was a member of the Old Time Telegraphers' and Historical Association and several telegraph benevolent organizations.

J. T. Bivens, a former telegrapher and newspaper man of Washington, D. C., died in that city October 31. He entered the Confederate Army at the age of 14 years, and five years after the war entered the Signal Corps of the United States Army, serving as a telegrapher for a number of years.

ANSWERS TO QUESTIONS.

[In this department questions on matters of a practical character, and of general interest, will be answered. Questions intended for this department must be signed by the writer's full name—not for publication, but for identity. No attention will be paid to anonymous communications.]

(71) Q. Does the core of an electromagnet become fully magnetized the moment the current is turned on? K.

A. No; it requires time to magnetize a magnet core. This is partly due to self-induction in the magnet coils and partly to transient reverse eddy currents. The electromagnets of large generators often require ten minutes or more to "build up" their magnetization.

(72) Q. Is it true that Emperor Napoleon III. invented an electric battery? Please describe the battery. J. J. K.

A. Yes, it is true, but we are not aware that the battery was ever put into practical use. Both plates of the battery were of copper, one being immersed in dilute sulphuric acid and the other in cyanide of potassium, the liquids being separated by a porous cell.

(73) Q. What size wire is generally used for interior wiring of telephones? W. S.

A. No. 16 or No. 18 B. & S. gauge copper wire. In dry places weatherproofing office wire should be used and rubber-covered wire in damp places.

(74) Q. What is the meaning of the letters "E. B. B." used in connection with iron telegraph wire? R.

A. The letters stand for "Extra Best Best," which means that the wire so graded is of the highest conductivity, and is the most uniform in quantity, besides being tough and pliable.

(75) Q. What is the resistance of one mile of pure aluminum wire of No. 8 gauge? J. M.

A. 5.35 ohms.

Miscellanea.

Modern China.—The telegraph operators in China have gone on strike. With striking soldiers and striking operators the Chinese Government is having troubles of its own.

Teaching of the Sciences in the Schools.—Dr. Harvey W. Wiley, chief of the chemistry bureau of the Department of Agriculture, Washington, D. C., does not advocate teaching children the sciences in the public schools. They ought to be taught the dignity of labor, he says, and that the breaking of a promise is wrong.

Monopoly Charged.—A despatch from Washington states that petitions have been filed with the Inter-State Commerce Commission calling its attention to the "apparent purpose of the American Telephone and Telegraph Company to monopolize all wire facilities for wire communication to the destruction of competition and the possibility of low charges for the use of telegraph service."

Cincinnati Western Union Blue Book.—"The Seventh District Blue Book" is the title of a typewritten magazine gotten up in the office of the Western Union Telegraph Company at Cincinnati, Ohio. Its mission is to disseminate news and information between the officials and employes. It is well executed and full of interesting reading matter, a portrait of district commercial superintendent I. N. Miller adoring its pages.

Ruling Against Charging for Date on Telegrams.—The Public Service Commission, Second District, New York, has decided that a charge made by the Western Union Telegraph Company to the Postal Telegraph-Cable Company for the words constituting the originating address and date upon a telegram transferred by the latter to the former company is unjust, unreasonable and unduly discriminatory, and the Western Union is required to desist from the practice.

Electric Club of New England.—At a meeting of the Electric Club of New England held in Boston November 10, it was voted to affiliate with the New England Telephone and Telegraph Society as an independent unit, to be called the Western Union Chapter. A committee was appointed to carry the arrangement into effect. Mr. C. F. Ames, district commercial superintendent, Boston, and Mr. O. A. Conner, manager of the Boston district, Western Union Telegraph Company, addressed the meeting.

Electrical Instruments and Testing.

Every one connected with the telegraph and telephone service should know how to test lines and also be familiar with the instruments used in such work. It does not require much study to learn the mechanical operations of this important branch of the service, but of course a knowledge of electrical and mechanical principles involved in the design and construction of the instruments, and of the principles involved in measurements is the source of deep and never-ending pleasure to the ambitious student.

An excellent book on this subject, intended for the practical man, is "Electrical Instruments and Testing," by Norman H. Schneider, with new chapters on testing wires and cables and locating faults, written by Jesse Hargrave, division superintendent of the Postal Telegraph-Cable Company, Atlanta, Ga.

This work tells how to use the voltmeter, ohmmeter, ammeter, potentiometer, galvanometer, the Wheatstone bridge and standard portable sets. The apparatus described is modern and in universal use, and the tests are such as are required daily.

Mr. Hargrave carries the student step by step through the different methods of testing for faults, insulation and conductivity, cable faults, etc., and the simplest language possible is used. The formulas given are explained in the text preceding them, and examples are worked out in simple arithmetic.

This is one of the most practical and useful books on electrical testing instruments and testing that has been published and is fully illustrated with views and diagrams of instruments used in this line of work. Every one who desires to widen his knowledge on electrical matters should have a copy of this book in his library. Even if he never has the opportunity to make an actual test he will learn a great deal from the work that will improve his mind and general knowledge of things electric.

The price of this book is $1.00 and copies can be had of TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York. Any other book on telegraph, telephone or general electrical subjects can be obtained at the same place.

Baseball and the Telegraph.—During the three days on which the world championship baseball games were played in New York 700,000 words of press matter were transmitted by the Western Union Telegraph Company, and the total for the six games at New York and Philadelphia was 1,250,000 words. These figures far exceed the press matter that is sent from presidential conventions.

Jubilee of Opening of First Overland Telegraph Line.—On October 25, 1861, fifty years ago, the Overland California Telegraph lines were completed, and the mayor of San Francisco sent a congratulatory telegram to the mayor of New York.

Our Instruction Course in Technical Telegraphy.

We are receiving many letters of commendation regarding the instruction course in technical telegraphy now appearing serially in our columns, and all, without exception, express the belief that much benefit will result from a study thereof, not only to the individual student but to the employing companies.

Students, however, should bear in mind that there is no royal road to learning; it requires diligent study and close application to the work to acquire knowledge, and one or two readings will not bring the results. Every sentence of the lessons should be gone over and over again in order to gain a thorough understanding of the subject; knowledge cannot be gained any other way. Yet nothing is easier when the student goes to work with determination to win, and as he progresses he will find much pleasure in overcoming what seem to be obstacles.

The telegraph officials, without exception, are hearty endorsers of the course. Mr. George D. Perry, general manager of the Great North Western Telegraph Company of Canada, Toronto, Ont., states that his company has taken the matter up, as it has many other articles of special interest which appear from time to time in our columns.

The English, German, Japanese and other foreign governments also give particular attention to the special articles which appear in TELEGRAPH AND TELEPHONE AGE, and they regard the paper as having a particularly high educational value.

Every telegrapher should avail himself of this splendid opportunity to learn the technical side of his business and thus fit himself for better positions.

INDUSTRIAL NEWS.

Electric Storage Battery Convention.—The Electric Storage Battery Company, Philadelphia, Pa., held the sixth convention of its staff and sales department at the Bellevue-Stratford, Philadelphia, on November 6, 7, 8, 9 and 10. The convention was attended by the managers and salesmen from its various sales offices in Philadelphia, New York, Chicago, Boston, Cleveland, St. Louis, Denver, Detroit, Atlanta and San Francisco. At the conclusion of the convention a company banquet was held at the Radnor Hunt Club.

A Seasonable Booklet.—The Okonite Company, 253 Broadway, New York, has published an attractive booklet entitled "Economy in Joint Making, With Instructions." It contains information which should be very much in demand at this season of the year as now is the time to make repairs in the way of insulating and protecting joints so that short circuits, with their accompanying troubles, may be avoided during the winter to come. Copies of the booklet can be secured on application to The Okonite Company.

Digitized by Google

The Pittsburgh, Shawmut & Northern To Use Telephones.—The Pittsburgh, Shawmut and Northern Railroad Company has placed an order with the Western Electric Company for equipment to be used in connection with the introduction of train dispatching by telephone on a part of its system. A switchboard is also to be furnished, thus giving the railroad its own telephone system. There will be six selector stations on the dispatching circuit, which is to be approximately fifty miles in length and will extend from St. Mary's, Pa., to Brookville, Pa. The telephone stations will, for the present, be ten in number.

New York Telegraphers' Aid Society. — The annual entertainment of the New York Telegraphers' Aid Society for the benefit of the Relief Fund will take place on Tuesday evening, November 21, at the Lexington Ave. Opera House, Fifty-eighth Street near Third Ave., New York. Mr. James P. Clolery is chairman and announces that the members of the various committees are making every effort to bring this year's event up to the standard and if possible surpass previous entertainments. An interesting programme of entertainment is being prepared and a very enjoyable time is assured.

LETTERS FROM OUR AGENTS.

PHILADELPHIA POSTAL.

President Clarence H. Mackay recently visited the Philadelphia main office and spent several hours meeting the different members of the force. He seemed much pleased with the appearance of the office and had a good word for the "men behind the guns," as he expressed it.

Night wire chief J. E. Zecher and city foreman E. W. Batchelor, are again on duty after having been on the sick list for several weeks.

Mr. Charles S. Almes has been appointed repeater chief.

Mr. F. N. Wagner has been acting manager of the *Evening Bulletin* staff in the absence of T. R. Poppert.

Miss Alice D. Deasy has resigned to remove to Colorado.

Mr. Dennis A. Coyle was recently presented with twins, a boy and a girl.

Miss May Whalen has been appointed night telephone clerk.

Chief operator E. W. Miller and Messrs. Madden, Lane, Price and McCusker, of the Philadelphia office, and Conly, of the Trenton office, handled the press file of the Harvard-Princeton and the Dartmouth-Princeton football games at Princeton, N. J., on November 4 and November 11.

The great telegraphic song hit,
"SEND ME A NIGHT LETTER, DEARIE."
Good, catchy music; beautiful title design magnificently printed in colors. Title contains night letter. Sung all over New York, 17c. by mail. All popular music sent by mail.
B. L. BRANNAN,
195 B'way, N. Y.

Messrs. Denniston and Auerbach, of the Philadelphia office, very creditably handled the big file of press matter at Burlington, N. J., on the occasion of a Democratic rally at that place on November 4.

Additional sets of low-resistance quadruplexes are being installed here to meet the increasing demand for better facilities.

The Telegraphers' Mutual Benefit Association, 195 Broadway, New York, combines fraternalism with sound business principles; it offers to the telegraph and telephone employe an absolutely safe form of protection, at a cost within the reach of all and lower than can be found elsewhere. Membership is open to employes in commercial or railroad telegraph or telephone service, and it is manifestly to the interest of those who are eligible and wish to secure life insurance within their means, to secure without delay a certificate for $1,000 or $500, or both, at rates based on present age.

Rare Books For Sale. — Transactions of the American Institute of Electrical Engineers, Vols. 1 to 27, 1884 to 1908, monthly numbers, unbound, in excellent condition. $100. Geo. C. Maynard, U. S. National Museum, Washington, D. C.

OFFICE MANAGEMENT
Report writing—handling of telegraph office accounts—relation of the operator to the public—penmanship—Lectures and practical work.
A new course designed to prepare telegraph operators for advancement—a thorough course by leading experts.
Booklet "H" to any address.
EAST SIDE Y. M. C. A. TELEGRAPH SCHOOL
New York City

An Interesting Letter.—Mr. A. L. Suesman, of Oak Bluffs, Mass., has facsimiles of an interesting letter from General Thomas T. Eckert to Fred Catlin. A copy may be obtained by sending four cents in stamps to Mr. Suesman.

Martin's double or single lever **VIBROPLEX** $7.50. D. C. DeLany, 15 S. Broad St., Atlanta, Ga.

TRANSMITTING MACHINES
I am placing on the market improved YETMAN TRANSMITTING TYPEWRITERS, and KEYBOARD TRANSMITTERS without typewriting features. Am prepared to exchange, repair or rebuild all old machines. Write for catalogues and particulars to
James Uncles, NORTH ADAMS Massachusetts

Rubber Telegraph Key Knobs.

No operator who has had to use a hard key knob continuously should fail to possess one of these flexible rubber key caps, which fits snugly over the hard rubber key knob, forming an air cushion. They render the touch smooth and the manipulation of the key much easier. Price, fifteen cents.

J. B. Taltavall, TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

SOME POINTS ON ELECTRICITY.

BY WILLIS H. JONES.

Fuses and Lightning Arresters.

No doubt the majority of persons who have occasion to renew or replace fuses and arresters, possess a fair knowledge of the construction, capacity and general use of these devices, but there are always others who simply consider a fuse a fuse, and an arrester an arrester, to be used indiscriminately wherever one or the other is required. Happily we may disregard the latter class, as any one possessing so limited a knowledge does not usually hold a position of much importance. Yet there are certain facts in connection with fuses and apparatus that even some fairly informed attendants have never had their attention called to, and which should be of great value to one located at a point somewhat distant from the supply department, or where he may be called upon in an emergency to personally make repairs.

For example, let us take an arrester of the cartridge type, which in addition to the fuse alloy within the cartridge, has, as a lightning arrester proper, two small carbon blocks insulated from one another by a thin sheet of mica. Let us now suppose that the mica strip has become damaged by a heavy stroke of lightning and the attendant not possessing another attempts to repair it. It seems like a very simple operation—merely that of obtaining another strip of mica, cutting it to the right length and width, and placing it between the two carbons—but that is not all that is required. You should know exactly how thick the sheet should be, otherwise you do not know whether you have a protector or not. This is a detail one learns only from the specification papers regulating its construction, or by information obtained by the commendable habit of asking questions. For instance, the mica sheet, as also in case of fuse alloy, to be of any practical value must have a known breakdown capacity. For mica the capacity is given in volts; for fuses in amperes.

Referring to the subject of repairs, suppose the damaged sheet of mica was .011 of an inch in thickness. We know from data obtained by many tests that it has a "break-down" capacity of approximately 750 volts. Now suppose the attendant, not appreciating the importance of this, had placed a store-purchased sheet of double that thickness between the carbons. What would be the result of his well meant efforts? Simply this: He would have endangered perhaps very delicate and costly apparatus because the mica would not break down, and thus protect, when a potential of 750 volts occurred. He might just as well have had no arrester at all in the circuit, for the reason that its breakdown capacity is entirely too great for the purpose for which it was intended, so it is best to always get an exact duplicate, as to dimensions and consistency, of any part you wish to replace or repair.

It might be asked, "What is the necessity for both fuse and carbon-mica in the arrester?" "Wouldn't the fuse melt also?"

No, or at least not always, for the reason that a certain length of time is required for heat to develop, as well as for the constituents of the alloy to separate and break the wire.

On the other hand, a high e. m. f., such as that of a stroke of lightning, pierces the mica instantaneously, and thus diverts the greater portion of the current into the ground before it reaches the fuse alloy.

The "breakdown" capacity of mica in sheet form of different thicknesses should make not only an interesting, but a valuable subject for study, as mica is now fast superseding hard rubber for insulating purposes wherever possible. All new standard telegraph apparatus, such as keys, transmitters, repeating sounders, etc., have mica insulation. It will not melt and cannot be destroyed by such powerful currents that prove fatal to the life of hard rubber.

In like manner there are a few things concerning fuses that are often overlooked by unobserving persons if not actually unknown.

Digitized by Google

Take, for example, the 3/10 and 8/10-ampere standard coil type fuses used in the porcelain block receptacles. They both look practically alike as to size, construction and general appearance when not inspected closely. Hence if an 8.10 fuse should be mistaken for a 3/10 fuse and used as a substitute therefor, it would be no protection at all, as the danger mark could be reached and passed long before a blow-out would occur. The similarity in the appearances of the two fuses is due to the fact that the coil surrounding the alloy or core of each type consists of practically the same size insulated wire.

No doubt there are also those who are under the impression that the coil wire itself constitutes the fuse proper. Such, however, is not the case. The short length of lead wire with which the coil wire is connected in series is the active part of the fuse, and by its dimensions, or diameter, one should readily be able to distinguish a 3/10 from an 8/10 fuse, even though no other information were available.

Again a 3/10 fuse possesses about four ohms resistance which must be taken into consideration. For instance, if placed in series with a four-ohm sounder circuit fed by a two-volt storage battery, the total resistance would be eight ohms and the volume of current would be just right, viz.: 250 milliamperes. But, should you substitute an 8/10-fuse, which has practically a negligible resistance, the sounder would receive 500 milliamperes, which is entirely too much.

Even in the case of straight bare fuse wire, one cannot be too particular in choosing a substitute link when a blowout occurs. The same diameter of fuse-wire by different manufacturers may vary considerably in capacity and resistance per given length.

The lesson to be learned is that substitutes of all kinds should be identical in every respect with the material discarded.

Repeater Cords.

Referring to the article of Mr. Willis H. Jones, on page 663 of our October 16 issue, and page 695 of the November 1 issue, on the subject of loop, cord, wedge and jack troubles, Mr. H. C. Pierce, wire chief of the Omaha, Neb., Western Union office, writes:

"In this article is the statement that neither the old nor the new repeater cords will answer the purpose of cutting together the old and new type of multiplex sets.

"I would like to say that we have in service both old and new style in the office here and cut them together with the old style cord by leaving the battery on the new set the same as if we were to work it on a jumper. Cut it through to the old set with the old cord in the ordinary way and throw the three-point battery switch of the old set to the grounded side as is done with one set when two of the old style sets are cut together. This saves any changes in wiring of any kind."

Recent Telegraph and Telephone Patents.

Personal.

Mr. Thomas D. Lockwood, general patent counsel of the American Telephone and Telegraph Company, Boston, Mass., is spending a few weeks at Old Point Comfort, Va.

Mr. W. H. Sawyer, a former official of the Phillips Electrical Works, Providence, R. I., a well-known old-time telegrapher, but now retired, has gone to Pasadena, Cal., to spend the winter.

Mr. A. L. Edgecomb, superintendent of telegraphs of the Northern Telegraph Company, Boston, Mass., is taking a long rest in the Maine woods in search of health. At last reports he was steadily improving. Mr. Edgecomb was formerly superintendent of the Postal Telegraph Cable Company at Boston.

Mr. C. E. Davies, manager of the Great North Western Telegraph Company's office at Ottawa, Ont., has been appointed supervisor of equipment

Digitized by Google

of the larger offices of the company in addition to his regular duties as manager. His headquarters will remain at Ottawa.

Mr. W. B. Scott, vice-president and general manager of the Union Pacific Railway, with office at Omaha, Neb., began his business career as a messenger on the Grand Trunk Railway at Guelph, Ont., afterwards becoming an operator at Toronto for the same road. Later he became superintendent of telegraph on the Chicago Great Western. He has filled many important railroad positions.

Mr. Donald Murray, of London, Eng., the inventor of the Murray printing telegraph systems, is in New York exhibiting his apparatus. Ten years ago Mr. Murray was identified with the Postal Telegraph-Cable Company in this city since then he has been developing and installing his systems in England, Germany, Russia and other countries. Mr. Murray expects to be in New York several weeks.

Postal Telegraph-Cable Company.

EXECUTIVE OFFICES.

Mr. C. H. Mackay, president, is in the South on a combined business and pleasure trip.

Mr. E. J. Nally, vice-president and general manager, has returned from his extended trip of inspection to the Pacific coast.

Mr. T. N. Powers, chief operator of the Chicago office, spent several days recently in New York on business connected with the service.

Mr. Adolf Franke, director of the Siemen's and Halske A. G., Berlin, Germany, who is in this country on a visit of inspection of electrical plants and industries, visited the operating room and other engineering departments of this company on November 20.

Mr. H. H. Hall, manager of the Postal Telegraph-Cable Company, Ashtabula, Ohio, and a prominent citizen of that place, celebrated his seventy-fifth birthday on November 3. He entertained five other gentlemen whose ages ranged from 75 to 85 years.

Mr. H. L. Carpenter, manager at Asbury Park, N. J., is spending Thanksgiving with his mother at Schenectady, N. Y.

Miss E. G. Trice, manager at Seaford, Del., spent November 23 in New York visiting branch offices and sight-seeing.

John J. Kennedy, aged 54 years, marine operator for this company at New York, died on November 19. Deceased was identified with the telegraph department of the Maritime Exchange for over 20 years, prior to his employment by this company. He was an authority on marine matters.

Mr. George R. Andrews, former manager of this company's office at Fresno, Cal., is now public administrator at that place.

Among the recent executive office visitors were: N. C. Pangburn, foreman of construction, and W. M. Pruyn, manager, Albany, N. Y.; C. A. Richardson, superintendent, and J. D. McDonald, chief operator, Boston, Mass.; H. D. Reynolds, district superintendent, and L. J. Reynolds, assistant manager, Buffalo, N. Y.; C. E. Diehl, manager, Harrisburg, Pa.; R. P. Martin, manager, Hartford, Conn.; C. H. Hellmuth, manager, Hoboken, N. J.; R. A. Barton, manager, Lancaster, Pa.; N. C. Hall, manager, New Haven, Conn.; J. F. Coogan, manager, Newark, N. J.; C. E. Bagley, superintendent, A. E. Zintl, assistant manager, and E. W. Miller, chief operator, Philadelphia, Pa.; H. Scrivens, superintendent, and T. Peckes, district foreman, Pittsburgh, Pa.; G. S. Richtmyer, manager, Passaic, N. J.; G. H. Mills, manager, Providence, R. I.; S. G. Fitch, manager, Scranton, Pa.; S. W. Smith, manager, Saratoga, N. Y.; G. M. Foote, manager, Washington, D. C.

This company has completed the laying of a large cable across the Mississippi river between Baton Rouge and Anchorage, La. It is 4,000 feet long and heavily armored and will form part of the New Orleans-Houston line.

This company issued an attractive slip for distribution prior to Thanksgiving. It showed the company's sign-message addressed to "Everybody, Everywhere," with an invitation to use the Postal lines in sending Thanksgiving greetings. The border of the slip was printed in colors and a colored picture showed a typical Thanksgiving scene.

The Mackay Telegraph and Cable Company opened its Beaumont, Tex., office on November 16. Mr. W. H. Pippitt is the manager.

The office of the Mackay Telegraph and Cable Company in San Antonio, Tex., is being fitted up in anticipation of the completion of the building of the lines to that point. It is expected that they will reach that city about December 1. Mr. A. G. McGalin is the electrical engineer in charge of the work.

Western Union Telegraph Company.

EXECUTIVE OFFICES.

Messrs. G. M. Yorke, engineer; E. Y. Gallaher, auditor; Robt. E. Chetwood, engineer of construction and W. N. Fashbaugh, traffic engineer, have returned from a trip to Chicago on company business. Mr. Belvidere Brooks, general manager, who accompanied the party from New York, stopped over for a few days' rest at French Lick, Ind.

Mr. T. W. Carroll, assistant to the general manager, has returned from his trip through the South.

Mr. R. W. Whitehead, division plant superintendent, and Mr. E. Lamont, equipment supervisor, Chicago, Ill., recently spent a few days in New York on company business

Mr. J. Cahill has been appointed general traffic chief at the New York Cotton Exchange. Mr. Cahill was formerly manager.

Digitized by Google

Mr. J. Veitch has been transferred from 16 Broad Street to the Cotton Exchange district as district commercial manager.

The following appointments of managers have been made in New York City: Mr. M. Posner at 32 Desbrosses Street, vice J. A. Reynolds transferred to the general operating department. Mr. J. J. Gilroy at 693 Columbus Avenue, vice N. Feder transferred to the general operating department and W. A. Sanford at 426 Columbus Avenue vice J. J. Gilroy.

A special meeting of the Commercial Managers Association of New York was held November 17 for the purpose of making arrangements for the fall dinner, which will be held in the first week in December. All of the commercial managers of New York City were present. Mr. A. W. McMahon, district commercial manager, read a paper on "Salesmanship."

Plans are being prepared for the erection of a twenty-six story modern building on the site of the present structure at 195 Broadway, New York, to cost $3,000,000. The rear end of the building, with a frontage of seventy-five feet on Dey Street, below the present structure will be erected first and ultimately the building will be extended to take in the corner at Broadway and Dey Street. It is stated that the first work will be started May 1, 1912.

Mr. J. W. Ware, of the Birmingham, Ala., Western Union office, has been appointed chief clerk to division commercial superintendent J. M. Stephens, at Atlanta, Ga.

Mr. H. C. Baker, night chief operator of the Knoxville, Tenn., office has been promoted to be chief operator vice A. J. Storey, resigned.

Mr. George R. Shultz, manager of the Western Union Telegraph office and cables landing at Punta Rassa, Fla., was a recent New York visitor. He is on a leave of absence of several weeks, and will visit Chicago, Atlanta, Ga., and other places before he returns home. Mr. Shultz went to Punta Rassa in 1866 and is a prominent citizen of that place. He is proprietor of a fine large and popular hotel on the beach at that point.

Mr. Richard Terhune manager for the Western Union Telegraph Company at Ossining, N. Y., has been retired from further active duties after a service of fifty-two years. He is now seventy-two years old, and established the office in Ossining in 1864.

Several improvements have been made in the Cleveland, Ohio, main office, to facilitate the handling of the growing business and provide greater comfort for the employes. The old lighting arrangement has been replaced by more modern equipment and commodious quarters have been provided for the clerical force.

The office of this company at Tacoma, Wash., has been remodeled and is now modern in every way. New equipment has been installed in the operating and telephone rooms, and the messengers have comfortable and commodious quarters. Mr. R. R. Sprinkle is manager of the office.

Mr. Vail in California.

Mr. Theo. N. Vail, president of the American Telephone and Telegraph Company and the Western Union Telegraph Company, was in Los Angeles, Cal., recently. In an interview Mr. Vail gave his views with reference to the telephone situation in that city. Among other things he stated that the American Telephone and Telegraph Company is conducting elaborate experiments in wireless telephony. He stated that the telephone line between Los Angeles and New York would probably be ready by November 1, 1912. It will cost $500,000 for line alone, and the cost per conversation will probably be between $14 and $15.

Boston Western Union Conference.

The second annual conference of the heads of the commercial department of the Western Union Telegraph Company in and around Boston, was held in that city November 22. A business meeting was held in the afternoon and in the evening a banquet which was presided over by Mr. O. A. Conner, manager of the Boston office. The attendance was about 100.

Mr. E. M. Mulford, division commercial superintendent, New York, told of what the company had done during the past year in the matter of increasing business and giving better service. Mr. A. C. Kaufman, commercial agent, New York, discussed the question of soliciting business, while other speakers included Messrs. C. F. Ames, district commercial superintendent, L. D. Wilbourn, district traffic superintendent, and W. S. Barker, district plant superintendent, Boston.

Western Union Conference in the South.

A conference of division officials and district managers was held in Atlanta, Ga., November 21, 22 and 23 at the call of Mr. H. C. Worthen, general superintendent, Atlanta, Ga. In the evening of November 21 Mr. Worthen entertained the visiting superintendents at a dinner and reception at his home, and on the following evening Mr. J. M. Stephens, district commercial and traffic superintendent, likewise entertained the managers. On the evening of November 23 the entire party met at a banquet at the Capital City Club. Following are the names of those who were present:

Messrs. H. C. Worthen, general superintendent; J. M. Stephens, division commercial superintendent; L. H. Beck, division plant superintendent; B. P. Hancock, traffic superintendent; J. P. Edwards, special agent to the general superintendent; J. Levin and J. E. Scofield, special agents to the division commercial superintendent; E. E. Williams, district superintendent; G. W. Lloyd, commercial superintendent; W. A. Neill, district plant superintendent, all of Atlanta. J. S. Calvert, district superintendent; F. O. Nourse, commercial superintendent, and J. B. Faulkner, district plant superintendent, Richmond, Va.; J. R. Terhune, district superintendent, H. J. Carpenter, commercial superintendent, and

Digitized by Google

W. K. McClarin, district plant superintendent, Nashville, Tenn.; L. J. Maxwell, district superintendent, S. L. Burts, commercial superintendent, and J. C. Duane, district plant superintendent, Jacksonville, Fla.

A dinner was given by Mr. E. E. Williams, district superintendent, Atlanta, Ga., at the Capital City Club, in that city, November 15, to the following managers: C. R. Hughes, Athens, Ga.; C. K. Henderson, Albany, Ga.; L. R. Daniels, Augusta, Ga.; W. W. Murphy, Savannah, Ga.; R. K. Munn, Columbus, Ga.; Frank Woodruff, Rome, Ga.; W. P. Rivers, Brunswick, Ga.; F. B. Washington, Macon, Ga., and W. J. Francis, Atlanta, Ga.

Addresses were made by Mr. H. C. Worthen, general superintendent, and division commercial superintendent J. M. Stephens. Talks were also made by J. P. Edwards and B. P. Hancock, traffic inspectors. After luncheon the managers repaired to Superintendent Williams' office, where instructive talks were given by special agents J. Levin and J. E. Schofield, after which superintendent Williams closed the meeting with an enthusiastic speech.

A conference of the managers of the larger Western Union offices in Alabama was held in Birmingham November 17, and a dinner was tendered to them by district superintendent E. E. Williams. The following managers were present: S. G. Bentley, Mobile; C. E. Davidson, Montgomery; H. Barrett, Gadsden; R. L. Smith, Selma; G. A. Maxwell, Anniston, and G. R. Calvert, Birmingham.

The Cable.

Mr. A. Focque, director of the French Cable Company, at Paris, France, has been made a chevalier of the French Legion of Honor.

Deferred Cable Service with Australia. — The Postmaster General of Australia states that it is likely that the system of "deferred rate" cablegrams will be introduced on January 1, 1911. The special "deferred rate" will not apply to cablegrams which are written in cipher, but to the plain language messages rated at 1s. 6d. (36 cents) a word.

Municipal Electricians.

Police-Call System.—One of the largest light-signaling police-call systems in the country has been installed in Peoria, Ill., by the Gamewell Fire Alarm Telegraph Company, New York.

Telephones for Milwaukee Police and Fire Alarm. — Three hundred telephones are to be purchased for the use of the consolidated police and fire alarm system in Milwaukee, Wis.

A high telephone official states that TELEGRAPH AND TELEPHONE AGE is by far the most valuable paper for information and general telegraph and telephone news that reaches telephone people.

The Telephone.

Mr. H. J. Pettengill, president Southwestern Telegraph and Telephone Company, Dallas, Tex., was a recent New York visitor. He represented the Texas business men's association at the recent meeting of railroad men at the Waldorf-Astoria Hotel.

Uniform Telephone Accounting. — The New York Public Service Commission, Second District, has prescribed a uniform system of accounts for telephone corporations in the State of New York, which will go into effect January 1, 1912.

Damage to Telephone Cable by Squirrels. — Telephone men in Ann Arbor, Mich., complain of the damage done to telephone cables by squirrels. Recently a 200-line cable was so damaged and the injured section had to be cut out and replaced with a new portion.

The Washington-Boston Underground Telephone Line.—The Chesapeake and Potomac Telephone Company recently put into service a new and modern long-distance board in Baltimore, Md. This board will be used in connection with the Washington-Boston underground service.

Automatic Telephone Exchanges.—An automatic telephone system is nearing completion in Dallas, Tex. It comprises a main and four branch exchanges. The wire plant includes 800,000 feet of wire, almost entirely in lead-covered cable. The initial capital outlay is $1,500,000. It is stated that over 11,000 service contracts have already been signed, and it is expected that the construction work will be completed by the first of the year. At Houston, Tex., there is also being installed an automatic telephone exchange which will be ready for regular operation early in 1912.

Telephone Pioneers.

Mr. T. B. Doolittle, of Branford, Conn., and Mr. C. R. Truex of New York, have been appointed members of the executive committee of the Telephone Pioneers of America, by president Theo. N. Vail.

Secretary Henry W. Pope of the Telephone Pioneers of America has appointed Mr. P. Kerr-Higgins of Oklahoma City, Okla., and Mr. E. E. Bawsell of Atlanta, Ga., corresponding secretaries of the Telephone Pioneers of America in their respective jurisdictions. Corresponding secretaries are charged with enrolling members and advising the secretary of the deaths of members and give other information likely to be of interest. Mr. Higgins is assistant to the president of the Pioneer Telephone and Telegraph Company at Oklahoma City, and Mr. Bawsell is associated with the Southern Bell Telephone and Telegraph Company at Atlanta, Ga.

Telegraphs in Manchuria.—At the end of 1910 there were fifty-six telegraph offices in Manchuria under Chinese administration. The total length of telegraph lines was 12,290 Chinese li (1 li equals 2,115 feet).

ANSWERS TO QUESTIONS.

[In this department questions on matters of a practical character, and of general interest, will be answered. Questions intended for this department must be signed by the writer's full name—not for publication, but for identity. No attention will be paid to anonymous communications.]

(76) Q. How many telegraph cables are there now in operation between Europe and America? N. I.

A. There are seventeen. Considerable information regarding Atlantic cables was given in the reply to question No. 30 in our issue for April 1, last.

(77) Q. Are porcelain insulators used to any extent in this country for telegraph lines? T. D.

A. Very little indeed, if at all. Glass is the standard insulator material in this country. The Canadian Pacific Railway, however, is using porcelain insulators very largely. Valuable articles on insulators may be found in our issues for January 16, March 16 and July 16.

(78) Q. Can you recommend some book that contains explicit directions for wire testing, according to modern practice? N. S. T.

A. Wire testing is a very important part of the work in most telegraph offices, and every operator should be familiar with the practice. Mr. Willis H. Jones' "Pocket Edition of Diagrams and Complete Information for Telegraph Engineers and Students" contains a chapter on wire testing, and in the February 16 issue of TELEGRAPH AND TELEPHONE AGE was printed an article by the same author on "Wire Patching and Testing," which will be found very helpful. Copies of this issue and of Mr. Jones' book can be obtained at the office of this journal at 10 cents and $1.50 each, respectively.

(79) Q. I have been told that when an electric current passes through a wire the useful effects are outside of the wire—in the air—rather that in the wire itself. If this is true will you please explain why, and oblige? W. T.

A. This question opens up a very interesting field for discussion and would require more space to go into it fully than we can give it in this column. What you have been told, however, is true. The most important effects of an electric current are outside of the wire. The so-called magnetic field is entirely outside and without it no electromechanical action would be possible. The wire simply directs the current of electricity along a certain path.

(80) Q. What is the concrete definition of the standard unit of resistance? D. E. C.

A. The standard unit of resistance, the ohm, is that of a column of mercury one square millimeter (.0016 sq. in.) in cross sectional area and 106 centimeters (42.4 inches) high, at a temperature of 32° Fahr.

E. H. Binford, Superintendent, Mountain Telegraph Company.

Mr. Emil Harley Binford, whose appointment as superintendent of the Mountain Telegraph Company, Denver, Col., was announced in our issue for November 1, is a native of Iowa, having been born at Cambria, in that state, on June 14, 1871. In 1892 he began his telegraphic career as operator for the Keokuk and Western Railroad at Humeston, Iowa, and was later connected with the Union Pacific Railroad. In 1898 he went with the Victor American Fuel Company as chief in the auditing department, which position he held at the time of his recent appointment as superintendent of the Mountain Telegraph Company.

Bankruptcy Against C. C. Wilson.—An involuntary petition in bankruptcy has been filed in the United States District Court, New York, against Christopher C. Wilson, former president of the United Wireless Telegraph Company, who is now serving a two-year term in the Federal prison at Atlanta, Ga., for fraudulent use of the mails. The claims total $1,685,710. The petitioning creditors are trustees in bankruptcy of the United Wireless Telegraph Company and the National Surety Company of New York, and Herman G. Neuhoff.

The "Seventh District Blue Book."—The December number of the "Seventh District Blue Book," issued by the staff of the Cincinnati, Ohio, office of the Western Union Telegraph Company, is an interesting and unique production, and is worth more than a passing notice. The pages of reading matter are reproduced on a typewriter duplicator, and the cover is a blue print made from a design on tracing cloth. All the mechanical work is done by stenographers, clerks and office boy in the district commercial superintendent's office. The reading matter is of excellent variety and quality and reflects great credit upon those who are concerned in the production of this unique pamphlet.

Two-Volt Dry Cell.—A new two-volt dry cell is being placed upon the market, each cell having, it is claimed, an energy output equal to eight of the average dry cells.

New Electrical Invention by Prof. Pupin.—At the meeting of the National Academy of Sciences held in New York, November 22, Professor M. I. Pupin, of Columbia University, described an electrical apparatus which he purposes demonstrating at the Spring meeting of the Academy, by which telegraph and telephone currents can be greatly augmented.

Descriptions of inventions and latest and approved apparatus, the latest news in the telegraph and telephone fields and educational articles are the chief features of TELEGRAPH AND TELEPHONE AGE.

Fall Dinner of the Magnetic Club.

The Magnetic Club held its fall dinner at the St. Denis Hotel, New York, in the evening of November 15 and it was largely attended. It entertained as guests officers and members of the executive committee of the Old Time Telegraphers' and Historical Association and the Society of the United States Military Telegraph Corps and the out-of-town delegates to the annual meeting of the Telegrapher's Mutual Benefit Association, which was held in the afternoon of the same day.

An excellent dinner was served and much enthusiasm prevailed. During the dinner, vocal and instrumental music was given with fine effect, the singing of the Postal Glee Club being particularly well rendered.

At the conclusion of the dinner president C. P. Bruch read letters from Hon. W. S. Jordan, of Jacksonville, Fla., president of the Old Time Telegraphers' and Historical Association, Col. W. B. Wilson, of Holmesburg, Philadelphia, Col. A. B. Chandler, and others in which they expressed their regrets at not being able to attend the meeting.

After welcoming the members of the United States Military Telegraph Corps, president Bruch called upon Mr. David Homer Bates, secretary of the society, for a few remarks.

Mr. Bates referred to Mr. Andrew Carnegie's pensions to needy members of the military telegraph corps; to Mr. W. J. Dealy as being the first prisoner of the war, and to the monument to Secretary E. M. Stanton, which was recently unveiled at Steubenville, Ohio.

President Bruch then, after paying a tribute to the old time telegraphers and extending the hospitality of the club to them, introduced Mr. W. J. Dealy who spoke of his acquaintance with Professor Morse and James D. Reid. He referred to Mr. Walter P. Phillips—who was present—as a man who knew the telegraph business from A to Z.

Mr. Phillips was the next speaker. He related an ancedote of Mr. P. B. Delany and Mr. Thos. A. Edison.

Mr. S. S. Garwood, of Philadelphia, thanked the club for its hospitality of many years in inviting the delegates of the Telegraphers'Mutual Benefit Association to its dinners. In closing he proposed three cheers for president Bruch, which were given with hearty good will.

Major Samuel Reber, chief signal officer of the eastern division, United States Army, made a few remarks, and was afterward elected a member of the club by acclamation on the motion of president Bruch. Major Reber expressed his appreciation of the honor.

Remarks were also made by Mr. C. A. Tinker and Mr. W. L. Ives.

President Bruch, in closing the oratorical part of the programme, referred feelingly to the late James D. Reid, the first superintendent of telegraph and an organizer and first president of the Telegraphers' Mutual Benefit Association, whose remains now lie in the cemetery in Rochester, N. Y., marked by a very simple headstone. He suggested that the telegraph associations including the Magnetic Club, and the telegraph fraternity at large, co-operate in a movement to raise funds for the erection of a suitable monument to mark the grave, and a motiion was carried to take the matter up.

The meeting closed with a vaudeville entertainment .

Following are the names of those present:

Albany, N. Y.—N. C. Pangburn and W. M. Pruyn.

Atlantic City, N. J.—G. Scott, M.D.

Boston, Mass.—P. J. Farrell, J. D. McDonald, C. A. Richardson.

The Development of the Telephone in Pittsburgh.

Mr. F. H. Bethell, vice-president of the Central District and Printing Telegraph Company, New York, on October 27 made an address before the Pittsburgh Telephone Society, Pittsburgh, Pa. The address related principally to the industrial growth of Pittsburgh, with the development of the telephone interwoven.

Among other things Mr. Bethell said: "In passing to the development of the wire service, I am at the outset going to refer to a Pennsylvania man, and a telephone man, whose interest in the development of the telephone and the telegraph is as strong today as it was sixty years ago, when he was in the military telegraph service—Mr. Richard O'Brien, a director in the Bell Telephone Company of Pennsylvania, and for many years a director in the old Pennsylvania Telephone Company.

"In May, 1861, Mr. O'Brien, then a boy, was the military telegrapher stationed at the arsenal at Washington, D. C. One day in June, of that year, President Lincoln visited the arsenal and, going to the telegraph instrument to write a message, he watched Richard send it and take another. I am quoting now from 'Telegraph in Battle:'

> "Richard reading, of course, by sound and writing in beautiful penmanship, Mr. Lincoln remarked, 'Young man, you do that well; where do you hail from?' 'From the Pennsylvania Railroad, Mr. President,' said Richard. 'Are you one of the operators who came with Carnegie and Bates?' 'Yes, Mr. President.' 'Well, you are in a pretty safe place here, surrounded by all these big guns.' 'Yes, Mr. President: but I would much rather be at the front where I can hear them roar.' Mr. Lincoln seemed amused at this, and asked his name. Richard told him. He smiled and, turning to Major Ramsey, who was with him, said, 'He comes of a fighting race; treat him well or he will run away to the front.' It was not long until Richard was in the front and heard them roar."

"Mr. O'Brien's desire to be in the front and to 'hear them roar' is the desire of all good telephone and telegraph men."

New Book.

The Boy's Life of Edison, by W. H. Meadowcroft. This latest addition to the wonderful story of the life of Mr. Thomas A. Edison and his achievements is an intensely interesting one, and although it is written ostensibly for the benefit of the boy the man will be just as much interested in reading it. No one is better qualified to talk about Mr. Edison than is Mr. Meadowcroft, for the two have been intimately associated for many years, and the story as told by the author has been read carefully by Mr. Edison himself and is published with his consent.

There are twenty-five chapters to the book dealing with Mr. Edison's boyhood and the various phrases of his active career, arranged in chronological order. The chapters relating to his telegraphic experiences are deeply interesting, and the old story has been told in a new way, with a different light thrown upon it.

The story of Mr. Edison's life is always inspiring to young and old alike, and this latest volume appears at a time when it should meet with a large demand for the Christmas trade. It is published by Harper & Brothers, New York, and contains a recent picture of Mr. Edison as the frontispiece. It has 332 pages and is printed in clear large type. The price of the book is $1.25, and copies are for sale by TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

Submarine Telephone Cables Around New York.

It is doubtful whether the average telephone patron, in talking to a distant person, realizes the time and labor involved in providing the facilities for the purpose. As a rule he is inclined to take such conveniences as a matter of course.

An interesting article in the *New York Telephone Review* tells by the aid of several illustrations how a submarine telephone cable was laid under the North River from Manhattan to Jersey City, N. J.

There are now sixty-three armored submarine telephone cables leading from Manhattan Island in all directions with a total number of pairs of conductors of 10,684. In addition, there are three cables laid in the subways of the Pennsylvania Railroad and five cables in a telephone subway across the Harlem River, which total 2,877 pairs. This makes seventy-one cables and 13,561 pairs of conductors (27,122 wires) passing under the North, East and Harlem Rivers.

In laying these submarine cables the utmost care must be exercised not to have them cross each other. They must occupy the same relative positions in the cable houses on each side of the river. By being chained as low as possible there is little slack for an anchor to catch, and the cable is far enough from the surface to avoid being caught by a propeller.

Those responsible for laying and maintaining these cables have learned by long experience how to meet and solve the problems connected with the work. By making use of the best methods little trouble is met as a general rule, and consequently there are few interruptions to the service.

Statue of Lord Kelvin.—A statue of the late Lord Kelvin is to be erected in Glasgow. Lord Kelvin was Sir William Thomson, whose inventions include the siphon recorder used on submarine cables, and many other telegraphic devices.

Annual Meeting of the Telegraphers' Mutual Benefit Association.

The forty-fifth annual meeting of the Telegraphers' Mutual Benefit Association was held at 195 Broadway, New York, November 15, vice-president Charles P. Bruch occupying the chair in the absence of President Belvidere Brooks.

After the reading of the report of the committee on credentials, which consisted of Messrs. F. D. Bermke, of Chicago; J. W. Collins of Washington, D. C., and G. H. Mills, of Providence, R. I., the report of president Brooks was read.

He called attention to the heavy mortality during the year, rendering it necessary to expend the entire income from assessments and interest, as well as to borrow $1,997.41 from the reserve fund to provide the payment of 105 death claims, amounting to $104,500. This is by far the largest amount for benefits paid by the association in any year, making the total amount paid to the beneficiaries of deceased members from date of organization $1,671,207.

One hundred and sixty-eight applications for membership in the full grade and 72 in the half grade were received during the year, a number which was not sufficient to provide for any increase of membership in the full grade after lapses and deaths were deducted. He pointed out that the responsibility for growth and expansion rests upon each and every member. Among the deaths during the year were two of past officers of the Association, namely, David R. Downer, who was secretary from 1867 to 1869, and Clarence Cary, president from 1881 to 1883. In accordance with the resolution passed at the last meeting the following members were invited and consented to act as the advisory board to promote the extension of the membership: Messrs. B. E. Sunny, president Chicago Telephone Company, Chicago, Ill.; H. J. Pettengill, president South Western Telegraph & Telephone Company, Dallas, Tex.; J. N. Kellar, president New England Telephone and Telegraph Company, Boston, Mass.; W. T. Gentry, president Southern Bell Telephone and Telegraph Company, Atlanta, Ga.; A. L. Salt, Western Electric Company, New York; H. C. Worthen, general superintendent Western Union Telegraph Company, Atlanta, Ga.; G. H. Usher, general superintendent Postal Telegraph-Cable Company, Atlanta, Ga.; G. E. Paine, general superintendent Postal Telegraph-Cable Company, Chicago, Ill.; C. H. Gaunt, general superintendent Western Union Telegraph Company, San Francisco, Cal.; J. G. Blake, general superintendent Postal Telegraph-Cable Company, San Francisco, Cal.; J. C. Nelson, general superintendent Western Union Telegraph Company, Denver, Col.

The reports of the secretary, the treasurer and the auditing committee were then read.

The secretary's report showed that there were 4,514 full-grade members on September 30 and 798 half-grade members.

The ratio of deaths per thousand of full-grade members was 20.62 and of half-grade members 8 82. and the average age of deceased members was 60 years in the full-grade and 40 in the half grade.

The report of the treasurer shows total receipts of $124,417.91, including interest on reserve fund and deposits, amount received from secretary, received in payment of loans, and from reserve fund for investment.

The disbursements included $104,500.50 for death claims, $6,497.00 for general expenses and $9,200 new loans and investments. The sum of $13,580.82 is held uninvested in reserve fund after deducting a loan of $1,997.41 to the current account.

Vice-president Bruch invited the agents present to give their views as to the difficulties met with in securing new members, and a lengthy discussion ensued. The majority of the speakers believed that the greatest benefit would be derived by giving the secretary competent assistance in order to enable him to make periodical visits to the larger cities where there is a field for personal solicitation. The matter was referred to the executive committee with power.

The constitution and by-laws were amended fixing the date for holding the regular annual meeting of the Association on the second Wednesday of March instead of the third Wednesday in November as heretofore. This action was taken in order to avoid the duplication of labor involved in the preparation of two reports, one for the members at the annual meeting and one for the state insurance department, under whose jurisdiction the Association is conducted. It was therefore resolved that the next meeting of the Association be held in New York on Wednesday, March 14, 1913.

In accordance with the resolution passed at the last annual meeting, section 2 of article IV of the constitution was amended to provide that the executive committee consist of six members, and that the officers and past presidents of the association shall be *ex-officio* members of the committee.

The election of officers resulted as follows: President, Belvidere Brooks; first vice-president, Charles P. Bruch; second vice-president, S. S. Garwood; secretary, M. J. O'Leary; treasurer, A. R. Brewer. Members of the executive committee, to serve three years, E. J. Nally and W. J. Lloyd. Auditing Committee, H. D. Reynolds, T. E. Fleming, W. J. Dealy.

Mr. James Merrihew resigned as a member of the executive committee and the vacancy was filled by the election of S. H. Marriot, auditor of receipts American Telephone & Telegraph Co., Long Distance Lines Department. Mr. Merrihew, being a past-president, is an *ex-officio* member of the executive committee.

Those present were:

Boston—P. J. Farrell.
Bradford, Pa.—J. E. Golden.
Buffalo, N. Y.—H. D. Reynolds.
Chicago—F. D. Bermke.
New York—W. E. Athearn, W. J. Austin, W. H. Baker, W. H. Brahe, T. Brennan, A. R. Brewer, C. P. Bruch, R. I. Courtney, F. E. Coyle, C. M.

The San Francisco Western Union Office.

On November 12, 1907, San Francisco's main office of the Western Union Telegraph Company was moved from West Oakland, at which point it was established at the time of the great conflagration on April 18, 1906, to the corner of Pine and Montgomery Streets, San Francisco. The home-coming was looked forward to with much pleasure. The move from the temporary frame building on the Southern Pacific right-of-way, which housed some two hundred operators for over two years, to more comfortable quarters in a brick structure was made one Saturday night and Sunday and the task of moving switchboards, dynamos and the instruments a distance of about six miles, together with the numerous connections necessary in the underground and submarine cables was accomplished without interruption to traffic. The force had by that time however learned how to overcome difficulties and meet emergencies. For two and a half years while the rehabilitation of San Francisco was going on a large volume of business was handled at this temporary office under the most trying conditions. The greater part of the force was picked up almost destitute and had to be clothed, fed and housed until they could get a fresh start. The equipment was quickly assembled from different parts of the United States and there was nothing uniform, in other words it did not fit. The supply of electric power was unreliable and there was a very troublesome gas engine for reserve. The working tables were made of rough boards; the facilities were crowded; the wind whistled through the cracks and the rain dripped from the ceiling, so there was great joy when these things were left behind.

At that time it was believed that the company was moving into quarters adequate to provide for many years growth, in fact some space was leased to outside parties, but the business and organization has long since outgrown its confines and the adjoining building has been annexed as well as a portion of another across the street. The growth of San Francisco was not stunted by its partial destruction; it is now a more beautiful city and the same large commercial center. With it grows the business of the Western Union and with the opening of the Panama canal and the building of the great exposition the company will be reaching out for more room within the next two years.

Many of the older executive heads who have faithfully carried the burden of their duties for years have transferred their charges to younger and more energetic men who are thoroughly alive to the situation and who are fast making the service popular, and at the same time making their employes more comfortable. There are both women and men's rest rooms furnished with easy chairs and lounges, and there is a matron in charge of the women's room where tea, coffee and light lunches are served.

There is a telephone office adjoining the main operating room where telegrams are received and delivered by telephone. It is complete in every respect, and lately the telegraph multiplex sets, dynamos and switchboards were moved to the fourth floor and with credit to division plant superintendent R. W. Gray, San Francisco possesses one of the best equipped and wired multiplex rooms of the system. Presiding over this room are Messrs. W. H. Wilson, T. J. Crow, S. B. Mills and G. H. Gilbert, days, and Messrs. J. A. Lowery, W. A. Warrensford and E. C. Davis, nights,—all competent wire and equipment men.

In the annex, adjoining the main operating room are located the printers and Wheatstone sets. This department is in charge of Messrs. R. W. Wells and W. L. Glasheen, printer experts, assisted by G. Hohenschild and J. W. Biller.

Mr. H. S. Converse is day chief, Mr. C. E. Donnelly night chief, Mr. A. A. Marlatt first trick traffic chief, assisted by Messrs. C. A. Rawlinson, J. E. Mifka and S. N. Shaplin. Mr. T. McGuiness is second trick traffic chief and Mr. O. D. Walters all night chief, assisted by Messrs. C. F. Woodward, J. B. LeCompte and W. R. Melville.

Quick Restoration of Telephone Service in Kansas City.

The Missouri and Kansas Telephone Company's Fairmount Exchange at Kansas City, Mo., was completely destroyed by fire at 3 a. m. Sunday, October 22. The telephone company at once communicated with the Western Electric Company and the work of restoring service to the subscribers was begun at 9:00 o'clock of the same morning. The Hawthorne factory of the Western Electric Company was called upon by long distance telephone to make a hurry-up shipment, and it sent the necessary apparatus by express the evening of the day on which the fire occurred. Twenty-six installers reported for work on Monday morning, October 23, and from that time until the new board was cut in service at 5:00 a. m. October 26, with a full equipment of 800 subscribers' lines, a day and night crew were at work continuously.

Mr. Irwin's Experiences on the Air Ship "America."

The following interesting story by Mr. John R. Irwin, wireless operator of the airship "America," is published in the "Marconigraph" of London. It was the object of the expedition, it will be remembered, to make the passage from America to England by means of the airship, but the ship was lost at sea and the rescue of its crew by the steamer "Trent" is still fresh in the minds of the people.

Mr. Irwin's story is as follows:

In August of last year I was assigned to duty on the airship "America," then in course of construction at Atlantic City, N. J. On October 15, at 8 a. m., the airship left Atlantic City, and by 10 a. m. on the same day I had joined my earth to the equilibrator and opened communication with the station on one of the Atlantic City piers.

The quarters allotted to the wireless apparatus on the vessel were certainly the strangest an operator ever found himself in. Under the main car of the huge dirigible was suspended a lifeboat 27 ft. long, with a 6-ft. beam and 4½ ft. in depth. At each end was a 9-ft. water-tight compartment, and the forward one was divided off into a 2-ft. compartment, opening into the cockpit. This was the Marconi cabin. In this space my small set was placed while I worked from the open cockpit.

The Marconi Company had guaranteed Mr. Vaniman only a 30-mile radius with the set installed, which consisted of a 10-in. coil (worked from 25-volt accumulators) with a specially constructed loose-coupled jigger, field type of magnetic detector, and a small variable condenser. To recharge our batteries we carried a small 25-volt dynamo, which was belted to one of the main engines. As an antenna we used the main car of the airship, consisting of hundreds of feet of steel tubing, tanks and wire, with a capacity unknown. The celebrated equilibrator, consisting of 40 steel tanks filled with gasoline, threaded on a ½-in. steel cable, which, trailing in the sea, was used as a "ground."

I never experienced such a feeling of joy and relief as I did when "Ax" reported signals good and strong. All the members of the crew had their eyes on me, and all realized what an important part wireless would play in the expedition. Until 4 p. m. on the day of the start I maintained constant communication with Atlantic City, sending bulletins of our progress and receiving encouraging messages and weather reports from the shore. An hour later, although able to read every station along the coast, I was unable to reach any of them. I estimated that we were fully 100 miles off shore, and was particularly pleased with the success of the apparatus so far, and trusted to communicate with incoming liners from Europe during the night. We had departed in a dense fog, and on leaving the hangar, we were lost to view in less than a minute. This fog lasted for two days and nights, and everything was saturated with water. It also added great weight to the lifting capacity of the airship, and resulted in the car flying very low to the water. During the first night we passed three vessels, and almost collided with a big, four-masted schooner, which we missed by less than a ship's length. This was our first "thriller." During the night I repeatedly tried to communicate with vessels, but without success. With the immense aerial I had, the signals came in like hammers, and gave me the impression they were nearer than they actually were.

At 9 a. m. I communicated with Siasconset (my old station), remaining in touch with it until 1 p. m. During the previous night a mishap occurred to the engine to which the dynamo was attached, the ball bearings in the shaft being defective, and we were obliged to shut down. I was then unable to recharge my batteries and began to economize on my electric energy. On Sunday afternoon the wind developed into a gale with a very rough sea, and it was then that our troubles began. The constant condensation of fog on our immense gas-bag was still keeping us too close to the water; some of the gasoline was therefore jettisoned, and when night fell the contraction of the hydrogen gas again brought us perilously near the sea. We were forced to throw overboard the now useless engine and dynamo. This relieved the strain of the jerking equilibrator, and the night passed without further danger.

All Sunday night I could hear the steamer "Main," and called at intervals. The vessel appeared tantalizingly close. No one can realize my disappointment when I failed to get in touch with it. At this time we were driving along with a 45-mile wind taking us in a south-easterly direction and out of our course. On Monday, the third day out, the wind slackened somewhat, and took us due south. All prospects of reaching Europe had gone, and we began to think seriously of some way to get back home. Monday turned out to be a beautiful, warm day, and the expanding gas caused the airship to soar thousands of feet skyward, the highest altitude we attained being 11,900 ft. I felt nothing unusual at this high altitude, but had a peculiar ringing sensation in my ears when ascending and descending. Monday night was to prove an eventful one. We had a glorious moon, and all hands stood watch, keeping a sharp lookout for a ship. I heard a Royal Mail boat working during the earlier hours of the night, and realized that she might be bound our way from the West Indies.

At 3 a. m. Tuesday, Mr. Wellman called all hands with the glad tidings of "ship in sight." I immediately called C.Q.D. and S.O.S., but received no response. So, seizing an electric torch, I commenced calling in Morse lamp fashion. After some little delay I was answered by the steamer. I conveyed to them by lamp the fact that we were equipped with wireless, and in a few minutes the most welcome signals I ever heard came hammering in my telephones.

Digitized by Google

The steamer proved to be the Royal Mail S. S. "Trent." From this time, until we launched our lifeboat at 8 a. m., we were in constant communication, receiving and sending orders, advice, and suggestions. We were then drifting at the rate of 12 miles an hour, and asked Captain Downs to follow us till daybreak, when we would be better able to see how we could free ourselves from the airship.

The "Trent" was then from 10 to 15 miles distant, and by 7.30 a. m. was alongside. We then informed them by wireless that we would descend and launch out boat the gas valve was opened, and gradually we descended to the water. When within 6 ft. the boat releases were opened, and she fell beam on into the sea, which was fairly rough at the time. She lurched gunwale under several times, shipping several inches of water. She then righted, and the heavy steel equilibrator struck us as the gasbag shot skywards. It knocked a hole in the air compartment of the boat containing the wireless apparatus. This, however, did not impair the stability of the boat. I also got a stunning blow in the forehead. Before we could recover from this excitement, perhaps the most anxious moment of the three eventful days occurred. The "Trent," about 100 yards away, bore right down on us, making 17 knots. It looked as if nothing could save us from being run down. She missed us, however, and, after a narrow escape from swamping, we fell astern about two miles. The steamer came about and ranged alongside us. Once more ropes were thrown, but she was making too much headway for us to hold them. They next came to us stern on, and in a few minutes we were aboard, boat and all.

In July of this year I returned east, and was offered the position of Marconi operator with Vaniman's new airship, "Akron," in which he will again tempt the fates in an attempt to reach Europe by dirigible balloon. I promptly accepted, and am now assisting in its construction. The new airship will be 258 ft. long; it will contain 400,000 cubic feet of hydrogen, and will have a lifting capacity of 13 tons. It will have a total maximum engine capacity of 317 horse-power, and will carry a 3-kw. Marconi set of special construction.

Mr. J. S. Berger, manager of the Lexington, Ky., Western Union office, writes: "While I have been a subscriber to your journal only one year I must say that it is a very interesting paper, and I look for it on the first and sixteenth of each month as much as I do my salary."

There is something of value to everyone in each issue of TELEGRAPH AND TELEPHONE AGE, and this value should not be measured by the cost of a subscription but by the influence the paper has on the individual.

QUESTIONS TO BE ANSWERED.

[One of the most effective means of imparting information is to ask and answer questions, the value and power of this method being due to the fact that the information given in an answer is specific and direct. Asking questions for the student to answer for himself has proved to be an excellent means of education, as it promotes and encourages concentration of thought and investigation in order to arrive at the correct answer. There is a general demand for knowledge on the quadruplex, duplex, etc., and to aid in the acquirement of such knowledge we are extending our help to students by asking questions on these subjects in each issue of our journal, so that they may be encouraged in their studies by answering them. We use as our text book Maver, and Davis's "The Quadruplex," and students should have a copy of this book at hand in order to be able to give the answers. The questions are progressive and a careful reading of the book on the points under inquiry unfolds the answers. This method of acquiring technical knowledge is a fascinating one.]

TELEGRAPH REPEATERS.

Why are repeaters necessary on telegraph lines?

How does electricity escape from telegraph wires?

What law causes a weakening of current on telegraph lines?

What is accomplished by inserting repeaters on long lines?

Is it necessary to insert repeaters on short lines?

What is the general rule for determining the intervals between repeaters.

How did Prof. Morse propose to obtain the best effects on a telegraph line?

What were the objections to his proposed method?

How much did Prof. Morse's first magnets weigh?

Why were Prof. Morse's early electromagnets feeble in action?

How did Prof. Morse propose to prolong his circuit?

What name did he give the instrument he used to repeat from one section of his line into another section?

When was the Woods button repeater introduced?

Why is it necessary to use a "button" in this form of repeater?

Name some of the advantages of this repeater.

What is the principal objection to this form of repeater?

Who was the inventor of the first automatic repeater?

In what principal respect does an automatic repeater differ from a button repeater?

Of the many automatic repeaters invented which one was adopted as the standard by the Western Union Telegraph Company?

What repeater is generally used in Canada?

Trace the connections of the Milliken repeater.

Why are the transmitters of Milliken repeaters provided with buttons, or switches?

On what notable circuit was the Milliken repeater formerly used?

ADDRESS ALL COMMUNICATIONS TO
J. B. TALTAVALL, - - - Publisher
253 BROADWAY, NEW YORK.
T. R. TALTAVALL, Editor.
R. J. WEEKS, Manager Advertising Department.

CABLE ADDRESS: "Telegage," New York.
Telephone: 6657 Barclay

CHANGES OF ADDRESS.—In ordering a change of address the old as well as the new address must be given.
REMITTANCES to Telegraph and Telephone Age should be made invariably by draft on New York, postal or express money-order, and never by cash loosely enclosed in an envelope. By the latter method money is liable to be lost, and if so remitted is at the risk of the sender.

December 1, 1911.

The Passing of 195 Broadway.

The building known as One-ninety-five Broadway, New York, the Mecca of American telegraphers, with all of its associations and traditions, is doomed to demolition. It does not measure up to the standard of modern business requirements so it has been practically decided to pull it down and erect in its place a modern "sky scraper." As it has been aptly stated, the income of the present building is too low in proportion to the value of the site upon which it stands and there is only one way to increase the revenue-producing power and that is to build a structure of the modern type. When the present building was erected in 1872-1873 it was a model of its kind, but in the rapid march of progress standards of today become obsolete to-morrow. There were no steel cage structures in those days, the walls being depended upon for strength and support.

It has often been remarked that much valuable space in the present structure is filled with mortar and brick, and so there is, viewed from the present-day standards.

While there will be thousands who will regret to see the old building go, there is a little consolation left in the thought that the change will not take place in its entirety at once. The rear section of the structure, on Dey Street, will, according to announcement, be erected first, and the main section, on the corner of Broadway, later. The company's plans as to details are not sufficiently matured to enable us to give even an approximate outline of the final work.

The Telegraphers' Mutual Benefit Association.

The Telegraphers' Mutual Benefit Association is an organization that the great telegraph and telephone fraternities should be proud of, for it has a standing among fraternal organizations that probably has never been equalled, yet with a little effort on the part of its members it could easily be made twice as strong as it is. There is a point in this connection that perhaps not all of the members realize and that is the greater the number of young members brought into the association the less will be the cost to the individual members for their insurance. The young men are easier to bring into the society, and every present member should exert himself to gain an additional one and thus, while making the association stronger, reduce the cost to himself.

The report of the association for the fiscal year just closed, which is summarized on another page of this issue shows the association to be in a satisfactory condition. It has paid out to beneficiaries of deceased members no less than $1,671,000 since its organization. This is an excellent record for an organization of limited membership, and the figures represent comfort and relief from want in many homes.

Of the thousands of telegraph and telephone employes throughout the country only a small percentage are members of the association and there is no good reason why this disproportion should be so great. Every member should help to build up the organization and aid in making its position stronger by adding to its membership.

Independent Thinking.

One great trouble with the world today is the lack of independent thinking. Thinking is mental work, and a great many people abhor work of any kind. They are satisfied to let others do the thinking for them as that relieves them of the trouble. They are simply followers and rarely have any ideas of their own. The leader is always one who thinks for himself, and it is by reason of this fact alone that he is a leader. The follower consciously or unconsciously looks up to the leader for direction. If he is in doubt about anything he is likely to think or do as his model does and rarely ever thinks of investigating for himself the facts and truth of the subject in hand.

The masses place too much confidence upon what others say, and those who do the saying and leading, fully understanding this weakness of human nature, are in a position to take advantage of the weaker mentality of their brothers if they are so inclined.

This explains why so many people yield to the plausible stories of promoters of shady enterprises and part with their money on the promise of large financial returns. If the victims would take the trouble to investigate these schemes themselves before yielding to the allurements of the wily promoter, there might not be so many "get-rich-quick" concerns for Uncle Sam to place on the black list. The men at the head of these schemes are thinkers, and they know full well

Digitized by Google

that they would not find their illegal schemes profitable if all men were thinkers too.

If people would do their own thinking and not allow themselves to be wholly controlled by the minds of others, there would be much less discord and unhappiness in the world.

Patenting Inventions.

Telegraphers in general, are a bright and wide awake lot of men, and as a rule have had varied experiences. Most of them are observing and are not satisfied with what they see on the surface; they want to know the why's and wherefores of things and they become investigators and thinkers.

Being associated with telegraph instruments of all kinds, chemical batteries, etc., they naturally acquire a desire to learn how the instruments are constructed and why they work, and how and why the mixing of certain chemicals in water produces electricity. Many telegraphers think deeply on these things and in many cases their investigations and study lead to inventions and improvements in the apparatus around them. When they accomplish such results they are naturally elated, and it is just at this point that they are in danger of being led into trouble.

It is very easy for a novice to believe that what he discovered in his investigations or what improvement he thinks he has made over existing methods, is new, and the first thing he turns his attention to is to procure a patent. Right here is where he needs advice and the exercise of sound judgment. In eight cases out of ten he will find, on investigation, that many others have travelled over the same ground and accomplished what he has done in perhaps a better way. Therefore it is always safe to "make haste slowly" when the patentability of an invention is concerned.

Our advice is frequently asked as to patenting so-called inventions. We never hesitate to recommend that the case be put into the hands of a reliable patent attorney with a request to make a search of the records at Washington to see if the same thing has not been patented before.

Quite recently we were requested by a gentleman to aid him in getting a patent on what he thought was something new. We advised him to have a search of the records made and gave him the name of a reliable attorney to look into the matter. The attorney found that the same thing had been patented years before, and what the gentleman thought was really a new thing turned out to be an old idea. He saved many dollars by taking this precaution. If he had applied for a patent, without a preliminary investigation, it would have cost him at least ten times the price of the search before he found out that his invention was not new and someone else had preceded him.

Any one who has a tendency toward improving and inventing things should keep posted as to what others have done along the same line of work. This can be done only by reading the records bearing upon the particular subject, and before he has gone far in his search he need not be surprised if he learns that others have done the same thing before, in a better way perhaps.

We do not want it to appear that we are discouraging invention. Far from it; we encourage it at all times. The point we wish to make is that if a person thinks he has discovered something new he should first ascertain what others have done along the same line, and if he learns that he has a reasonably clear road to himself, then have a search made in the patent office for anticipations. If this results in a favorable report then make the application for a patent, and not before.

The Way to Rise.

Abraham Lincoln once said: "The way for a young man to rise is to improve himself in every way he can, never suspecting that anybody wishes to hinder him.

"Allow me to assure you that suspicion and jealousy never did help any man in any situation. There may sometimes be ungenerous attempts to keep a young man down; and they will succeed, too, if he allows his mind to be diverted from its true channel to brood over the attempted injury.

"Cast about and see if this failing has not injured every person you have ever known to fall into it."

Taxation of Telegraph and Telephone Properties in Ohio.

The Ohio State Tax Commission has fixed tentative valuations upon a few of the large telegraph and telephone properties.

Increases in the valuation of telegraph properties in the State are as follows: Postal Telegraph-Cable Company, from $397,550 to $796,500; Western Union Telegraph Company, from $2,335,375 to $4,045,680; Put-in-Bay Telegraph Company, from $1,800 to $5,000.

The valuation of telephone properties was fixed last year at $21,000,000; this year it is believed the figures will reach $55,000,000.

Competition in Public Utilities.—A novel point with regard to the effect of state regulation of public utilities has been raised by the New York Edison Company in relation to the competition that it appears it will now have to face from the Long Acre Electric Light and Power Company. It contends that since in its service and rates it is obliged to submit to the regulations laid down by the Public Service Commission, it is the duty of that commission to protect it against competition. It further demands that if competition is permitted in its most profitable districts, it be relieved of regulation and allowed to meet competition in those districts at competitive rates without reference to the rates in non-competitive districts.

The best way to keep posted in telegraphic and telephonic progress is to read TELEGRAPH AND TELEPHONE AGE. Subscription price $2 per year.

Course of Instruction in the Elements of Technical Telegraphy—IV.

(*Copyrighted.*)

(Continued from page 770, November 16.)

We began in our issue for October 16 the publication of a course of instruction in technical telegraphy. The course is published for the benefit of those of our readers who desire to fit themselves for better positions in their vocation. It is elementary throughout and will be divided into chapters, following one another in logical order.

The course has received the hearty commendation of telegraph officials and experts for its scope and accuracy and its sound practicability. In each chapter examples will be given in order to illustrate the application of the rules to practical cases, and each chapter will be followed by a series of questions pertaining to the subject of the chapter, to be worked out by the student in order to review his progress.

The mathematical section which is now running will carry the student through fractions, decimals, proportion, elementary algebra, etc.

DECIMALS (*Concluded.*)

RULE (8). *If in dividing one whole number by another there be a remainder, annex ciphers to the remainder and continue dividing until there are three or four decimal places in the quotient, and then if there still be a remainder, terminate the quotient by the plus sign (+), which shows that it can will be a whole number.*

Example: Divide 19 by 7.

Solution:

$$7\,|\,19.0000$$
$$2.7142 + \text{ Ans.}$$

RULE (9). *When the divisor and dividend contain the same number of decimal places the quotient will be a whole number.*

Example: Divide 1.5 by .5.

$$.5\,|\,1.5$$
$$3. \text{ Ans.}$$

RULE (10). *When the divisor contains more decimal places than the dividend, supply the deficiency in the dividend by annexing ciphers..*

Example: Divide 20 by .05.

Solution: There are two more decimal places in the divisor than in the dividend, therefore annex two ciphers to the latter, thus, 20.00.

By Rule 9 the quotient is now in units, or whole numbers.

$$\frac{20.00}{.05} = 400 \text{ Ans.}$$

Example: Divide 8 by .3.

Solution: Supplying the deficiency in the dividend gives 8.0.

Dividing, $.3\,|\,8.0$

26. and 2 remaining.

Carrying out to four decimal places gives

$$.3\,|\,8.00000$$
$$26.6666 + \text{ Ans.}$$

NOTE: The dividend has now four more decimal places than the divisor, and by Rule 7 four decimal places must be pointed off in the quotient.

PROPORTION.

Two quantities are said to be *directly* proportional, or simply proportional, when any two values of the first quantity have to one another the same ratio as the corresponding values of the second.

Thus, when two quantities are connected in such a way that when one is increased two, three, four, ... times, the other is also increased two, three, four, ... times, they are in direct proportion.

Two quantities are *inversely* proportional when any two values of the first quantity have to one another the inverse ratio of the corresponding values of the second.

Thus, when two quantities are connected in such a way, that when one is increased two, three, four, ... times the other is diminished two, three, four, ... times, they are inversely proportional.

A proportion may be indicated by the double colon : :, or the sign = .

Thus, 8 : 4 : : 6 : 3.

or 8 : 4 = 6 : 3

are the two ways of expressing the proportion which is read: 8 is to 4 as 6 is to 3, or, the ratio of 8 to 4 is equal to the ratio of 6 to 3, which means the same as $\frac{8}{4} = \frac{6}{3}$.

In proportion the terms are numbered first, second, third and fourth.

The first and fourth terms are called the *extremes;* the second and third terms are called the *means.*

RULE (1). *In any proportion the product of the means equals the product of the extremes.*

Thus, in the proportion

12 : 10 : : 6 : 5

$12 \times 5 = 60$, is the product of the extremes, and equals $10 \times 6 = 60$, the product of the means.

RULE (2). *The product of the extremes divided by either one of the means gives the other mean.*

NOTE: When one of the terms is not known let x or some other letter represent it.

Thus, 8 : 6 : : 20 : x.

Example: Find the second term in the proportion

8 : x : : 20 : 15.

Solution: The product of the extremes is $8 \times 15 = 120$.

Dividing by the given mean.

$\frac{120}{20} = 6$, or the second term. Ans.

RULE (3). *The product of the means divided by either of the extremes gives the other extreme.*

Example: Find the first term in the proportion.

x : 6 : : 20 : 15.

Solution: The product of the means is $6 \times 20 = 120$.

Dividing by the extreme;

$\frac{120}{15} = 8$, or the first term. Ans.

Digitized by Google

Before solving any proportion cancel any factor which is common to the first and second terms. Thus, in the proportion

$$8 : 6 : : 20 : x$$

the common factor 2 may be cancelled, leaving

$$\overset{4}{\cancel{8}} : \overset{3}{\cancel{6}} : : 20 : x.$$

$$20 \times 3 = 60.$$

$$\frac{60}{4} = 15, \text{ or } x. \quad \text{Ans.}$$

In all cases of proportion there are three terms given; the fourth has to be found. It does not matter where x, or the unknown term, is placed; it can always be found by applying the above rules.

The first question the student must ask himself in every calculation by proportion is: "What is it I want to find?"

Example: If 45 sheep cost $565 what will 140 sheep cost? Here it is cost that is wanted, so if x, or the required cost, be made the fourth term of the proportion, the given cost in the problem will be the third term. $565 will therefore be the third term of the proportion. Of the two remaining numbers given in the problem the *greater* will be the second term when the answer is to be *greater* than the third term, and the *less* will be the second term when the answer is to be *less* than the third term.

In this case 140 sheep will cost more than 45, therefore 140 will form the second term and 45 the first, giving,

$$45 : 140 : : \$565 : x$$

$$\frac{565 \times 140}{45} = 1757\tfrac{7}{9}.$$

Therefore, $x = \$1757\frac{7}{9}$. Ans.

Example: If 9 men can build a wall in 15 days how long will it take 5 men to build it?

The 15 days is the third term since the answer is to be in days.

It will take 5 men longer than 9 men to build the wall, therefore the proportion is

$$5 : 9 : : 15 : x.$$

$$x = 27 \text{ days.} \quad \text{Ans.}$$

(To be Continued)

The Balloon as a Wireless Telegraph Receiving Station.*

BY P. LUDEWIG.

As very little has been published regarding the wireless stations which are fitted on balloons, the author determined to describe some tests on this subject made by him at the beginning of the year. The object of these tests was to pick up with the simplest arrangement of apparatus the waves sent out from wireless land stations.

The crux of the problem lay in the arrangement of the antenna, which was made in two parts, between which the receiving apparatus was connected. As regards the receiving apparatus itself, a choice was made of those employed in practice.

The following was the arrangement employed: When the balloon was half filled a wire was wound round the equator of the gas bag, being interwoven through the protecting cordage; and the end of the wire was placed in the basket. This wire formed the upper half of the antenna. To form the lower half a heavy wire was dropped from the basket after the balloon had risen.

As the object of the tests was to discover with how simple means picking up of messages was possible, a very simple apparatus was chosen. A Schlömilch cell was used as receiver, and this was connected direct to the antenna, in order that the room taken up should be as little as possible. With this arrangement accurate tuning was, of course, impossible. Approximation to the wave length of 500 metres at the sending station was obtained when the wire from the basket was 125 metres long, or equal to one-quarter the wave length.

The choice of some simple receiving station also solved the problem as to whether damped or undamped waves should be used for sending, the small tuning capacity of the receiving station making the use of the first-named a necessity. As sending station the 30 m. (100 ft.) high "T" antenna at the Electrotechnical Institute of the Frankfort Physical Society was used. This station employs the Braun method, hightly damped waves with close coupling being used.

During the first tests in March, 1911, which lasted two hours, the balloon was 50 km. (31¼ miles) away at a maximum height of 600 m. (2,000 ft.) from the ground. At this height the signals received were not so clear as when the balloon was lower down.

During a second test on March 23 three balloons were used, the stations at Göttingen, Darmstadt, Karlsruhe and Frankfort being employed for sending. The first three of these transmitted singing sparks, the latter working on the Braun system with a frequency of 50. The signals from Frankfort and Darmstadt were heard quite easily, but the other two could not be heard. During the time Göttingen was sending, signals with a frequency of 50 were received, and a message was received so quickly as to be unintelligible. Subsequent inquiries show this to have been transmitted from the balloon belonging to the Telegraph Battalion at Coblentz.

*Abstract of an article in the "Physikalische Zeitschrift."

New News Association.—The American Telegraph Press, Inc., has been organized in Washington, D. C., to gather and distribute news. Mr. Winfield Jones, of Washington, is president and general manager; G. Grosvenor Dawe, vice-president; Dr. Clarence J. Owen, secretary and treasurer, and A. E. L. Leckie, general counsel. The American Telegraph Press plans to operate in fields which its projectors consider are not fully covered by the other large press associations of the country, and in addition will conduct a feature and general news service from Washington. It will start immediately with a leased wire service between Washington and New York, extending its wires to other places as rapidly as possible. The headquarters of the corporation will be in Washington.

Multiplex Telephony and Telegraphy.

In discussing the paper of Major George O. Squier, entitled "Multiplex Telephony and Telegraphy by Means of Electric Waves Guided by Wires," read at the Chicago meeting of the American Institute of Electrical Engineers, Dr. Frank B. Jewett stated that the problem of applying a high-frequency method of transmission to an existing wire plant would be an exceedingly difficult one. Furthermore, if the system were to be of any great value in a commercial plant it could not be limited to a single frequency, but would require a large range of frequencies. With such a range of frequencies the range of energy which must be supplied to lines of similar length will be very great if uniform transmission is to be given. While this might not be a serious objection in a plant comprising only a few toll lines, it becomes one of very great importance when a comprehensive net work has to be taken into account. He did not see how this difficulty could be overcome in a way that would admit of applying this kind of a system to the complicated requirements of a commercial wire plant. Referring to transposition of wires he said that on well transposed lines for ordinary talking circuits the transposition poles occur on the average at between one-half and one mile apart, say, from twenty to forty poles apart. When we come to consider high-frequency currents of from 15,000 to 100,000 alternations, with their very much shorter wave length, the same number of transpositions per wave length would require additional poles. He had failed to satisfy himself that there is any affirmative answer to the engineering questions which must be satisfactorily answered before there is any possibility of applying Major Squier's invention generally to a commercial plant used for universal service.

Mr. John B. Taylor said that the system of multiplex telephony under discussion is a resonance method making use of intensity variations in the strength of an alternating current of frequency greater than that to which the standard telephone receiver and human ear are sensitive. Major Squier refers to the possibility of solving the problem by the use of a similar method in which the transmitted alternating currents are of frequency below those to which the ear is sensitive, or in the neighborhood of 16 cycles per sec., but has apparently dismissed this from serious consideration on account of the difficulty of securing a pure sine wave. It may be well to point out here that entirely apart from any question of difficulty in securing a perfect sine wave of the frequency of 16 cycles or lower, that such a system is fundamentally wrong for purposes of speech transmission. Fairly rapid speech may have as many as ten distinct syllables in each second, so that one or more of these syllables occurring at or near the zero part of the 16-cycle wave, would be either entirely lost, or of such low intensity compared with those syllables occurring at or near the peaks of the 16-cycle wave, as to seriously change the quality of the speech. This is not equivalent to saying that speech over such a low frequency system could not be recognized, but that the distortions are so great as to debar the matter from serious practical consideration.

Mr. S. G. McMeen, in referring to Dr. Jewett's comments, said all reactances required in Major Squier's methods, whether of capacity or inductance, are of small dimensions because of the high frequencies. Dr. Jewett said that Major Squier's invention was "a beautiful laboratory apparatus," but he (the speaker) reminded him that the telephone itself was that, and that only, when Professor Bell finished it.

Mr. Frank F. Fowle stated that Major Squier's achievement in duplexing a telephone circuit by superimposing waves of a frequency beyond the range of audibility, will rank high among scientific accomplishments.

Mr. Béla Gáti, of Budapest, Hungary, gave an account of some experiments made by himself in high frequency telegraphy and telephony. With high frequency currents, he said, the speed is unlimited. He succeeded in sending from 20 to 60 letters per second. The signals were not intermixed, and the incoming signal was not expanded as in direct-current telegraphy. He had made experiments over a 4,000-km. (2,500-mile) line on which the direct-current signals were expanded perhaps 300 per cent, while the alternating-current signals were not expanded at all.

Referring to telephoning with high frequency currents he said he had proved mathematically the possibility of talking between London and Kurachi, India, a distance of 8,000 kilometers (4,970 miles).

Telegraphers of Today.

An excellent opportunity is offered to telegraph people in general to become acquainted with over 600 prominent telegraph officials and others identified with the telegraph, the railroad, the submarine cable service and press associations of the past generation, through their portraits and sketches of their careers as published in "Telegraphers of Today."

This work was issued in 1894 and includes biographical sketches of all the individuals connected with the interests mentioned at that period, many of whom have passed away from their earthly labors. The younger generation, however, will find much of interest in looking upon their portraits and reading of their achievements in life. Many of them are still alive and in harness, in the telegraph and other fields of activity.

This book, which is 11½ x 14 inches in size, was originally published at $5 per copy, but in order to close out the remaining copies we offer them at $1 per copy by express, charges collect.

Send orders to TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

Dry Cell Testing.*

BY W. B. PRITZ.

There are to-day at least 100 brands of dry cells upon the market, varying in quality from very efficient and reliable cells to those which must be considered very inefficient; and from these the consumer must select that brand which in his opinion will give best service. Before any conclusion can be reached regarding the adaptability of a cell to a particular service, the consumer must either accept the guarantee of the manufacturer or make for himself, as best he may, a service comparison of the cells in question.

The present diversity in the methods of testing cells is very troublesome for both the manufacturer and consumer. The former is often called upon to guarantee the service of his product when subjected to certain tests which have little or no relation to any which he may have adopted, and although it is not impossible, it does become quite difficult for a manufacturer of dry cells to calculate from the results of his regular tests just what may be expected of his product when subjected to a particular test required in the specifications of his customer. The adoption of some standard tests which would hold between manufacturer and consumer alike would, therefore, be very advantageous to both. The establishment of such tests and the publicity which would thereby be given to the whole subject of testing would decrease the tendency of the small consumers (who, taken collectively, must use a considerable percentage of the output) to place reliance in the so-called tests which now form the basis for their judgment of a brand of cell, such as amperage or voltage readings.

It is easily shown that there is in no sense a relationship between service and short-circuit current. It is true that the amperage reading of a cell, coupled with a familiarity with the particular brand, does serve as a good indication of the age of the cell or the presence of any serious defect; however, the customer who judges solely from the short-circuit current is very apt to obtain inferior quality, and yet we are informed by dealers that at least 90 per cent. of the customers who buy cells off the shelves demand that they be so read and in most cases select that brand giving the higher current.

Let us consider, then, the requirements of a satisfactory test for dry cells and the conditions which have the greater influence upon the results obtained. In general (other than for purposes of research) there are but two reasons for desiring a test upon dry cells: (1) To ascertain what life may be obtained from a brand of cells in a certain service; (2) to ascertain which one of several brands will give the longest life in that particular service.

With the former object in view the knowledge is best obtained by actual use of the cells in connection with the appliance. In some cases this is the only feasible way in which the definite information sought can be obtained. The great majority of tests are carried on, however, with the second object in view—viz., the comparison of two or more brands of cells for use in a particular service. Where the amount of testing is large, it is impossible, even were it expedient, to use the actual appliances for testing cells, and it becomes necessary to devise special testing methods and apparatus such that results obtained therefrom shall be comparable to the results obtained from the cells when placed in actual service. This is, we take it, the one necessary condition which dry cell tests must fulfil.

There have been tests devised which seek to go further and make the operating conditions not only comparable, but as similar as may be to the operating conditions of the service for which the test is intended. Upon this point there is some diversity of opinion. Some authorities claim that a test is of greater value and is more reliable the more nearly the conditions of test approach those of service, and, following out these claims, have devised certain tests which are rendered quite complicated, requiring much attention and apparatus for their continuance, by the introduction into the method of some of the irregularities to be expected in service. It is questionable, however, if results of greater meaning are obtained from such strict adherence to service conditions. At best, such a test is but an approach to actual service, which must be continually varying from time to time and from locality to locality. Again, the apparatus necessary to carry on an irregular, intermittent test is very complicated and requires much careful attention. This feature limits its use to the large consumers and manufacturers.

Questions are often asked regarding the advisability of testing various brands of cells by connecting them in series and discharging them simultaneously. In general, we would advise against this method, though there are occasions when it is the only one that can be employed. Especially is this true when test conditions, such as length of contact and recuperation periods, strength of current and temperature of the battery, cannot be held constant for the separate testing of various brands. It is much preferable, for instance, to use the series method of test upon an automobile than to test the various brands upon different machines or upon the same machine at different times.

Temperature is a most important factor in dry cell testing, and a large part of the non-uniformity in the results of tests may, we think, be traced to temperature variations. For instance, the current increases as the temperature rises, and the differences in the current obtainable increase considerably as the temperature falls. The influence of temperature upon service is greater than it is supposed. Tests show great variations are obtainable between 15 deg. and 35 deg., between which values practically all testing is done. This

*Abstract of a paper read before the American Electrochemical Society.

Digitized by Google

makes the importance of temperature regulation very evident. The effect of temperature also varies with the nature of the service, high temperatures giving longer service where the drain is heavy, while low temperatures are favorable for light drain service lasting over a considerable period. Of prime importance in dry cell testing is a knowledge of the effect of temperature upon the rate of deterioration of cells when left on open circuit. To determine just what this effect might be, a number of cells were stored at seven different temperatures. The following table gives the initial currents and the drop in amperage after ten weeks, expressed as a percentage of the initial values.

Temperature.	Initial amp.	Per cent. drop in amp. in 10 weeks.
5°C.	18.1	4.4
25°C.	22.0	10.0
35°C.	21.0	19.0
45°C.	22.8	25.0
55°C.	23.0	52.0
65°C.	20.5	71.0
75°C.	21.0	98.0

The greatly increased rate of deterioration on open circuit at high temperatures no doubt accounts for the poor service obtainable at such temperatures over long periods of time. A knowledge of this effect of temperature would undoubtedly explain the cases, which are at times brought to our attention, of cells rapidly deteriorating upon a dealer's shelves, from "no cause whatever." The cells should be stored in a dry, cool place, and not in the corner behind the stove.

In interpreting the results obtained from a test of various grades of cells a caution must be given against drawing definite conclusions from the outcome of a single or a small number of tests. When the matter of choosing a brand is of much importance it is necessary to run a series of tests over a period of six months or a year. In this way a very good idea may be obtained of the average service results which may be expected.

In regard to the terms in which the results of dry cell tests should be reported, there is some difference of opinion, some authorities contending that the ratings should be expressed as the number of ampere-hours given by a cell under specified conditions to a certain working voltage value. Others claim that more practical meaning is attached to a statement of the length of time during which the cell is able to maintain its working voltage above the specified limiting value. It is the author's opinion that that method of rating should be used which gives to the consumer the exact information which he desires, hence, the rating of cells by the length of service of a given kind which they are capable of giving is favored.

It is perfectly evident that the consumer is interested in the length of service which he is able to obtain from a battery and not in the amount of energy given. At first thought it might appear that the ampere-hour capacity of a dry cell bears such a relation to length of service, that either method of rating would give the same information. Such is not the case, however. Differences in discharge rate cause vast differences in the number of ampere-hours obtainable from the cell. From the nature of the discharge curve, it is quite difficult to calculate the length of service obtainable under the conditions limiting the ampere-hour rating, while to go further and deduce from the rated ampere-hour capacity under one set of conditions, the output to be expected under different conditions becomes a hopeless task. Equally hopeless is the final interpreting of the result in terms of length of service. Again, a dry cell does not always give length of service, which is proportional to ampere-hour output. It is easily possible to produce two dry cells which will give equal lengths of service the ampere-hour output of which will show marked differences. Hence a statement of the ampere-hour capacity of two brands of cells is very likely to be misleading, as it does not settle definitely which is the better cell to use upon a given service. For research purposes the energy or ampere-hour output of a cell is very useful, but as a practical rating for dry cells it is not satisfactory, especially from the standpoint of the consumer.

Wireless Telephony Through Water.

Exhaustive tests have recently been made by Mr. A. W. Sharman in England with instruments invented by him for telephoning through water without wires. The microphone used in speaking is connected in series with a battery of four or five dry cells and an impulse coil, the coil being of special construction and giving very short, induced currents of high potential, which are communicated to the water by two wires connected to the terminals of the coil and terminating in plates buried in the sand or submerged in the water. Two similar plates, connected direct with a very low-resistance telephone receiver, enable the speech to be "picked up" at distances of a mile and more.

The speech transmitted through the water has been very distinct, and the system has shown good possibilities for use as a means of verbal communication between two ships, such as a battleship and a submarine. The effect is very directional, and another advantage is that with a small tuned buzzer telegraphic signals can be transmitted through the earth or water for a distance of several miles. The primary energy required is extremely small, four watts sufficing to telephone over a distance of two miles.

Electrical Communication in Jamaica. — The telegraph system of Jamaica, which is operated by the Government, comprises 881 miles of line. There are also about 800 miles of telephone lines on the island, two submarine cable landings and one wireless station. Mr. Harry C. Wilson is superintendent of government telegraphs, with headquarters at Kingston.

Electric Waves Directed by Wires for Intercommunication Purposes.*

BY MAJOR GEORGE O. SQUIER.

During the past twelve years the achievements of wireless telegraphy have been truly marvelous. From an engineering viwpoint, the wonder of it all is, that, with the transmitting energy being radiated out over the surface of the earth in all directions, enough of this energy is delivered at a single point on the circumference of a circle, of which the transmitting antenna is approximately the center, to operate successfully suitable receiving devices by which the electromagnetic waves are translated into intelligence.

The "plant efficiency" for electrical energy in the best type of wireless stations yet produced is so low that there can be no comparison between it and the least efficient transmission of energy by conducting wires.

The limits of audibility, being physiological functions, are well known to vary considerably, but they may be taken to be in the neighborhood of sixteen complete cycles per second as the lower limit and 15,000 to 20,000 cycles per second as the upper limit. If, therefore, there are impressed upon a wire circuit for transmitting intelligence harmonic electromotive forces of frequencies between 0 and sixteen cycles per second, or, again, above 15,000 to 20,000 cycles per second it would seem certain that whatever effects such electric wave frequencies produced upon metallic lines, the present apparatus employed in operating them could not translate these effects into audible signals.

Within the past few years generators have been developed in the United States giving an output of two kilowatts and above at a frequency of 100,000 cycles per second, and also capable of being operated satisfactorily at as low a frequency as 20,000 cycles per second.

The necessary conditions for telephony by electric waves guided by wires are an uninterrupted source of sustained oscillations, and some form of receiving device which is quantitative in its action. In the experiments described in multiplex telephony it has been necessary and sufficient to combine the present engineering practice of wire telephony and telegraphy with the engineering practice of wireless telephony and telegraphy.

The frequencies involved in telephony over wires do not exceed 1800 to 2000, and for such frequencies the telephonic currents are fairly well distributed throughout the cross section of the conductor. As the frequency is increased the so-called "skin effect" becomes noticeable, and the energy is more and more transmitted in the ether surrounding the conductor.

At frequencies of 100,000 cycles on wire circuits the phenomena may be considered as a "super-skin effect" or "film effect," where the actual mass of the metal conductor involved is but a small fraction of the total. At such frequencies the flow of energy is controlled by reactances in the ether surrounding the conductor, rather than by the ohmic resistance of the wire as in battery telephony and telegraphy, and when these reactances are balanced at the receiving end of the circuit by the process of electrical "tuning" the one hundred thousand small packages of energy in the form of electromagnetic waves, which are delivered in each second of time at the receiving end of the circuit are thus added together to produce a cumulative effect many times greater than without such electrical tuning process. Extra etherial "channels" of intercommunication are by these means provided without the expense of erection and maintenance of special wires for the purpose.

Furthermore it has been found possible to superimpose, upon the ordinary telephonic wire circuits now commercially used, electric waves of ultra-sound frequencies without producing any harmful effects upon the operation of the existing telephonic service. Fortunately, therefore, the experiments described are constructive and additive, rather than destructive and supplantive.

Electric waves of ultra-sound frequencies are guided by means of wires of an existing commercial installation and are made the vehicle for the transmission of additional telephonic and telegraphic messages.

The source of electric waves used in the experiments described was a special type of dynamo, capable of producing 100,000 cycles per second and also capable of operating regularly at 20,000 cycles. This gave a wide range of frequencies for tests over an actual commercial telephone line of about 776 ohms resistance and capacity of .7 microfarad. The cable being lead covered throughout, it practically corresponded to a submarine cable about seven miles in length. The generator was of the inductor type and the rotor operated at a speed of 20,000 revolutions per minute or would roll as a wheel from the United States to Europe in four hours. The friction, or adhesion, of the air against the rotor was so great at this speed, as to require five kw. to overcome this alone, although the total output of the machine is but 2 kw.

Severe tests were described to determine the efficiency of a single wire with earth connection as a circuit for commercial telephony by high frequency methods, and these tests showed that such circuits are entirely practicable for this work, thus doing away with the necessity of constructing two wires for a telephone toll circuit as is now required.

Since the inductance and capacities required for this range of frequencies are a thousand times smaller than those employed in battery signalling, the complete and absolute separation of two independent telephonic conversations on the same pair of wires was readily obtained.

The transmission of energy at these ultra-audible frequencies was so radically different from

*Synopsis of paper read before the New York Electrical Society, October 27.

Digitized by Google

the phenomena at low frequencies by metallic conduction that the results very closely resembled pure radio-telegraphy. The energy waves were broken away from the source as from a transmitting antenna and thereafter had no perceptible reactive effect upon the source at the transmitting station. It was, therefore, not possible to tell from the transmitting station whether or not the distant end of the line was open or "shorted."

Since the loss of energy on the metallic "film" of the line in transmission is proportional to the square of the line current, it is permissible to put the energy in any form desirable for transmission and this is controlled by the ratio of transformation of the oscillation transformer at the transmitting station. With a ratio of but one to five excellent speech was obtained with a transmitting line current almost too small to be read on any commercial ammeter. In battery telephony this ratio is above 1 to 20, so that the line currents may be small and, therefore, line losses decreased inversely as the square.

The ringing circuit was operative both ways with no apparent effect on the high frequency telephone transmission. This ringing circuit developed a comparatively large alternating current flowing in the wire at about thirty cycles per second and at a voltage of many times that of either the high frequency or the battery side of the circuit.

Articulation tests, including music, numerals and other difficult combinations, gave satisfactory results, with no interference whatever between the two sides of the circuit.

By holding one telephone receiver to one ear and the other receiver to the other ear the receiving operator could hear two entirely different conversations simultaneously over the same pair of wires.

The distortion of speech, which is an inherent feature of telephony over wires, should be much less, if not practically absent, when we more and more withdraw the phenomena from the metal of the wire and confine them to a longitudinal strip of the ether which forms the region between the two wires of a metallic circuit.

The tuned electrical circuit at the receiving end readily admits electromagnetic waves of a certain definite frequency, and bars from entrance electromagnetic waves of other frequencies. This permits the possibility of utilizing a single circuit for multiplex telephony and telegraphy.

Investigating Business Methods.—The United States Senate Committee on Interstate and Foreign Commerce on November 15 began its investigation into modern business methods with a view to legislation for further trust control. The committee has plenary powers to conduct an investigation on the widest scope. Among the witnesses to appear will be Mr. Theo. N. Vail, president of the American Telephone and Telegraph Company and of the Western Union Telegraph Company.

Electric Club of New England.

Mr. C. F. Ames, district commercial superintendent of the Western Union Telegraph Company, Boston, Mass., made an address before the meeting of the Electric Club of New England which was held in Boston on November 10. His remarks were very entertaining and instructive, and he explained how since the new three-column arrangement of forces had been put into effect, every effort had been exerted by the commercial men of the district to increase the popularity of the telegraph service with the general public, by specializing the new types of service, such as the night and day letters, and the various methods which have been devised by the company's agents whereby customers have been shown how the new forms of service would be a positive benefit as order-getters. Great stress was laid on the value of politeness to customers by all telegraph employes, both by the clerical force, messenger boys and the telephone operators.

These points have always been emphasized by Mr. Ames and his staff, but only since the traffic and plant routine has been assumed by the other department heads has it been possible to vigorously follow up such lines of endeavor.

Mr. O. A. Conner, manager of the Boston district of the Western Union Company, also made a few remarks. He gave the club a vivid account of how difficult it is to obtain the actual hard cash from the public, that is, how hard it was to hold the present volume of business and get more. His remarks were very witty and optimistic, however, and he referred to the fine spirit of co-operation shown by the plant and traffic departments.

Other speakers were Mr. J. B. Rex, general traffic chief; Mr. J. A. Molloy, commercial manager of Boston branch offices, and Mr. J. A. Meldrum, cashier.

There were eighty persons present, this being the largest number in attendance at a meeting in the history of the Club, and attesting to the popularity of the subjects in hand and the speakers.

As was noted in these columns November 16, the Electric Club at this meeting voted to affiliate with the New England Telephone and Telegraph Society as an independent unit, to be called "The Western Union Chapter."

Dry Storage Battery.—A patent has been issued in England on a dry storage battery. The construction of the battery is briefly described as follows: The positive electrode is a carbon block of star-shaped cross-section, fitted into the center of a block of depolarizing material. The electrode is separated from a zinc electrode of square section by a series of cane strips ⅛ in. square to allow for air circulation. In charging the cell contact is made with the zinc through the moisture absorbed by the cane strips from the electrolyte. As the charging proceeds a spongy deposit collects on the zinc and makes a permanent porous connection between the zinc and the electrolyte.

New System of Wireless Telephony.

BY CHARLES PRONER, NEW YORK.

Mr. Samuel Wein, a young wireless experimenter of New York, has conducted some novel and original experiments in the line of wireless telephony. It is stated that in a recent test he transmitted speech wirelessly a distance of approximately twelve miles.

The accompanying diagram shows the electrical connections.

In his system of wireless telephony, Mr. Wein claims to have overcome the difficulty of adjusting the arc lamp. He has applied the same principle to the arc as is used in the quenched spark system, and calls his system the quenched arc system. By the quenching of the arc he has discovered that the electrodes require no cooling.

The negative and positive electrodes used in the arc are of a special metal that increases the wave length about twofold. Instead of using a hydrogen blast on the arc, Mr. Wein places a

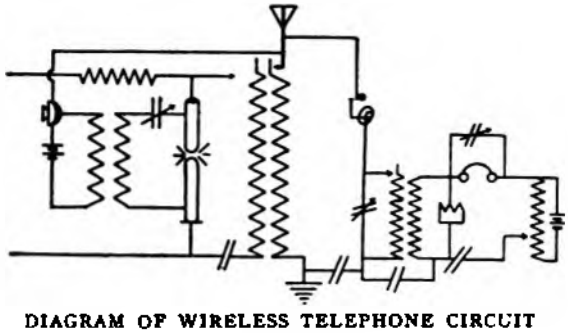

DIAGRAM OF WIRELESS TELEPHONE CIRCUIT CONNECTIONS.

spoonful of vaseline on each electrode; this being used in order to increase the frequencies of the arc.

The microphone employed in the experiment was tested and it is stated showed some remarkable results. It carried as high as 440 volts and 7 amperes on a closed circuit without burning or caking.

Contrary to the usual belief Mr. Wein finds that better results can be obtained by using hard metals firmly held between two pressure surfaces, as found in the carbon microphone. This microphone, it is stated, has been used successfully as a telephone relay with excellent results.

Patents are now pending on Mr. Wein's wireless telephone system.

Notes on Radio-Telegraphy.

The *Journal* of the Washington Academy of Sciences contains some notes from Mr. L. W. Austin of the United States Naval Wireless Telegraph Laboratory.

Wave Length and Ground Absorption of Electrical Waves.—Since the early days of wireless telegraphy, the country lying to the north and northeast of Newport, R. I., has been known to show a very large absorption for electrical waves.

During the experiments in long-distance radiotelegraphy carried on at Brant Rock, Mass., during the summer of 1910, the signals sent out by the "Birmingham," lying at Newport, were measured at Brant Rock, forty-five miles away. The wave-lengths used were 1,000 meters and 3,750 meters and the received signals were measured on a fifteen-ohm tellurium-constantine thermoelement. One millimeter on the thermoelement galvanometer corresponded to a current of 263 microamperes.

It was found that ninety-five per cent. of the energy was absorbed in the case of the 1,000-meter wave, while in the case of the 3,750-meter wave the ground absorption was not detectable, the observed signals being slightly stronger than the calculated values.

The experiment explains fully why with the short wave-lengths ordinarily used, wireless communication has been so difficult over this region and indicates that where such difficulties are encountered, longer wave-lengths should be employed.

Directive Action of the Marconi Bent Antenna at Clifden, Ireland.—While the directive action of the Marconi bent antenna at short distances has been amply demonstrated by Marconi, Fleming and others, it has not seemed certain that this radiation asymmetry would not diminish as the distance increased so that at great distances the radiation distribution would be the same as that of an ordinary antenna.

Recently at the request of the wireless laboratory, the National Electric Signaling Company made telephone shunt measurements on the signals received at its Brant Rock station from the Marconi transatlantic station at Clifden. These indicated an average received energy in the day time of 5×10^{-8} watts. I have been unable to obtain from the Marconi Company any data on the value of the antenna current at Clifden, but nevertheless some conclusions can be drawn from the information at hand. The distance from Clifden to Brant Rock is 2,640 nautical miles. The height of the Clifden antenna considered as a flat top is approximately 200 feet, the effective receiving height of the Brant Rock umbrella antenna was found in the recent long-distance experiments to be approximately 350 feet. The wave-length of Clifden is a little more than 6,000 meters and the total available power is 1,100 horsepower.

We may calculate that the sending antenna current was equal to 810 amperes, which is an enormous value. If the total antenna resistance is only one ohm, it corresponds to 660 kilowatts, which is more than the whole 1,100 horsepower would be able to transmit to the antenna. But this resistance is improbably small.

From this it must be concluded that unless the formula is grossly in error the bent Clifden antenna shows a decided directive effect even at this distance.

Desiccators.*

BY J. G. HINES.

At a recent meeting of the Institution of Post Office Electrical Engineers the engineer-in-chief stated that, excluding distribution cable, the length of paper-core cable already in use exceeded 2,300 miles, and that this mileage was being steadily increased.

In the type of cable referred to the insulation resistance depends entirely, and the electrostatic capacity to some extent, upon the hygrometric state of the air in the cable. The subject of desiccation is therefore one of considerable and increasing importance.

In the department's specifications for paper-core cable a minimum insulation resistance of 5,000 megohms per mile is specified, but, owing to the method of drying adopted at the manufacturers' works, the insulation resistance obtained is generally greatly above the minimum.

The method of drying paper-core cables at cable factories differs considerably from that employed to dry cables *in situ*, and is undoubtedly more efficient, but unfortunately it is not practicable to apply the factory method to cables which are in conduits.

Although there are differences of detail, the principle of drying cables is the same at all factories. After a cable has received the outer layer of wires it is wound upon an iron drum and placed in an oven heated by coils of steam pipes. The door of this oven is sealed to prevent the entrance of damp air. The air in the oven is then withdrawn by means of air pumps, and partly replaced by air which has first been dried by passing it through cylinders containing quicklime, calcium chloride and cotton-wool in the order named. The flow of air is restricted so that a vacuum of about 21 in. of mercury is maintained in the oven. The conditions inside the oven are thus favorable to the rapid evaporation of any water that may be in the cable, as the atmospheric pressure is very low, the temperature of the water and air is high, and the air is dry and is constantly being renewed.

The importance of the provision of the air inlet was not at first recognized, and a higher vacuum was then obtained, but it was found that, in the absence of air, heat was not readily conducted from the sides of the oven to the cable, and fresh layers of dry air were not brought into contact with the damp cable.

Occasionally cables are dried by the use of heat alone, but the operation takes longer, and is fraught with a certain amount of danger, as the paper is rendered brittle if overheated.

On account of the rapidity with which evaporation takes place at very low pressures, attempts have been made to apply a modification of the vacuum method to cables *in situ*. Of course it is not often possible to heat a cable throughout its whole length, but in one case it was possible to warm a considerable portion of a length and to admit warm, dry air in the inlet which was provided. Unfortunately there were other inlets which were not intentionally provided, and it is feared that while it is necessary to use cable-heads, pot-heads, etc., vacuum drying cannot be applied advantageously.

Up to the present the method generally adopted by the department has been to pump compressed air into the cables through a drying agent.

*Abstract from "The Post Office Electrical Engineer's Journal," London.

Improved Telephone System.

Mr. C. W. McKibben, superintendent of telegraph, Gulf Pipe Line Company, Beaumont, Tex., is the inventor of a telephone system, which he says has given excellent satisfaction for the past three years on a circuit nearly 500 miles long. He has been able to talk on a metallic circuit No. 8 iron wire for 400 miles with some ten to fifteen telephones across the line, the bells being of 2,000 ohms. This apparatus has been used satisfactorily on Bell telephone circuits, when the latter instruments would not work.

In Mr. McKibben's arrangement the receivers are cut out of circuit when the transmitter is in use, receivers of 1,400 ohms being used across the line. For this purpose he uses a little push button under the thumb. In talking, the button is pushed, and when receiving the pressure on the button is released.

A patent on this device was issued to Mr. McKibben September 26. The object of the invention is to provide an effective telephone set and circuits therefor for use in transmitting over a line of high impedance. In the operation of the invention he provides a system whereby both highly efficient transmitters and high power induction coils may be employed in conjunction with very sensitive receivers and yet without producing unpleasant effects in the ears of the person speaking into the instrument. To this end he provides for the interposition in the receiver branch of the circuit of an impedance device, and preferably disabling means for the impedance device, arranged in conjunction with means for potentiating the transmitting devices in such a way that when they are potentiated, the impedance device is likewise potentiated for operation; and vice versa.

Mr. McKibben states that he is using telegraphones embodying the same principle, and that they can out-talk and give better satisfaction than any instruments he has yet found. He uses standard apparatus, but arranged in a special manner. He claims to be able to operate his telegraphones on circuits that would have to be abandoned by the use of standard telegraphone equipment.

Modern Methods in Robbery.—The town of McComb, Okla., was raided recently by wise robbers. They first cut the telegraph and telephone wires, then blew open the safe in the town bank and got a large sum of money. The telegraph and telephone lines being cut an alarm could not be sent out so the robbers escaped.

Odd Causes of Wire Trouble.

In our issue for September 16 we published an amusing story by Mr. R. H. Tudor, manager of the Western Union Telegraph office at Chattanooga, Tenn., about the grounding of a wire in which a farmer's mules and a wire fence were concerned.

Mr. E. F. Rowe, of the Union Pacific Railway Company, Laramie, Wyo., tells of a case that fell within his experience when he was wire chief for the Chicago, Burlington and Quincy Railroad.

"A branch wire was burned in two during an electrical storm," he says, "and a section hand very kindly made temporary repairs by splicing it with a length of barbed wire. Being unable to stretch the wire enough to clear the weeds, he placed a forked stick under the splice to hold the wire up. His temporary forked pole would not stand up to suit him so he guyed it to the fence with another piece of barbed wire tieing it to the splice and fence wire. It made a good ground as it had been raining several days. The lineman thanked him kindly for his assistance, but we could never understand why he thought the weeds would bother the wire and the fence wire would not."

Lengthening of Telegraph Signals.

Mr. Béla Gati, manager of the Royal Hungarian telegraph and telephone experiment station, Budapest, Hungary, describes in *Electrotechnik und Maschinenbau* some experiments which were carried out for the purpose of determining whether the lengthening out of telegraph signals which occurs with direct current on long lines and cables would take place with alternating current. By connecting together various long-distance lines forming a loop, it was possible to have the sending and receiving ends in the same office, and by means of an oscillograph connected to the two ends of the circuit the duration of signals at the sending and receiving instruments could be recorded. It was found that with alternating current the duration was the same, no lengthening out of the signal being apparent. He consequently concludes that rapid telegraphy in ocean cables is quite possible where the self induction does not exceed 0.01 henry.

Mr. Edison's Historic Platinum Electrodes.—An interesting story is told by Mr. W. H. Meadowcroft, is his book "The Boy's Life of Edison,' of how Mr. Thomas A. Edison came into possession of some battery materials during his early career, including three platinum electrodes which are still in service.

"Edison" says Mr. Meadowcroft," was ever keenly anxious to add to his stock of experimental apparatus, as an incident of this period shows: 'While working at Stratford Junction, Ont.,' Mr. Edison says, "I was told by one of the freight conductors that in the freight-house at Goodrich there were several boxes of old broken-up batteries. I went there and found over eighty cells of the well-known Grove nitric-acid battery. The operator there, who was also agent, when asked by me if I could have the electrodes of each cell, which were made of sheet platinum gave his permission readily, thinking they were of tin. I removed them all, and they amounted to several ounces in weight. Platinum even in those days was very expensive, costing several dollars an ounce, and I owned only three small strips. I was overjoyed at this acquisition, and those very strips and the reworked scrap are used to this day in my laboratory, over forty years later.'"

Secretary Stanton and the Telegraph.

In the address of Mr. David Homer Bates of New York, which was read at the unveiling of the statue of secretary of war Edwin M. Stanton, at Steubenville, Ohio, September 7, are given some interesting facts regarding the secretary's interest in the telegraph prior to and during the civil war.

"Edwin M. Stanton," he said, "became interested in the Morse telegraph as early as 1847, three years after the opening of the experimental line between Washington and Baltimore. The telegraph had crossed the Alleghanies in 1846, the first message out of Pittsburg having been sent on December 29 of that year, advising President Polk of the departure of Pennsylvania troops for General Taylor's army in Mexico. To carry the telegraph west, the Pittsburg, Cincinnati and Louisville Telegraph Company was formed in September, 1847, and in the list of directors appear the names of two residents of Steubenville, Ohio, Edwin M. Stanton and Joseph Means.

"The United States Military Telegraph Corps," he continued, "was a special organization, under the immediate direction of the secretary of war. During the civil war the executive mansion was not, as now, connected by telegraph, and all the president's telegrams were handled at the War Department.

"The history of the civil war was largely recorded by telegraph, which branch of the service Stanton called his right arm."

Mr. Bates dwelt at length upon secretary Stanton's character as a man and as an official, and refers to the incident following the announcement of the capture of Richmond and Petersburg, when William E. Kettles, the operator who received the message, was held out of the window by Stanton so the crowd could see "the operator who received the news of Richmond's fall."

What's in a Name?—Mr. P. V. DeGraw, fourth assistant postmaster-general, Washington, D. C., was recently shown a telegram in which his name appeared, not as he spells it, however, but as "it came" by wire. The initials suffered somewhat and the name, after filtering through the magnets and the receivers' brain, became "See 64 De Graw."

INDUSTRIAL NEWS.

Western Electric Business.—Sales of the Western Electric Company for the ten months of the current year are about 3% ahead of last year, the foreign branch of the company's interest showing up somewhat better than domestic business. In the United States during October all sections except the Pacific Coast district showed decreases. The East has been the section of the country to show the greatest falling behind. Two more months of the company's year remain and it now seems fairly certain that the whole year's business will run very close to $66,000,000 which will make 1911 the second best year in the company's annals, being exceeded only by 1906, with sales of $69,000,000.

Improved Fuse Wire.

A bi-metal fuse wire was exhibited at the recent London electrical exhibition and attracted favorable comment. It is stated to be a noteworthy improvement in fuse wires. It consists in surrounding a small copper wire with a relatively large coating of alloy whose melting point is very much below that of copper. The wire will carry indefinitely 90 per cent. of its fusing current. Added to this sharpness of rating is the ability to carry six times the full-load current for short periods, as in starting motors. In addition to these qualities, the new wire has a property of "indicating" (by the melting of the outer alloy sheath) several seconds before "blowing"; furthermore, the use of a copper core makes the wire smaller and lighter for a given current rating, and thus, although higher in cost per pound, it is no more expensive per foot. This wire is called "Vanalium."

Current Gauge and Detector.—At the recent electrical exhibition in London was shown the Frisby mechanical electric current gauge and current detector. The first named resembles a pair of pliers; by closing it around a cable carrying a direct current and turning a knob the strength of current (in amperes) may be read on a scale. No cutting of the cable or removal of insulation is required. The current detector is based on a similar principle, but does not give a measure of the current strength in amperes. Instead, it shows the presence or absence of a current, and if a current is present the direction of flow may be determined. Among the American goods exhibited were Okonite and Manson insulating tapes, the Edison storage battery and the Edison business phonograph.

Manufacture of Electrical Apparatus, Etc.

A preliminary statement of the general results of the Thirteenth Census of establishments engaged in the manufacture of electrical machinery, apparatus and supplies has been issued by Director Durand of the Bureau of the Census, Department of Commerce and Labor, Washington, D. C. The manufacture includes dynamos and dynamotors, transformers, motors, storage and primary batteries, arc and incandescent lamps, searchlights, transmitters and receivers, rheostats and resistances, electric welding and therapeutic apparatus, electric switches, signals and attachments, and similar machinery, apparatus and supplies.

The general summary shows increases in all the items at the census of 1909 as compared with that for 1904. The number of establishments increased 29 per cent.; capital invested, 54 per cent.; the gross value of products, 57 per cent.; cost of materials, 62 per cent.; value added by manufacture, 52 per cent.; average number of wage earners employed during the year, 44 per cent.; amount paid for wages, 55 per cent.; number of salaried officials and clerks, 69 per cent.; amount paid in salaries, 82 per cent.; miscellaneous expenses, 32 per cent.; primary horsepower, 51 per cent.

There were 1,009 establishments engaged in this industry in 1909 and 784 in 1904, an increase of 29 per cent. The capital invested as reported in 1909 was $267,844,000, a gain of $93,778,000, or 54 per cent. over $174,066,000 in 1904. The average capital per establishment was approximately $265,000 in 1909 and $222,000 in 1904.

Entertainment of the New York Telegraphers' Aid Society.

The annual entertainment of the New York Telegraphers' Aid Society was held at the Lexington Avenue Opera House, New York, on the night of November 21, and was one of the most successful ever given by that organization. There were between 1500 and 2000 persons present and everyone had a most enjoyable time. The programme was arranged with excellent taste, and consisted of eight parts of vaudeville entertainment, which was of the highest class. At the conclusion of this part of the programme dancing was indulged in and the large floor presented an animated appearance with the scores of dancers moving about in time with the music.

Great credit is due to president Mr. R. J. Marrin for the success of the affair, and the support given to it by the many members of the fraternity by their presence was highly appreciated by the officers of the society. Mr. J. P. Clolery was chairman of the entertainment committee and he performed his exacting duties in a most satisfactory manner. Mr. J. F. King was floor director, and was assisted by Messrs. F J. Sheridan and W. J. Gomber. Mr. E. E. Brannin was chairman of the reception committee, being assisted by Messrs. J. F. E. Hopkins and W. C. Morris.

The managers of the affair have good reason to be proud of the success of this year's entertainment, and it is gratifying to note that the society is receiving very liberal moral and financial support from the telegraph fraternity in and about New York.

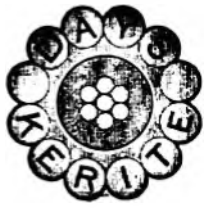
KERITE



INSULATED WIRES and CABLES

DEPENDABLE

Kerite Cables installed upward of 35 years ago, and exposed to deteriorating influences, are giving perfect service to-day.

EFFICIENT

Kerite does not rely upon the rubber in its composition for insulating efficiency. Kerite itself is a compound having superior insulating qualities.

SERVICE

A half century of successful service has demonstrated that Kerite possesses the essential qualities of safety, reliability and economy to an exceptional degree.

Kerite Insulated Wire and Cable Co.

The Railroad.

Removal of Headquarters.—The headquarters of Mr. F. T. Jennings, superintendent of the Canadian Pacific Railway Company's Telegraph, have been transferred from North Bay, Ont., to Sudbury, Ont.

Mr. C. J. Steinel has been appointed superintendent of telegraph of the San Pedro, Los Angeles and Salt Lake City Railroad, Los Angeles, Cal., vice Isaac T. Dyer, deceased. Mr. Steinel was Mr. Dyer's chief clerk and has had over twenty years' experience in the railroad telegraph service and is therefore well qualified to fill the position.

More Telephones for the Chicago and North-Western.—The Chicago and Northwestern Railroad has recently placed with the Western Electric Company an order for apparatus to be used in extending its telephone system of train control. A total of twenty-eight Western Electric type selectors are to be placed along the West Iowa Division, extending from Boone to Council Bluffs, Iowa, a distance of approximately 150 miles. The dispatcher will be located at Boone. Mr. William Bennett is superintendent of telegraph of the Northwestern.

Telephone Dispatching on Central of Georgia.—The Central of Georgia is another of the large railroad systems in the South to equip its lines with telephones for train dispatching, and to this end has placed an order with the Western Electric Company for equipment, including complete line construction material. The line to be equipped extends from Columbus, Ga., to East Thomas Yard, Birmingham, Ala., and is 160 miles in length. There will be located thirty-one way stations and fourteen siding sets, in addition to several telephone sets in the chief dispatcher's office.

Meeting of Railway Telegraph Superintendents.

A joint meeting of the eastern and western divisions of the Association of Railway Telegraph Superintendents was held in the general office assembly room of the Chicago and Northwestern Railway, Chicago, November 23 and 24.

The first day's session was called to order by Mr. C. Selden, superintendent of telegraph, Baltimore and Ohio Railroad, Baltimore, Md., who was afterwards chosen permanent chairman of the joint meeting.

The election of officers resulted as follows: Western Division—Mr. E. A. Chenery, Missouri Pacific Railway, St. Louis, chairman; Mr. W. F. Bentley, secretary. Eastern Division—Mr. Charles Selden, Baltimore and Ohio, Baltimore, chairman; Mr. B. H. Anderson, secretary.

The retention in files of all telegrams as per order of the Interstate Commerce Commission was a subject given general discussion, but no definite plan was evolved whereby the files could be relieved of the burden. It was finally decided that any concerted action by the association should be held in abeyance, since it developed that the Western Union Telegraph Company has already taken the matter up with the Interstate Commerce Commission and that the final ruling in its case would undoubtedly cover and govern that of the railroads.

The handling of Western Union reports between railroad offices and the superintendents of telegraph, by railway mail, which practice has been objected to by the post office department was next taken up and the discussion of this subject occupied the remainder of the time of the first day's session.

Several legal opinions were submitted but the question presented so many points which might be differently construed, that the whole matter was finally dropped and left to the discretion of the individuals interested, until such time as the Postmaster-General took action, it being understood that a decision by him is now pending.

After lunch the members were guests of the Kellogg Switchboard and Supply Company and were taken to its plant in automobiles.

At the second day's session Mr. E. A. Chenery occupied the chair.

A voluminous amount of data was presented pertaining to the information requested regarding the cost of maintenance, rates of pay, statistics, etc., in train movement service, since the adoption of the telephone, but owing to the absence of any uniform system of compiling the information, and the fact that none of the members present appeared to be in position to present anything considered reliable, the whole question was referred to a special committee, appointed by the chair, consisting of Messrs. U. J. Fry, Milwaukee, Wis., chairman; W. W. Ryder, Chicago, and W. F. Williams, Portsmouth, Va.

This committee is to gather and compile such statistics as it is able to obtain and report at the next annual meeting.

After a vote of thanks for the courtesies extended by the Chicago and Northwestern Railway, the Kellogg Switchboard and Supply Company and the associate members, the meeting adjourned and proceeded in a body in a private car on the Burlington to the plant of the Western Electric Company, at Hawthorne, whose guests they were at luncheon.

The attendance was as follows: Active members—Wm. Bennett, Chicago and Northwestern, Chicago; C. W. Bradley, Chesapeake and Ohio, Richmond, Va.; W. J. Camp and wife, Canadian Pacific, Montreal, Can.; G. A. Cellar, Pennsylvania Lines west of Pittsburgh, Pittsburgh, Pa.; E. A. Chenery, Missouri Pacific, St. Louis, Mo.; J. P. Church, Wabash, Decatur, Ill.; M. H. Clapp, Northern Pacific, St. Paul, Minn.; W. P. Cline, Atlantic Coast Line, Wilmington, N. C.; W. L. Connelly, Chicago, Indiana and Southern, Gibson, Ind.; E. E. Dildine, Northern Pacific, St. Paul, Minn.; G. A. Dornberg, Pennsylvania Lines west of Pittsburgh, Pittsburgh, Pa.; P. W. Drew, Milwaukee, St. Paul and Sault Ste. Marie, Chicago;

The Turner Monument Fund.

The contributions received up to date toward the Turner monument fund are as follows: Previously acknowledged, 1,706.99; A. B. Chandler, Brooklyn, N. Y., $10. Total, $1,716.99.

Mr. J. B. Taltavall, 253 Broadway, New York, is the treasurer of the fund, and all contributions are acknowledged in the columns of TELEGRAPH AND TELEPHONE AGE.

The monument which is to be located at Harriman (formerly Turner), N. Y., is now being cut under the supervision of Mr. Charles T. Ford, of Central Valley, N. Y., superintendent of the Harriman estate, and it is expected that the unveiling ceremonies will be held in December.

Our Subscription Contest.

Subscriptions under the contest rules are coming in rapidly and, apart from the immediate advantage derived, the results show what can be done with a little effort, and how wide the undeveloped field is.

The terms of the contest were given in our issue for September 1. Five prizes, amounting to $100, are offered those of our regularly appointed agents who send in the largest number of new subscriptions during September, October and November and up to December 21. The prizes are as follows: First, $50; second, $25; third, $15, and the fourth and fifth, $5 each. The contest is limited to new subscriptions and renewals only. The total amount of cash received from each agent on this account will decide the contest and in the event of a tie on any one prize, the prize will be divided.

Money must accompany all orders for subscriptions. Many of our agents secure subscriptions or renewals for from two to ten years. In cases like this a five or ten years' subscription will count as five or ten yearly subscribers, as the case may be.

Those at points where we have no agents will find it to their advantage to secure an agency appointment to canvass their section and participate in this contest. Many subscribers can be secured in this way, and the active canvasser in a small town will find as great an opportunity to win a prize as will a regular agent in a large city.

This is an excellent chance for agents to earn a substantial amount of money not only by capturing a prize, but also from the usual commissions earned from the subscriptions sent in.

Operator to Signal Foreman Through I. C. S. Training

W. C. Johnson, Box 708, Hudson, Wis., writes to the International Correspondence Schools as follows:

"I have the highest opinion of the I. C. S. system of instruction. When I enrolled for the Course I was working as a telegraph operator. The Course has been a great benefit to me in that it has fitted me for a better position and a higher salary.

"I am now Signal Foreman for the C., St. P., M. & O., with headquarters at this place. My salary has been increased 250 per cent, with full expense allowance."

This is the history of not only one, but thousands of I. C. S. students. All over the world men can be found who have made I. C. S. Courses mean progress equal to or even greater than Mr. Johnson's.

If you would like to secure a better position, investigate this salary-raising institution. Write today for information about any line of work you may wish to follow.

Obituary.

J. C. Fuller, the inventor of the Fuller bichromate battery, died in England recently. He was born in Bristol, in 1821.

George S. Duncan, aged 75 years, who carried messages with Mr. Andrew Carnegie in Pittsburg, Pa., died in Cuyahoga Falls, Ohio, on November 6.

Mrs. Harriet Pease Crapser, an operator for a Wall Street firm in New York, died in Brooklyn, on November 17. She was the daughter of Wilbur Pease, an old time telegrapher.

E. Monroe Cobb, of the Houston, Tex., office of the Western Union Telegraph Company, died at that place on November 15. He was in the service of the company for fifteen years, going to Houston from Atlanta, Ga., in 1900. He was a loyal and conscientious employe and generous and true to his fellowmen.

George Merrihew, aged 70 years, an old time telegrapher and a brother of Mr. James Merrihew, former superintendent of the Southern Division of the Western Union Telegraph Company, died in Philadelphia November 14. He was an attendant at the recent reunion of old time telegraphers at Atlantic City, N. J. He was identified with the telegraph in Philadelphia during his entire business career.

Georges D'Infreville, aged 65 years, a well-known electrician of New York, died in this city November 17. He entered the service of the Western Union Telegraph Company in 1872 and was for several years an electrical engineer of the company. Deceased was born in France and was prominent in telegraph circles until about 20 years ago, when he entered other business. He was an inventor of some note, one of his inventions being the wasteless battery zinc, which is so extensively used in gravity batteries. He was also the inventor of the duplex system of telegraphy bearing his name.

The Associated Press.

Mr. Paul Joyner has been appointed night chief operator of the Associated Press at Louisville, Ky.

The November issue of the "Service Bulletin of the Associated Press" contains an illustration of the new operating and editorial room of the Kansas City, Mo., "Star." The quarters are complete in their appointments, and the telegraph instruments are in close proximity to the editors.

Radio-Telegraphy.

International Wireless Conference.—The Bureau International de l'Union Telegraphique has announced that the next Radio-Telegraphic Conference will meet in London on June 4, 1912.

Wireless in Sweden.—A wireless coast station has been established at Gothenburg, Sweden, on the German system, for public service. It has a range by day of 1,200 km. (745 miles) and by night of 2,000 km. (1,240 miles). The tariff is 14 cents per word, and the lowest charge for a telegram is 1.40 fr. (28 cents).

Long Distance Wireless Transmission.—A wireless message was received at the Glace Bay, N. S., station of the Marconi Wireless Company, direct from Coltano, Italy, on November 19. This is the first message received direct from the new Italian station and it traversed a distance of about 4,000 miles.

Wireless at Massachusetts Institute of Technology.—A wireless station is being fitted up at the Massachusetts Institute of Technology, Boston, by the Wireless Society of that school. A 10-kw. transformer will be a part of a powerful sending station, by which the young engineers will be able to communicate with many other eastern colleges as well as regular stations. Prof. Harold Pender, of the department of electrical engineering, is aiding the society in the design of the station.

Wireless Messages from the Crippled "Olympic."—From the time when the steamer "Olympic" was run into a few months ago by the British cruiser "Hawke," until her arrival at Southampton, the Marconi wireless installation on board was constantly utilized for sending messages from the vessel to destinations in all parts of the world. Within about an hour nearly 150 messages were dispatched from passengers on the "Olympic." These messages passed through the wireless station at Niton, Isle of Wight.

Telegraph and Telephone Extension in Norway.—The Norwegian Storthing has voted appropriations for the extension of the telegraph system, for telephone construction and for wireless stations at Bergen and Hammerfest and on Spitzbergen.

"World Movers."—Mr. Andrew Carnegie gives a list of the names of twenty-one "world movers" which includes Dr. Alexander Graham Bell, Thomas A. Edison, Benjamin Franklin and Sir William Siemens, of Siemens and Halske, Berlin, Germany, He modestly omits his own name from the list.

Mr. Harman D. Jones, of the Western Union Telegraph Company, San Francisco, Cal., in renewing his subscription writes: "Thanks for anticipating my desire to renew subscription. It would be real deprivation to miss even one number and I hope my sense of appreciation may be gratified semi-monthly by this welcome visitor for as many years in the future as it has been in the past."

The standard quadruplex of the Western Union Telegraph Company was described by Mr. William Finn and illustrated in our issue for November 1, 1910, and in our issues for March 16 and April 1, this year, was printed the official illustrated description prepared in the office of the engineer of equipment. Copies of these issues may be obtained at the office of TELEGRAPH AND TELEPHONE AGE at 10 cents each.

Understand What You Have to Do.

The following article by Mr. Theo. N. Vail president of the American Telephone and Telegraph Company and the Western Union Telegraph Company was published in a recent number of *Business Magazine.*

Understand what you have to do— and do it, is the principle that I might designate as the eleventh commandment in business. It is the keynote from which either harmony or chaos may come.

When a man understands a thing the consummation of it is half accomplished. For he goes forth with knowledge. Knowledge is power. He has studied all sides of the proposition, and is able to cope with and overcome difficulties as they present themeslves. He is rarely surprised. He knows what to expect either for or against him.

One of the prime factors in producing failure is this thing of being taken unawares with a point of procedure that was left to chance, and the understanding of it not thoroughly attained. Thus the other man who has studied the thing more fully has the advantage that you lack. There is not much in chance.

Occasionally a decision of chance brings the desired result. But it is precarious—unsafe. If there is a doubt in the business mind as to the understanding of a transaction, it were better, even at a loss, to get the information that will make the matter clear. If a man realizes and has understood conditions, even though he meets with reverses, it strengthens him for future action. He is not governed by self-reproach as to miscalculations.

Times without number we hear the complaint, "If I had only looked into it more closely." Often things look smooth and placid on the surface, and a hasty decision is made accordingly. And not until you have set sail do you realize the turbulent undercurrent which investigation might have disclosed.

It seems to me that there is the secret of success or failure—this thing of not only looking before one leaps, but looking thoroughly before so doing.

The man who is equipped with a sense of analysis and who can rightly measure the strength and weakness of the business at hand has the foremost faculty even in case of prospective defeat; he can most often, with a little effort, make it measure up to his deduction. For his understanding creates a sense of security that makes him invulnerable in withstanding the whims of disaster. Frequently an unheralded influence not reckoned with, a slight technicality overlooked—elements that should have been taken into consideration, —have been the cost of mistakes.

We do not despair of the mistakes made with seeing eyes, since we have gone into our project with full strength and willingness to abide by the consequences. But when we leave results to take care of themselves through laxity of understanding, they take care of themselves accordingly, and leave you to the greater care later.

It sums itself up, perhaps, in the "stop, look and listen" of the railroad crossing, which is the signal for going forward.

Thus the man who understands his work, and works understandingly, is he who creates the backbone of real endeavor.

The Continental Code in Wireless.—The question has been frequently asked whether it is necessary to know the Continental code in taking examinations for the position of wireless operator on ocean passenger steamers. On this point the regulations issued by the Bureau of Navigation, Department of Commerce and Labor, Washington, D. C., reads: "To secure a certificate an operator will pass an examination in the adjustment of apparatus, correction of faults, change from one wave length to another, transmission and sound reading at a speed of not less than fifteen words a minute American Morse, or twelve words Continental, as the operator may elect. Operators are advised to learn as soon as practicable the Continental system, recognized by the Berlin Convention and employed by the United States Navy."

From this it does not appear that a knowledge of the Continental code is necessary to pass an examination, but inasmuch as it is in extensive use any one qualifying as an operator should and is expected to familiarize himself with it as quickly as possible.

Radio-Telephone Promoter Arrested. — James Dunlop Smith, formerly president of the Radio Telephone Company, New York, was arrested on November 18, charged with having used the United States mails to defraud. The Radio Telephone Company was organized ostensibly to promote the use of wireless telephones, but, it is stated, almost its entire activity was devoted to the selling of stock. The complaint was brought by a woman in Camden, N. J., who was induced by Smith to buy Radio stock.

An Old Timer Retired.

Mr. Francis Ail McMullan, of Greenville, Ala., former manager of the Western Union office at that place, held the position continuously from November 1, 1868, until May 16, 1911, when he retired. Mr. McMullan was born in 1847 and entered the telegraph service in Greenville, January 1, 1862. During the Civil War he was railroad and military operator at various places in Alabama. At the close of the war he was employed by the Federal authorities as operator at Pollard, Ala.

Many subscribers find some one special article in TELEGRAPH AND TELEPHONE AGE alone worth more to them than the subscription price of the paper which is $2 per year.

Digitized by Google

The Electrophone.—Mr. Walter P. Phillips, the well-known old time telegrapher and formerly general manager of the United Press, New York, has printed in pamphlet form his address delivered in Bridgeport, Conn., recently in describing the Electrophone. The pamphlet includes some added matter taken from Mr. Phillips' writings, and a page of portraits of Mr. P. B. Delany, Mr. Phillips and Mr. Thomas A. Edison.

T. M. B. A. Assessment.—Assessment No. 532 has been levied by the Telegraphers' Mutual Benefit Association to meet the claims arising from the deaths of Freeman P. Johnson at Clarkston, Ga.; William D. Sargent at Somerset, Pa.; John A. Kelly at New Orleans, La.; George W. Hughes at Wilmington, N. C.

Special Meeting of Serial Building Loan and Savings Institution.—A special meeting of the shareholders of the Serial Building Loan and Savings Institution will be held in the office of the association, at 195 Broadway, New York, at 5.15 o'clock p. m., December 20, for the purpose of considering and passing a complete revision of the by-laws, rendered necessary by the changes made in the New York State banking laws, under which the Serial Association is conducted. The new by-laws have received the approval of the superintendent of banks, and a copy of the same is being sent to the members by Secretary Edwin F. Howell.

LETTERS FROM OUR AGENTS.

PHILADELPHIA, POSTAL.

District foreman J. R. Gorsuch was in New York recently on business connected with the service.

Mr. H. L. Bernstein has been transferred to the main office from the Bourse office.

Assistant wire chief F. P. McElroy has resumed his duties after an extended honeymoon through the west. Mr. and Mrs. McElroy were pleasantly surprised on their return to their new home by being presented with a handsome reclining chair, a gift of Mr. McElroy's office associates.

Mr. Lloyd E. Olmsted has been appointed printer attendant.

New arrivals: Messrs. Thomas Balkin, W. B. Ray, F. K. Holtzinger and J. L. Flynn.

PHILADELPHIA, WESTERN UNION.

The funeral of George Merrihew, who died in this city on November 13 and was buried on November 16, was attended by a large number of the fraternity of Philadelphia and New York including former general superintendent Mr. James Merrihew and Mrs. Merrihew, general superintendent A. G. Saylor and Mr. Elgin B. Saylor, of New York, and a delegation from Washington. Deceased was greatly beloved by all with whom he was associated and was always ready to extend a helping hand.

Mr. Harry V. Emanuel was sent to New Haven, Conn., to report the foot ball game between Princeton and Yale, as he is an expert at that kind of work as well as baseball.

CHICAGO, WESTERN UNION.

Mr. H. S. Worcester, of the Erie Railroad dispatcher's office at Huntington, Ind., was a recent visitor here.

Life Insurance is based upon the certainty of death at some time and its possibility at any time. The splendid financial position of the Telegraphers' Mutual Benefit Association, 195 Broadway, New York, is shown in the Reserve Fund, of $327,000, which, apart from current assets, amounts to nearly 6½% of the total contingent mortuary liabilities, and yields an annual revenue of more than $15,000. Operating on sound and correct principles, with ample security, it offers to the telegraph and telephone employe the best and most economical form of protection for the family and dependents yet devised. Write for particulars.

OFFICE MANAGEMENT

Report writing—handling of telegraph office accounts—relation of the operator to the public—penmanship—Lectures and practical work.

A new course designed to prepare telegraph operators for advancement—a thorough course by leading experts.

Booklet "H" to any address.

EAST SIDE Y. M. C. A. TELEGRAPH SCHOOL
New York City

An Interesting Letter.—Mr. A. L. Suesman, of Oak Bluffs, Mass., has facsimiles of an interesting letter from General Thomas T. Eckert to Fred Catlin. A copy may be obtained by sending four cents in stamps to Mr. Suesman.

TRANSMITTING MACHINES

I am placing on the market improved YETMAN TRANSMITTING TYPEWRITERS, and KEYBOARD TRANSMITTERS without typewriting features. Am prepared to exchange, repair or rebuild all old machines. Write for catalogues and particulars to

James Uncles, NORTH ADAMS Massachusetts

Rubber Telegraph Key Knobs.

No operator who has had to use a hard key knob continuously should fail to possess one of these flexible rubber key caps, which fits snugly over the hard rubber key knob, forming an air cushion. They render the touch smooth and the manipulation of the key much easier. Price, fifteen cents.

J. B. Taltavall, TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

The great telegraphic song hit,
"SEND ME A NIGHT LETTER, DEARIE."
Good, catchy music; beautiful title design magnificently printed in colors. Title contains night letter. Sung all over New York. 17c. by mail. All popular music sent by mail.
B. L. BRANNAN,
195 B'way, N. Y.

SOME POINTS ON ELECTRICITY.

BY WILLIS H. JONES.

Twice Told Tales.

In practical life one frequently encounters situations which apparently contradict the rules and laws given in the text books. This is naturally more or less perplexing., but in the end they are the best possible means of giving one a better understanding of the subject involved. The perplexity, however, is due to what is called a superficial education, that is to say a general knowledge of a subject but no thorough knowledge of any part of it. Were it not for these little difficulties these self-styled electricians would never discover how little they really know.

The trouble with too many of us is we are inclined to swallow a rule whole and either skip or ignore the qualifications entirely. The qualifications, after all, are what really give us the true inwardness of a rule or law, but it is not until we begin to put our superficial knowldege to practical test that we usually discover this fact.

For illustration, let us take the subject of ground wires. The unqualified rule states that if a conductor is grounded no current can pass at that point, yet owing to the manner in which the ground connection is sometimes made, some current often does get by, and that is the case when the ground wire possesses an appreciable amount of resistance.

An old lineman who had for years done good service removing crosses and grounds from external circuits, was called upon to assist in the wiring of a terminal switchboard in one of the large telegraph offices and while he had a fair knowledge of circuits, was greatly perplexed concerning the manner in which the one main line battery lead provided current for so many wires. After the connections were all made he remarked. "But what puzzles me is how the current gets by all those ground wires," referring to the lead running across the top of the board to which battery taps are connected to provide current for the various conductors, which, of course, terminate in a ground or grounded battery at the distant end. He knew from actual experience that when he was sent out to locate and remove a "ground" from a line conductor he could feel no current after he passed the fault, yet here was a wire clear across the board actually grounded in a hundred places by the wires it fed and current flowing right past each tap without the slightest interference.

The qualification of the rule concerning ground wires of which he was ignorant is, that although current cannot pass the point where the conductor comes in actual contact with a good "ground" or earth, it can and will flow beyond it if there is any appreciable resistance between the point where the conductor is tapped and the earth proper, such for instance, as when another wire falls across the conductor and one end of it lies on dry sandy, or other high resistance soil.

The reason is that current will flow into any side conductor that is grounded, provided the voltage at the point of contact has not fallen to zero, and it cannot reach zero until the earth itself is actually reached. The greater the resistance in the ground wire the greater the E.M.F. at the point of contact.

In the case of the feed or battery wire running across the top of the main line board, the conditions are different from a closed main line wire which may become dead grounded, but the principle is the same.

The E.M.F. which feeds this battery conductor is not allowed to drop in value when a grounded main line wire is connected to it, hence all such conductors get the benefit of practically its full value. This is brought about by leaving the distant terminal of the battery wire open. Under these conditions, the feed wire possesses an infinite resistance to current between the open end and the earth as nothing but the high resistance atmosphere completes the circuit.

The grounded main line conductors, although

Digitized by Google

of high resistance, offer comparatively no resistance to that of the "open end" air conductor, hence the E.M.F. is practically of the same value throughout the entire length of the battery wire.

This demonstrates the importance of having good ground wires at way stations, especially on long railroad circuits. A high resistance ground wire will often permit sufficient current to pass to enable stations beyond to hear the signals although they cannot "break." Trouble of this kind creates what is called an "escape."

Another illustration of the benefit derived from hearing or reading a statement of facts differently worded may be shown as follows. "A" asks "B" what constitutes a line balance on a multiplex circuit?

"A" replies. A balance will have been obtained when the same current flows equally through both the main and the artificial lines. He then asks "C" the same question. "C" replies, a balance will have been obtained when the total amperage in the artificial line coil of the relay is identical with that in the main line coil.

Now both of these replies are correct provided the relay coils are evenly wound, or, more properly speaking, have the same number of convolutions of wire in the coils. But "A" took it for granted that that was understood. "C" however, gives answer that requires no qualification and at the same time brings out the real interpretation of a true balance, viz., the creation of identical value of magnetic energy in each coil.

The distinction noted between the two replies corrects, or rather, amplifies the first impression made by "A's" reply, and at the same time leads to other useful information which plays a large part in connection with the operation of balancing, viz.: the perfection or imperfection of the coil windings in relays.

These two illustrations should readily convince the reader that the twice-or-thrice-told story method of studying explains the rapid progress some scholars make. The latter are continually running right into valuable nuggets of information without even looking for them and by the time they actually reach the different subjects in their natural sequence they are half prepared for the lesson and grasp the details in almost one reading. In this way study becomes both easy and a pleasure.

Cumberland Telephone Bond Issue.—The Cumberland Telephone & Telegraph Company will, on January 1, issue $15,000,000 in bonds in exchange for the minority stock of the company. The bonds will run 25 years.

Personal.

Mr. Thomas A. Edison visited Washington recently. He called at the White House where he met President Taft for the first time.

Mr. S. H. Flagler, manager of the telegraph department of the Standard Oil Company, 26 Broadway, New York, is confined to his home with typhoid fever.

Mr. Stephen E. Barton, a former telegrapher and now in the insurance business in Boston, was in New York recently on business and made personal calls on many of his old friends in the telegraph service.

Messrs. K. Y. A. Tong and K. C. G. Tong, sons of the director of the Imperial Chinese Telegraphs, arrived in New York recently on their way to China. They are attending school in England, and look more like Englishmen than they do Chinese.

Mr. E. H. Johnson, a former telegrapher and a well known pioneer in electric lighting made an address at the annual dinner of the Capt. John Ericsson Memorial Society of Swedish Engineers in New York, November 25. He told of the early days of electrical engineering and his business and personal relations with Mr. Thomas A. Edison.

Mr. V. L. Van Horne, of Auburn, N. Y., has been designated by the vice-president of the United States to succeed Mr. Charles Newsom as official telegrapher of the United States Senate, Washington, D. C. Mr. Newsom has resigned to enter the employ of the Western Union Telegraph Company at Indianapolis, Ind.

Mr. J. K. Butler, well known in telephone circles in New England and an old time telegrapher, has gone to spend the winter in Florida where he has an orange plantation. Mr. Butler has just rounded out fifty years of telegraph and telephone service. He is a well-known member of the profession being a constant attendant at Old Time Telegraphers conventions and was present at the recent Pioneer Telephone Convention in Boston.

Postal Telegraph-Cable Company.

EXECUTIVE OFFICES.

Mr. Minor M. Davis, electrical engineer of this company, has been appointed to be chief engineer of telephones of the company in addition to his present position. The position of chief engineer of telephones is a newly created one.

Mr. C. E. Bagley, district superintendent, Philadelphia, Pa., was a recent executive office visitor.

Mr. John B. Whittaker has been appointed manager of the Cumberland, Md., office, vice W. G. Morris, resigned. Mr. Whittaker was for several years connected with the telegraph department of the Cumberland and Pennsylvania Railroad.

The office at Fifth Avenue and Forty-second Street, New York, which was recently destroyed by fire, has been reestablished. It is fittted up in a very attractive manner and is modern throughout.

An evening class for the teaching of telegraphy to messengers has been established in the messenger department at headquarters at New York. Five operating tables with up-to-date equipment have been provided for the purpose and a competent teacher employed.

This company has fitted up a handsome and modern office at Holyoke, Mass.

This company has secured a new location for its Newark, N. J., office in the Union Building, a new and modern fireproof structure on Clinton Street, just off Broad. Handsome quarters will be fittted up and every convenience and improvement provided. The main office will be on the ground floor, and in the basement there will be shower baths, uniform room, etc., for the messengers. The old quarters at the corner of Broad and Market Streets have been inadequate for the company's needs for some time, and they will be given up reluctantly as the company has been located in the same building for many years. The new quarters, however, will be far superior in every way and are in the heart of the Newark financial district. Mr. John F. Coogan is the manager.

Joint Use of Poles.—Judge Dayton in the United States circuit court for the Northern district of West Virginia, has authorized the receivers of the National Telephone Corporation to enter into a contract with the Postal Telegraph-Cable Company for the joint use of poles and wires.

Minor M. Davis Appointed Chief Engineer of Telephones, Postal Telegraph-Cable Company.

Mr. Minor M. Davis, electrical engineer and chief engineer of telephones, Postal Telegraph-Cable Company, New York, was born at North Chatham, Mass., and attended school on the Island of Nantucket until he was 14 years of age. His first telegraph work was as a messenger in the Western Union Telegraph office in Nebraska City, Neb. After a year in that office, during which time he learned to operate, he went to Washington, D. C., where he soon found employment in a branch office of the Atlantic and Pacific Telegraph Company, in the Washington Hotel. After working in several other branch offices, he finally got a position as operator on the night force at the main office. The wires were leaky and very hard to work in wet weather, and continuous duty until the day force came around was not unusual. There was no extra. When young Davis took the position he was pleasantly but firmly told by the night manager that his hours would be "from five p. m. until h— freezes over, if necessary."

Mr. Davis worked for the Atlantic and Pacific, Western Union, Automatic, and Philadelphia and

MINOR M. DAVIS,
Electrical Engineer and Chief Engineer of Telephones, Postal Telegraph-Cable Company, New York.

Reading companies in Washington, Baltimore and Philadelphia. In 1878 he came to New York to be a substitute at the Western Union main office for another operator who had three months' leave of absence. When Mr. Davis left the Western Union service he was a traffic chief, giving much of his time to the study of the switchboard and the quadruplex and duplex. In 1883 he joined Mr. William Maver in writing "The Quadruplex;" a book still much used. In 1884 Mr. Davis was employed as assistant to electrician F. W. Jones of the Bankers' and Merchants' Telegraph Company. When the Postal Telegraph-Cable Company absorbed the Bankers' and Merchants', Mr. Davis, was retained in the electrical department, where he remained until January, 1898, when he became traffic manager of the Postal Company. He organized the traffic de-

Digitized by Google

partment and remained at its head until June, 1907, when he became electrical engineer of the company.

During his long service in the engineering department of the Postal Telegraph-Cable Company, Mr. Davis has given much attention to the use of telephones for local and long distance purposes.

Western Union Telegraph Company.

EXECUTIVE OFFICES.

Mr. Theo. N. Vail, president of the American Telephone and Telegraph Company and of the Western Union Telegraph Company, was the guest of honor at a luncheon given in San Francisco, Cal., recently by Mr. Henry T. Scott, president of the Pacific Telephone & Telegraph Company.

Mr. Belvidere Brooks, general manager, has issued a general order on the subject of office economies in the smaller things. Among them he enumerates discontinuance of unnecessary reports, records, etc., elimination of formality in much of the official correspondence; reduction of postage expense by consolidation of mail matter; reduction of electric light and gas bills; saving of drinking water, etc.

Mr. Thomas W. Carroll, assistant to the general manager, is in the South on a trip of inspection.

The office of Mr. W. N. Fashbaugh, traffic engineer, New York, has been removed from the fifth to the second floor.

Wm. Pitt Phelps, aged 70 years, who was identified with the electrical engineers' office of this company, died at his home in Merchantville, N. J., November 28. He was a brother of the late George M. Phelps, inventor of the printing telegraph and stock ticker, known under his name. Deceased was also an inventor of stock tickers.

Mr. C. H. Murphy, general superintendent of time service, New York, has returned from an extensive trip throughout the South, including Texas, in the interest of the time service which under his management has been developed to very large proportions during the past few years.

Mr. A. Woodle, district commercial manager, Syracuse, N. Y., has been transferred to the office of the general superintendent at New York for special service.

Mr. D. C. Dawson, district traffic superintendent, St. John, N. B., has gone to the Pacific Coast where he will spend three or four months resting. Mr. Dawson has not had a vacation for forty years.

Mr. H. J. Kinnucan, district commercial superintendent, Detroit, Mich., was in New York recently on company business.

Mr. C. E. Davidson, who was recently appointed manager at Montgomery, Ala., was formerly manager at Brunswick, Ga., and Jacksonville, Fla. He was succeeded at Brunswick by Mr. W. P. Rivers, Jr., formerly of the Savannah, Ga., office.

Mr. E. C. Newton, manager at Little Rock, Ark., has been appointed special agent at that point.

Mr. H. L. Arnold, manager at Hot Springs, Ark., has been promoted to the management of the Little Rock, Ark., office.

Mr. B. H. Arter of St. Louis, Mo., has been appointed manager of the Texarkana, Tex., office of this company. He succeeds Mr. Ensign M. Haldeman, who has been promoted to the managership of the Hot Springs, Ark., office.

Mr. C. W. Chevault, manager of the Johnson City, Tenn., office has been promoted to the management of the Ashland, Ky., office.

Mr. B. F. Lally, of the Dallas, Tex., office, has been advanced to the position of chief operator of the Ft. Worth office.

Mr. D. V. Ferris, chief operator of the Syracuse, N. Y., office spent Thanksgiving with relatives in New York. Mr. Ferris has held his present position for forty-five years.

The Cable.

New Cable to Egypt.—The Eastern Telegraph Company has decided to lay an additional submarine cable between Gibraltar and Egypt, touching at Malta, to cost about $2,000,000.

Bonuses and Profit-Sharing.—The Eastern Telegraph Company and associated companies in celebrating the coronation of King George granted a bonus of one month's pay to every employe of the staff ashore and on board ship who had been in the service for one year prior to May 31, 1911. At the recent annual meeting of the company the chairman referred to the spirit of good feeling existing between the company and its employes, and in granting the additional benefit of the bonus it was the desire that the employes might share in the prosperity of the company. It was suggested that a profit-sharing or co-operative plan might be adopted whereby employes of the company might participate in the profits.

The Telephone.

Mr. Alonzo Burt, vice president and treasurer of the Chicago Telephone Company, has been elected a director of the company succeeding Mr. A. S. Hibbard, now of New York, resigned.

Telephone from Puget Sound Cities to New York.—Mr. Theo. N. Vail, president of the American Telephone & Telegraph Company, while in Tacoma, Wash., recently stated that Puget Sound cities will in another year be able to talk to Chicago and New York.

Reducing Telephone Rates in New York.—The new telephone tolls between Manhattan and Brooklyn boroughs, New York City, went into effect December 1. The rates which were formerly ten cents are now five, and the fifteen cent tolls are now ten cents.

Chinese Prefer Automatic Telephones.—Chinese telephone subscribers prefer automatic tele-

Digitized by Google

phones because of the difficulty they have in calling numbers over the manually-operated switchboards. They are provided with special calling dials having both the ordinary figures and their Chinese equivalents, and a directory printed in Chinese has been provided for them.

Telephone and Telegraph Society of New England.—The regular meeting of the Boston Plant Chapter of the Telephone and Telegraph Society of New England, was held in Boston December 12. Captain Wm. Brophy addressed the meeting on high tension circuits, their characteristics and hazard, and Dr. George B. Magrath described the effect of a current of electricity on the human body.

Radio-Telegraphy.

New Wireless Magazine.—"Wireless News" is the name of a new magazine published monthly in New York by the Wireless News and Advertising Company. It is devoted to wireless telegraphy and wireless as applied to aeronautics.

To Reorganize United Wireless.—A meeting of stockholders of the United Wireless Telegraph Company, New York, is called for the purpose of reorganizing the affairs of the company and taking it out of the receiver's control.

Detecting Thunderstorms by Wireless.—A wireless telegraph equipment is used in a Spanish observatory to detect thunderstorms, local and distant, wireless apparatus being affected by the electro-magnetic waves which accompany a lightning discharge.

Wireless in the Philippines.—Owing to the existence of coral reefs in the waters surrounding the Philippine Islands it has been difficult to maintain telegraph cables. Wireless has replaced these cables in many instances and has practically solved the question of insular communication.

Wireless Interconnection of Colleges.—A movement has been started toward connecting the more important universities and colleges of the country by wireless telegraph. When the distance between colleges is too great for direct communication, messages will be relayed from one or more intermediate college stations.

Wireless Telegraph in Chile.—The Chilean government has accepted the Marconi company's bid to install wireless stations at Arica, Antofagasta, Coquimbo, Puerto Montt, or Valdivia, and Punta Arenas at a cost of $311,786, United States gold, to be completed within fifteen months. These, with the stations at Valparaiso and Talcahuano, will make a circuit from Arica to Punta Arenas, a distance of over 2,000 miles.

Two Wireless Operators for Each Steamer.—Mr. William J. Bryan suggests legislation requiring the assignment of two wireless operators to each steamer at sea. He was a passenger on the steamer Prinz Joachim which went ashore recently in the West Indies and the wireless call for help sent out from the disabled steamer received no response from other steamers for several hours, because, as Mr. Bryan claims, ships carry but one operator and the operators were not on duty at the time.

Wireless in Sweden.—The wireless telegraph station at Nya Varfvet, a suburb of Gothenburg, Sweden, formerly used only for naval and military purposes, has been opened for commercial business by the Swedish Royal Telegraph Department. The system used is Telefunken. The wave length in meters for receiving is 600 and for sending 1,000—1,500. The primary power is about 50 horsepower. The radius of action in the daytime is 750 miles and at night 1,250 miles. The Morse code is used, but there is no special ruling to confine the station to that code. The toll for messages from ships is $0.0268 per word, with a minimum of $0.268 per message. This is, of course, exclusive of the ship's charges. It includes delivery in the city of Gothenburg. Messages to other points in Sweden are subject, in addition, to the usual inland charge of 0.0134 per word. A charge is always made for the address and signature.

Obituary.

George H. Stapley, aged 55, of Chicago, for many years in the brokerage business and a partner of the Odell Commission Company, died in Chicago, Ill., December 2.

Colonel E. A. Hawkins, aged 68 years, a veteran telegrapher, died at Upper Sandusky, Ohio, on December 5. He was a member of the United States Military Telegraph Corps during the Civil War.

Frank W. Ross, aged 19 years, a telegrapher at Colliers, W. Va., died at that place recently. He weighed 425 pounds and measured sixty-four inches around the waist. A casket was specially constructed to contain the remains, which were buried in Port Washington, Ohio.

Willis Derwin Chandler, aged 30 years, son of Colonel Albert B. Chandler, chairman of the Board of Directors, Postal Telegraph-Cable Company, New York, died at Pinehurst, N. C. December 11 after a lingering illness. Interment took place at Randolph, Vt., December 15.

John Henry Stevenson, aged 50 years, for the past twenty years in the service of the American Telephone and Telegraph Company, New York, died at his home in Brooklyn, November 23. Mr. Stevenson was a graduate of Yale and was very popular among his office associates and telephone people generally. He was a brother of Mr. F. A. Stevenson, general superintendent of plant for the same company at New York.

Early Struggles of the Telegraph and Telephone.—The New York *Tribune* of November 29 printed an interesting article headed "Telegraph's Story Full of Romance." It told of Professor Morse's struggles in establishing the telegraph and the skepticism and ridicule with which the telephone was received. The Atlantic cable and wireless telegraphy also receive brief mention.

Digitized by Google

Deferred Cable Service Introduced by the Western Union.

Two new forms of trans-Atlantic cable service were instituted by the Western Union Telegraph Company on December 6. They are known as cable letters and week-end letters, and a deferred press service was also put into effect.

Following is President Vail's announcement of the institution of the new service:

"These cable letters, weekend cable letters and deferred press messages are not offered as a substitute for prsent cable service, but are intended to place the Atlantic cables within reach of the public at rates which will encourage their use for social and business communications which are now subject to the delay of over-sea mails, and which are of sufficient importance to justify a moderate charge for the use of the cable while not of such pressing urgency as to warrant the cost of an expedited cable service.

"Cable letters and weekend letters may be filed in any city or town at any open office of the Western Union, the Anglo-American and the Direct United States Cable companies to be forwarded to the cable terminus at New York, Boston or Montreal by mail or telegraph at the option of the sender, whence they will be cabled at the convenience of the company to reach London or Liverpool in time for delivery on the morning of the second day following their receipt at New York, Boston or Montreal. Weekend letters may be filed as above up to midnight Saturday, whence they will be cabled at the convenience of the company for delivery the following Tuesday morning. Telegraphic transmission of both classes of cable letters between the places of origin and New York, Boston or Montreal, will be charged for, the sender designating the class of service to be used. Postage from the originating point to New York, Boston or Montreal and postage to any European point are included in the tariff.

"Cable letters and weekend letters from the United States destined for the cities of London or Liverpool will be delivered through the mails unless the sender arranges for telegraphic or messenger delivery and those destined for points beyond London or Liverpool will be forwarded by mail, or the company, acting as agents for the senders, will forward such cable letters by telegraph upon the payment of the regular telegraphic toll, until such time as special tariffs are arranged for with the British and other governments.

"Cable letters and weekend letters will be received at any British office of the Western Union, Anglo-American and the Direct United States Cable companies and will be transmitted by mail or telegraph, as provided above, to the cable terminus at London, whence they will be cabled to reach New York, Boston or Montreal on the second day following the receipt at London. Travellers abroad can arrange with any of the above cable companies to forward cable letters received by mail or telegraph to destination in the United States. For telegraph transmission between the points of origin and London, the regular telegraphic tolls will be charged, until such time as special tariffs are arranged with the British and other governments.

"Cable letters and weekend letters from Europe destined to New York, Boston or Montreal will be delivered through the mail unless arranged for telegraphic or messenger delivery. For telegraphic transmission from New York, Boston or Montreal to points of destination in the United States an additional charge at special night letter rates will be made.

"Since the tariff for cable letters and weekend letters is based upon the use of English words without the use of code words, no code words will be accepted for transmission other than registered code addresses. In accordance with the established practice, the address and signature will be counted and charged for.

"The tariff covering transatlantic cable transmissions and postage for mail delivery only will be: For cable letters, $1.50 for 20 words, with 30c. added for each additional five words; for weekend letters, $1.50 for 30 words, with 25c. added for each additional five words. The rate for deferred press messages is 5c. per word."

The first cable letter was sent by Mr. Frank H. Hitchcock, postmaster-general of the United States, from Washington to the British postmaster-general, London, at 12:21 a. m., December 6. It read as follows:

"Availing myself of opportunity to send first cable letter transmitted from this side, I convey to you from American postal service our greetings and best wishes."

There were thirty-five words in the message. In this connection it is interesting to note that the first paid public message sent across the Atlantic by cable was transmitted on July 27, 1866. It was from W. J. S. Donnelly at Heart's Content, N. F., to Wm. Tarbet, Liverpool, Eng., and consisted of twenty words for which $100 was paid. Under the new cable letter arrangement the same number of words can be sent for $1.50. Mr. Donnelly, the author of this message is still living in Havre de Grace, N. F.

Mr. George G. Ward, vice-president and general manager of the Commercial Cable Company, being asked in regard to the cuts in cable rates announced by the Western Union Telegraph Company, said:

"There are four reductions involved, as follows:

"(1) A week-end letter, to be received Saturday and delivered the following Tuesday. This will involve Sunday work. We prefer to give our cable operators a rest on Sunday. We confine our Sunday business to public necessity, like Sunday railroad trains. We shall not adopt it. There is no demand for a service of this kind.

"(2) A newspaper rate of five cents a word. This is a heavy cut of fifty per cent. The purpose is obvious. We think the spectre at Wash-

Digitized by Google

ington is responsible for it. We shall make the same cut.

"(3) A deferred cable letter. This is to be delivered two days after it is handed in. We shall not adopt it, so long as it remains deferred. Ours is not a deferred company. Ninety-nine per cent. of cablegrams call for immediate delivery. Here, too, there is no public demand for such service.

"(4) Plain language cablegrams at half rates. This is not a Western Union move. It was proposed by the Postmaster-General of Great Britain over two years ago. He communicated with the Commercial Cable Company in regard to it at that time. We shall adopt it in accordance with our understanding with the Postmaster-General of Great Britain, entered into long ago. That was before the Bell Telephone Company acquired the Western Union Telegraph Company. The Western Union now seeks to give the impression that it originated this plain word cablegram at half rates. The fact that it is not to go into effect until January 1, while the other reductions go into effect at once, shows who originated it."

A dispatch from London, December 5, says the negotiations which have been proceeding between the Postmaster-General and the cable companies in regard to reduced rates for deferred dispatches have been completed satisfactorily. Press messages to the United States, Canada and Australia, subject to delay, will be accepted at half the present rates, beginning December 15. Ordinary messages in plain language will also be accepted at half price, beginning January 1 on the same conditions. In the United Kingdom the Post Office authorities intend to introduce a cheap night system of telegrams at thirty-six words for sixpence (twelve cents.)

Lord Strathcona, Canadian High Commissioner in London, in a despatch to Ottawa, Ont., says that the Anglo-American and Direct United States Cable companies controlled by the Western Union will also carry the deferred non-urgent press messages at half the present rates. The deferment in favor of urgent messages is estimated at nineteen hours. The British Postmaster-General, he also stated, has obtained the consent of the Pacific Cable Board and of the Australian Government to a similar reduction of their charges for press messages of this class. The tariff of the New Zealand Government is already very low, and a further diminution is not asked. It is also announced that negotiations which have been proceeding for some time with the cable companies for reducing by one-half the rates for plain language non-urgent cablegrams between the United Kingdom, India, the Dominions, the crown colonies, and the United States have proved successful and the new arrangements will take effect on January 1 next. The concurrence of certain foreign administrations will soon be obtained and that scheme will be extended to many other parts of the world.

Telephone Pioneers of America.

A. A. OWENS, VANCOUVER, B. C.

Mr. Archibald Alexander Owens, general inside wireman and installer, Bell Telephone Company, Vancouver, B. C., began his telephone service in Montreal in February, 1889, and is enrolled as one of the Telephone Pioneers of America. He started as a ground man and has worked his way

ARCHIBALD ALEXANDER OWENS,
Vancouver, B. C.

through the positions of lineman, troubleman, inspector, wireman and building wireman and inspector. He afterwards entered the head office of the electrical-mechanical department and was engaged in special service, later becoming switchboard inspector, private branch exchange installer, night man in charge of the switchboard and finally general inside wireman and installer, which position he now occupies.

Charging for Date, etc., on Telegrams. — The Western Union Telegraph Company has petitioned the Public Service Commission, second district, New York, for a rehearing upon the order recently made by the Commission, directing that company to discontinue its practice of charging the Postal Telegraph-Cable Company for certain words inserted on telegrams received from the Postal for further transmission over the lines of the Western Union Company. The Western Union company will ask for a modification of the order made, so that it will be allowed to charge for the name of the place and the State where the message originated, and the word "via," so that three words will be charged for instead of the number of words charged for at present, which is, according to circumstances, four or five.

Threatened Strike. — According to newspaper reports the postal employes of Great Britain contemplate striking about the holiday season.

The First Telephone Exchange.

It was in the year 1877 that Professor Bell was experimenting in Charles Williams' shop at 109 Court Street, Boston. This shop had for nineteen years previous to that date, been manufacturing all the electrical appliances for the Holmes Burglar Alarm Company; in fact, it might have been called a Holmes shop because more than half the work of the shop was for the Holmes Company.

The subject of this sketch, Mr. Edwin T. Holmes, who was carrying on the burglar alarm business in the City of Boston, was of course a frequent visitor to this shop, and one afternoon he found Mr. Williams shouting into a box with a mouthpiece on one end.

"What have you got in that box, Williams?" said Mr. Holmes. Laughingly he replied, "This

E. T. HOLMES.
President Holmes Electric Protective Company, New York.

is what someone calls a telephone and I have got one on each end of my private wire to my home in Somerville, and I am trying to call Mrs. Williams."

This was Mr. Holmes' first introduction to a telephone. From that time he watched developments and in April, 1877, told Mr. Gardiner G. Hubbard that if he ever got two or three of those things so they would work that he would like to show them to Boston. Mr. Hubbard inquired how he would show them, whereupon Mr. Holmes thoroughly explained his burglar alarm protective system to him, stating that he had individual wires running from the various banks and many business houses to his central office for the purpose of protection against burglary; that by pressing a knob he could ring a bell in a bank and the bank could, in return, send a signal into his central office. Mr. Holmes explained how he could construct a switchboard that would throw the circuit from his burglar alarm apparatus on to a telephone when receiving a signal from a bank, or the bank could, by moving a switch, throw in the telephone at their end upon receiving a stated signal from the central office. He said, "I can do even more; I can, upon receiving a signal from one bank, press a knob and signal a second bank and put the two in communication with each other."

This so pleased Mr. Hubbard that he slapped Mr. Holmes across the back and said, "I'll do it—get the necessary appliances ready," and this was the reason that the small switchboard exhibited at the late organization meeting of the Telephone Pioneers of America was constructed, and it was through this switchboard that Mr. Holmes exhibited the telephone to the citizens of Boston for a couple of weeks, using telephone Nos. 6 and 7 in that exhibit.

He was next anxious to do business; there was no company formed, but Mr. Hubbard told him that if he would furnish the money to build the exchange he would rent him the telephones at $10 per year each, whereupon Mr. Holmes immediately began to solicit subscribers for the first telephone exchange, under the name of the Telephone Despatch Company, which was established in a loft he hired above the one he was occupying for his own business, at 342 Washington Street, Boston.

Some time later the first telephone exchange in New York was started in the Holmes Burglar Alarm Company's office at 518 Broadway, a building that is still occupied by the Holmes Company, and Mr. Edwin Holmes, the father of the subject of this sketch, was the first president of the New York Company.

Mr. Holmes also has the distinction of having hired the first girl who ever operated a telephone, and the wisdom of this step has been fully borne out by experience, since there are thousands of young ladies now in the service. Mr. Nat Lilly of the New England Company, in Boston, was one of Mr. Holmes' first operators and Mr. J. J. Carty, now chief engineer of the American Telephone and Telegraph Company, New York, also entered the telephone service in this first exchange at 342 Washington Street, Boston. Mr. Holmes later sold his telephone business to the New England Telephone Company when it was formed.

Mr. Holmes is now president of the Holmes Electric Protective Company in New York City.

Wireless in the Antarctic.—The Antarctic exploration steamer "Deutschland," which recently sailed from Buenos Ayres, Argentine Republic, is equipped with a wireless outfit having a range of about 600 miles. It is thought that the steamer will never be out of the range of the wireless station at Tierra del Fuego for the receipt of signals.

Every telegrapher should study the Lessons on Technical Telegraphy now running in TELEGRAPH AND TELEPHONE AGE. Subscription price, $2.00 per year.

Western Union Cable Steamer "Robert C. Clowry."

The Western Union Telegraph Company has about 150 submarine telegraph cables under the rivers, bays and creeks of New York harbor at sixty different crossings. The length of these cables varies from 500 feet to thirteen miles, the latter being the cable between the Battery and Coney Island.

With so many links exposed to the ravages of ship anchors, and other damaging influences, such as chafing on rocks, etc., it can readily be understood how a cable steamer may be kept busy making repairs.

The cable steamer "Western Union" which has been laying and repairing cables for the Western Union Company for the past 35 or 40 years has in late years been taxed beyond her capacity owing to the growing weights in cables and a widening radius of service. The new cable steamer "Robert C. Clowry," illustrated herewith, was built along modern lines and intended for the heavier work now demanded of a boat of this class. She is used for the laying, recovering and repairing of telegraph deep-sea and harbor cables. The boat is 150 feet long and 32 feet wide, and when fully loaded draws 11 feet 6 inches of water. She has two keels and two rudders and is propelled by two screws, each driven by a 500-hp. compound engine.

FIG. 1.—WESTERN UNION CABLE STEAMER "ROBERT C. CLOWRY."

The cable reel is located on the main deck forward of the pilot house, and below deck is a cable tank eighteen feet in diameter and twelve feet high, having a capacity of about seventy miles of one-inch deep-sea cable.

Two horizontal drums, five feet six inches in diameter, are mounted on the port and starboard sides of the cable tank, with the driving engine and connecting gear placed between. This machinery is capable of lifting a deep-sea type of cable from a depth of one mile.

At the bow of the ship a strong iron frame is fixed so as to extend beyond the bow and on this frame are mounted two large sheaves to accommodate the cable leading to the port or starboard drum. Near the bow is a capstan driven by worm gear, slow speed, capable of lifting twenty tons. This can be used for lifting anchors or driving another gear when necessary. Forward of the deep-sea machinery is a large vertical reel which is run by an independent engine. Ten miles of deep-sea type of cable can be coiled on this reel and a proportionately smaller amount of the heavier types, such as the harbor multiple type of cables.

Attached to the lattice iron mast is a large boom of the same construction. This boom can be swung around to any required angle, so that it can be used for hoisting weights up to twenty-five tons or underrunning cables. Heavy types of

Digitized by Google

cable when coiled on the reel are paid out by means of this boom.

The ship was designed for river and harbor and along shore work in moderate depths. Since being put in commission she has made several repairs in quick time between New York and Nova Scotia in depths varying from about 100 fathoms in the vicinity of Sable Island to 750 fathoms southeast of Montauk Point, Long Island. The repairs at the latter place were made at the greatest depth in which this steamer has so far operated. Apart from the deep-sea work she has done considerable telephone and telegraph heavy cable work in various localities.

The deep-sea part of the work is by far the most interesting, everything connected with such operations requiring close calculation. The locating of trouble requires experts in electrical testing in ocean work. Skill in navigation where it is necessary to put the ship right on the line of the cable in any part of the ocean and close to the position where the fault was located is of course very essential. The jointing of the gutta-percha core in making a repair can only be done by those accustomed to the work.

The electrical testing room is an interesting feature of the boat. A modern deflecting, Sullivan type, galvanometer is used, with Wheatstone bridge, condensers and keys for bridge capacity tests, and instruments for Morse and mirror working. On several occasions communication has been held from the ship when off Nova Scotia, with Penzance, England, a distance of over 2500 nautical miles.

The "Robert C. Clowry" is manned by a crew of thirty-six persons, the officers being: Capt. Theo. Royen, master; H. Schmidt, chief officer; H. Baker, chief engineer; R. Gundry, first assistant engineer; David Lynch, division cable electrician and Alexander Kline, general cable foreman. Capt. Royen also has supervision and direction over the "Western Union," which is commanded by Capt. G. G. Olmstead, while that steamer is making repairs in New York harbor and immediate vicinity.

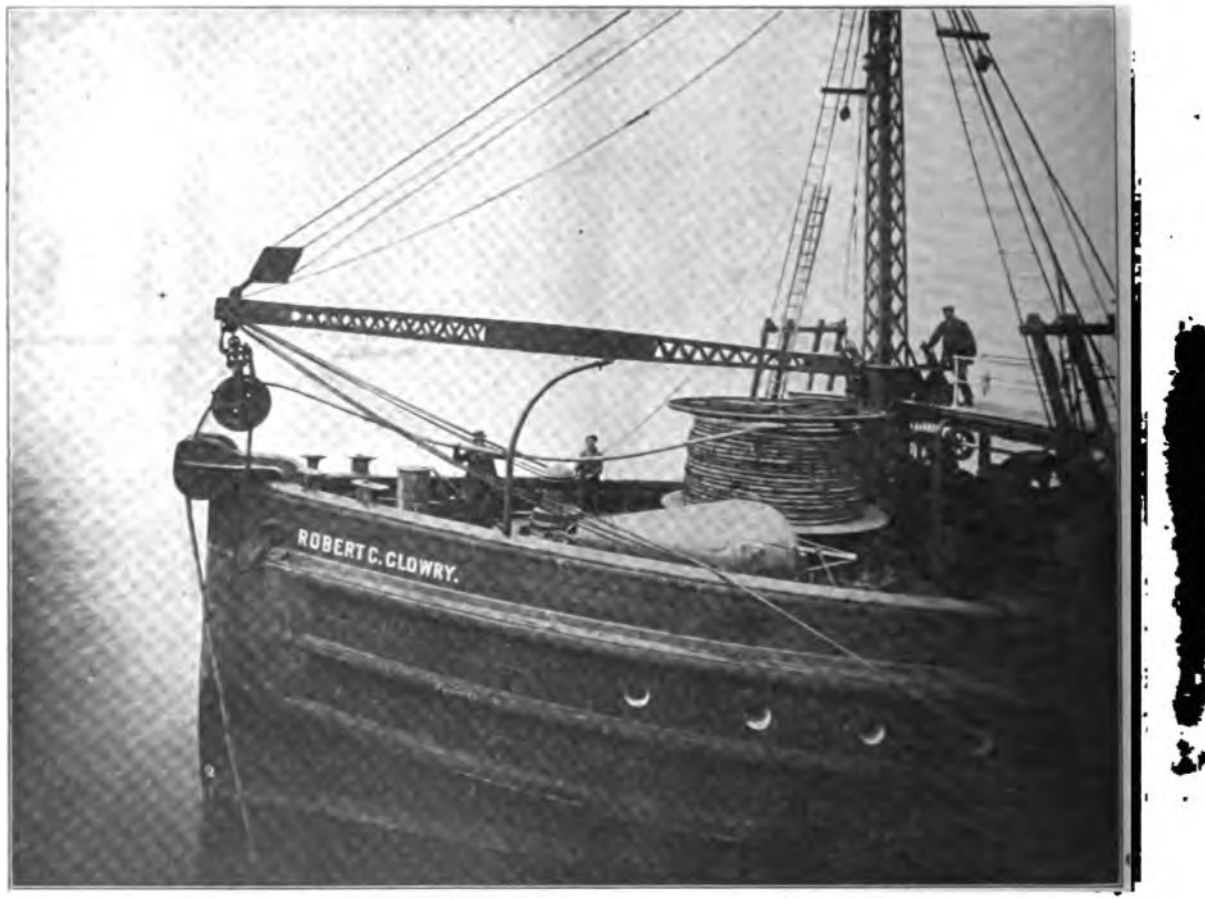

FIG. 2.—BOW OF CABLE STEAMER SHOWING THE CABLE REEL.

Joy Riders and Poles.—Joy riders are often charged with recklessness in colliding with telegraph and telephone poles, but when it is remembered that there are 32,000,000 poles in the country, it is surprising that they hit so few. It is not an easy task to dodge 32,000,000 poles.

Paris to Morocco by Wireless.—Wireless communication was held recently between the Eiffel tower in Paris and Fez, Morocco.

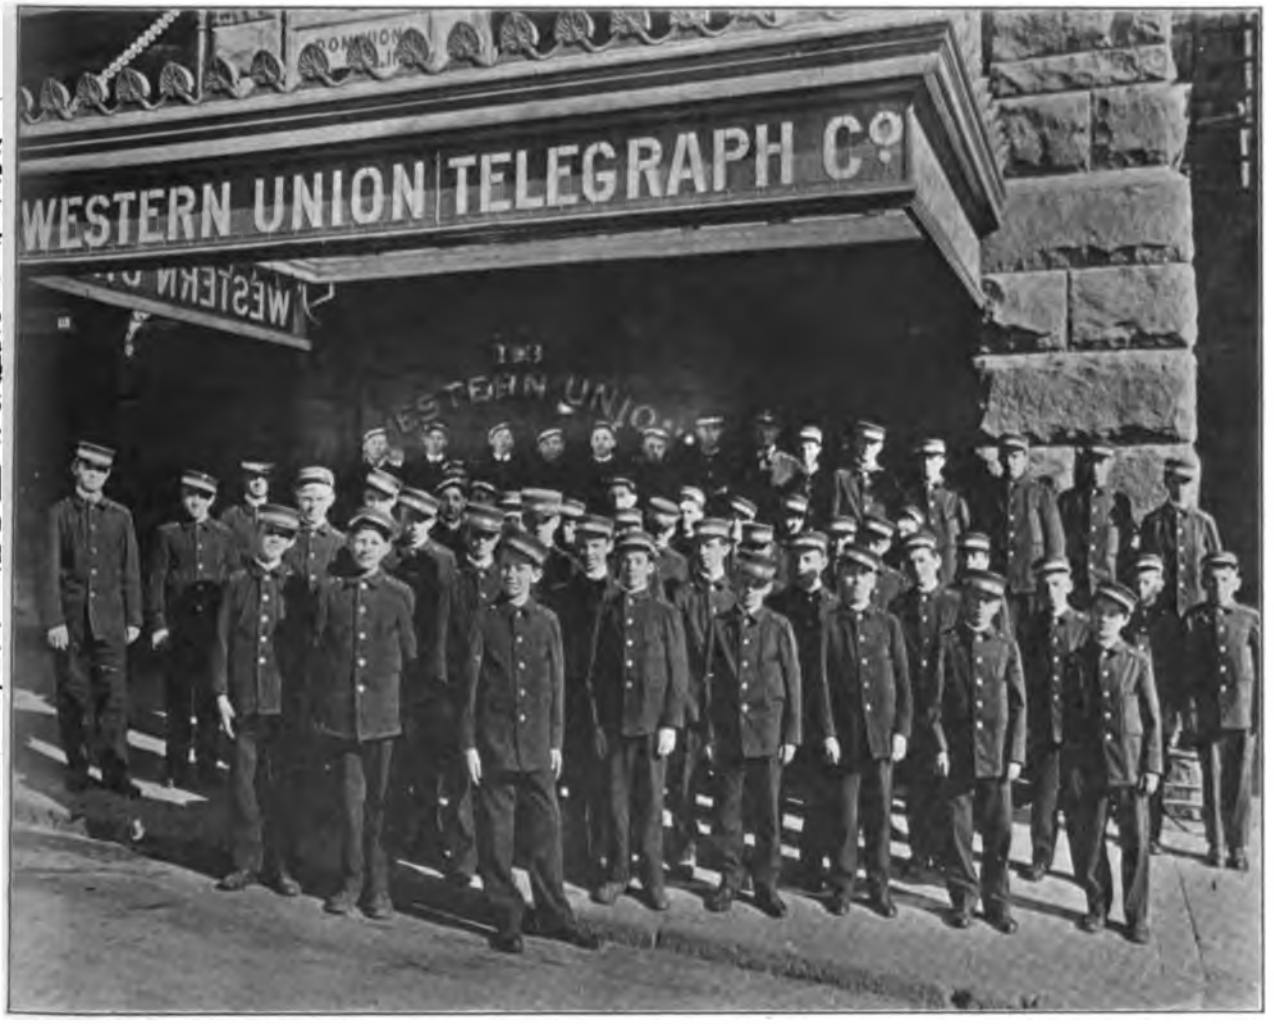
Seattle Western Union Messengers.

The accompanying illustration shows the messenger force of the Western Union Telegraph Company at Seattle, Wash., and the unusual bright and intelligent appearance of the young men will be at once noticed.

In sending us the photograph from which the cut was made Mr. E. Boening, district commercial superintendent at Seattle refers in complimentary terms to his messenger force. He states that it is unsurpassed in intelligence, discipline and ability to handle every character of service entrusted to it.



MESSENGER FORCE OF WESTERN UNION TELEGRAPH COMPANY AT SEATTLE, WASH.

The organization and recruiting of the force is the result of patient effort and hard work, and by providing sanitary quarters and treating the boys fairly the company has secured the good will of the general public in its efforts to build up a first-class messenger service.

"There are approximately fifty-five messengers on our force," writes Mr. Boening, "and by securing the right kind of boys, we have, in less than a year, been able to promote sixteen of them to positions in the operating, bookkeeping, delivery and other departments, where each one of them is making good, thus demonstrating that the careful selection of material for messenger forces is of the greatest advantage, not only to the boys themselves, but to the company. The discipline maintained is perfect, and the day and night forces are supervised by a 'sergeant' who keeps the boys up to the mark, and especially sees that the raw recruits are fully instructed as to their general behavior and the proper performance of their work.

"The boys are provided with clean quarters, in which there are adequate wardrobe facilities, together with lunch tables and instruments to permit of their practicing telegraphy when opportunity offers."

Mr. T. F. Keech, subscriber's representative of the Michigan Telephone Company, Ann Arbor, Mich., writes: "I like the advice given to young men as published in TELEGRAPH AND TELEPHONE AGE. It is what is needed. If followed it will bring success to every man."

Hints to Managers.*

BY I. N. MILLER, DISTRICT COMMERCIAL SUPERINTENDENT, WESTERN UNION TELEGRAPH COMPANY, CINCINNATI, OHIO.

The dictionary definition of the word manager is "One who manages; a person who conducts business with economy and frugality." A manager of a telegraph office is one who is not only economical in the expenditure of money and applies what is spent to a profitable purpose, but one who can solicit and secure patronage or, in other words, sell what his employer has to sell. Telegraph companies have service to sell; the service consisting principally in transmitting quickly correspondence and communications, which, owing to their nature can not be transmitted by mail in time to answer their purpose.

The most successful manager is one who can sell the most service and get the most for it. It is true that rates are uniform, but what the corporation gets is the difference between receipts and expenses, and this varies in proportion to the efficiency of the management.

The best manager is, therefore, one who produces the best results, not for a week or month, but for years. To underpay or overwork employes will not produce the best results, as they will resign and frequent changes demoralize the force. The successful manager in this direction is one who pays what labor is worth in the market and demands honest service in return. The treatment, surroundings and conveniences must be such as to attract and satisfy the employes; then they have no incentive to resign and go elsewhere and the best results are secured.

In the present day in this country competition in almost all industries is active and it requires very careful management to secure satisfactory results. Managers of the various industries who patronize the telegraph the most freely are often hard working persons with a multitude of detail and they are easily affected either in our favor or against us. A single kind act will often cause them to be your friend and they will favor you with their business or the least slight or injudicious remark will cause the reverse.

A manager should be personally acquainted with his customers because he can then tell best how to favorably impress them. The old adage: "Where one will not, two cannot fight" is applicable to the telegraph business. The successful manager must have complete control of his temper, as it often happens that the persons controlling the largest patronage are at times the most unreasonable, and nothing but the most skilful tact will prevent the loss of business.

The successful manager must be tactful in selecting, retaining and working his force. He must cultivate a personality that is pleasing and attractive to the public in order to attract patronage and if he accomplishes this, he must watch every detail of the service and know personally that all employes are performing their duties properly. Every complaint from customers must be courteously and promptly looked after, and above all stick to the truth and do not try to deceive them. If they once find you tricky or dishonest, they will never again have any confidence in you.

In order to attract business, there are many things that should not be overlooked. If a business man enters a telegraph office and finds everything in disorder, the employes boisterous and apparently unemployed, the room dirty, it gives at a glance the impression that the manager or person in charge is not worthy of the title he bears and the visitor has little confidence in the service he can secure.

The manager of a telegraph office receives the highest salary at that office and should be the most active worker. If he doesn't work, no one else will render the service a successful business must have. The managers of telegraph offices as a class are above the average of intelligence. They come into contact with the best business element and have great advantages, which in other lines of business, they would not have. If there is any development in a young man, it will have every opportunity to grow and expand in the position of manager. But to grow means to work, and he who does not like work, and is always looking for an easy position, will soon be distanced and there is no future for him. If a manager has the talent to attract business and successfully handle men, but cannot control himself and spends the company's money, he has committed an unpardonable offense and all other good qualities come to naught. The money is what corporations are in the business for, and any one who undertakes to take this away from them wrongfully will never again be able to gain their perfect confidence.

*Journal of the Telegraph.

Cincinnati's First Telegraph Office.

The following interesting facts are gleaned from the Christmas number of the "Seventh District Blue Book," published by the Western Union staff at Cincinnati, Ohio.

The first telegraph office in Cincinnati, Ohio was opened for business August 20, 1847. Mr. C. T. Smith was the operator in charge. The next day, under the caption "The First Flash," the Cincinnati *Gazette* said, among other things:

"Cincinnati and Pittsburg shook hands yesterday afternoon and exchanged compliments by means of Mr. O'Reilly's telegraph."

On September 24, 1847, the Cincinnati *Gazette* announced the completion of the O'Reilly line to Louisville, Ky., the House printing telegraph being used.

One of the first circulars issued read as follows:

"To all Offices—I understand it is becoming common for some operators to receive by sound; never do this; do not trust your ear; always let your paper run.

(Signed) J. D. REID, Supt."

CHANGES OF ADDRESS.—In ordering a change of address the old as well as the new address must be given.
REMITTANCES to Telegraph and Telephone Age should be made invariably by draft on New York, postal or express money-order, and never by cash loosely enclosed in an envelope. By the latter method money is liable to be lost, and if so remitted is at the risk of the sender.

December 16, 1911.

Knowledge vs. Money.

There are some persons connected with the telegraph and telephone services who think that what they and other employes need is more money rather than more education. Verbal statements and letters to this effect have been made to and received by us, and it seems hardly possible that any one in these enlightened days can soberly entertain such views in the abstract. However, it is one thing to make a statement and another thing to believe it, and few men are consistent in this respect.

We do not agree with our complainants that money should take precedence over knowledge in our material affairs. We do not doubt that there are many cases where more money would do good, but we also know that in many instances where persons think they ought to have more money it would do them more harm than good if they had it. The great trouble is that most of us allow ourselves to be completely dominated by the desire for financial gain. Money is a good thing when properly utilized, and the desire for and acquisition of it for other than selfish purposes is highly commendable, but the fact is indisputable that most people yearn for money in order to satisfy their craving for things that do them no good.

In all ages knowledge and education have been held to be the most desirable possessions of man. A man with knowledge and experience has the foundation for the acquirement of money. Money, of course, is necessary for our well-being, as well as knowledge, and both should be used wisely.

If men would bear in mind that knowledge can buy money and that money cannot buy knowledge they would get a more accurate perspective of the facts of existence.

He who neglects to improve his opportunities because he thinks he is entitled to more money for his present services, is an obstructionist, not only to himself, but to his employer. As a rule, he would get more money if he were worth it, and the rule very generally holds good.

If men would adopt the principle of living within their incomes and increase their earning power by increasing their knowledge there would not be so much dissatisfaction with present conditions.

The Welfare of Messenger Boys.

It sometimes seems as if the telegraph companies were trying to eliminate the messenger boy from the service by the introduction of modern ideas and improvements, but the boy still survives and it is not likely that his duties will be dispensed with very soon.

In the development of the telegraph business the messenger receives as much consideration as any other branch of the service, and the lot of the present-day boy is infinitely superior to that of his predecessor of a few years ago. In the larger offices the boys are afforded opportunities to learn the higher branches of the business, such as operating, bookkeeping, etc., and the tendency is to make clean men of them, mentally and physically, baths, besides other helpful agencies, being provided for their physical needs.

We have several times in the recent past published pictures of messenger forces in different cities and in this issue we present one of a messenger force at Seattle, Wash. In studying the faces of the boys in this picture it will be noticed at once that they manifest intelligence to a greater degree than is usually found in an average group of the same number of boys anywhere. By exercising care and wisdom with reference to the selection of their messenger boys the companies are storing up sound material for the future upbuilding of their main structure.

Proposed Monument to the Late James D. Reid.

The proposition to erect a monument over the grave of the late James D. Reid, at Rochester, N. Y., which was suggested by president Charles P. Bruch at the Magnetic Club dinner on November 15 is meeting with hearty acquiescence and support.

For many excellent reasons the last resting place of one who was so beloved by his associates as was Mr. Reid should be marked in more fitting manner than by a small headstone. The great telegraph fraternity owe it to his memory to express their appreciation of the interest he took in their behalf and recognition of his sterling character. He was the first telegraph superintendent; the first president of the Telegraphers' Mutual Benefit Association and one of its most active promoters, and one of the organizers of the Old Time Telegraphers' and Historical Association and a former president, besides being the author of a volume of telegraph history and other works

Digitized by Google

of like character. The memory of a man who has devoted so much of his life in the interest of his fellow men certainly deserves to be perpetuated for the benefit and admiration of posterity.

Two telegraph organizations have already taken co-operative action in the matter, in addition to the Magnetic Club, viz.: the Society of the United States Military Telegraph Corps and the New York Telegraphers' Aid Society, and others will unquestionably do likewise in due time.

It would require much space to enumerate the various official positions held by Mr. Reid during his telegraph service between 1845 and 1890, when he became United States Consul at Dunfermline, Scotland.

Telephone Superseding the Telegraph.

The use of the telephone for train dispatching purposes in this country has been growing for several years and its practical superiority over the telegraph has been demonstrated beyond question. Many of the railway telegraph superintendents are now introducing the telephone on their lines for message service and we see in this fact the opening up of great possibilities. If the telephone can be used successfully by railroads in transmitting their service messages what is to prevent its more general use for public business?

A silent revolution is going on in the transmission of intelligence but how it will end it would be rash for anyone to predict. At the present time the telephone seems to be the more active and shows a tendency to drive its older relative —the telegraph—into outer darkness. The great strength of the telephone lies, of course, in its wide range of applicability and its flexibility.

The railroad telegraph superintendents may or may not realize it, but they are performing a great work in the universalizing of the telephone as a means of communicating intelligence to distant points.

Some Observations from Mr. Edison.

Mr. Thomas A. Edison denies that he intends to experiment with his storage battery for aeroplanes. He says he has not experimented with aeroplanes for thirty years.

"I keep close to earth," he said. "If I experimented I'd break my neck the first week."

Among other characteristic remarks Mr. Edison said:

"I still get lots of suggestions from cranks. They want my idea on everything from a washing-machine to a rat trap. Most of them talk perpetual motion.

"Yes, I'm still working on the old schedule. About four hours' sleep. I had a hundred men working for me once on that schedule, and they were a healthy bunch. I don't take any exercise except what I get walking around in the laboratory. Eat everything but only a little. I only eat when it is necessary, about one-fourth as much as the average man. Just enough to keep up my 170 pounds. I've got a scale in my bathroom. I hop on that every few days. If it's below 170 I eat little more just to raise the ante. I bolt everything, but I eat so little that it doesn't hurt me. I like mince pie, fine. Everything is brain food. I don't eat the breakfast foods. We have a boiler inside of us, and we just fill it up with fuel. We are nothing but machinery, meat machinery.

"Is there a chance for the young man? Yes, better than ever. A man came to me the other day and asked for two $10,000 men. I couldn't furnish them. There are plenty of threes in the world. Few tens. The college man is not the practical man. Colleges are better than they once were, but they aren't practical yet. They are all right for lawyers, but this country needs engineers, not lawyers. Colleges are for the social side and for the literary. Not worth while, generally."

Electrical Testing Made Easy.

In describing the methods of transmitting dispatches, etc., in the new headquarters of the Union Pacific Railway, Omaha, Neb., a daily newspaper reporter got beyond his depth when he undertook to enlighten his readers on the technical features of the plant.

"Another device that has been installed in the telegraph department," he says, "is the trouble locator. When a wire fails to work as it should, the trouble indicator is attached to the particular line and it commences to get busy. It is an apparatus having a dial something like a small clock, but instead of its face being divided into spaces indicating hours, it shows only ohms, and there are any number of them.

"The ohm is a telegraph measurement and there are eight of them to the mile. The pointer on the dial moves around like the second hand on a watch, and if there is trouble out between here and Cheyenne it stops at the figure indicating the number of ohms distant from Omaha where this particular trouble is located. Then the superintendent of the service simply divides the number of ohms by eight and he has the trouble spot pretty closely located. Then all there is to do is to get in communication with the linemen at the nearest point and get them started on the repair work."

Mr. G. W. E. Atkins, vice-president of the Western Union Telegraph Company, New York, in remitting to renew his subscription, writes: "I shall gladly aid in the expansion of your circulation as I regard your paper as eminently practical and useful."

There is something of value to everyone in each issue of TELEGRAPH AND TELEPHONE AGE, and this value should not be measured by the cost of a subscription but by the influence the paper has on the individual.

Course of Instruction in the Elements of Technical Telegraphy—V.

(*Copyrighted.*)

(Continued from page 796, December 1.)

[We began in our issue for October 16 the publication of a course of instruction in technical telegraphy. The course is published for the benefit of those of our readers who desire to fit themselves for better positions in their vocation. It is elementary throughout and will be divided into chapters, following one another in logical order.

The course has received the hearty commendation of telegraph officials and experts for its scope and accuracy and its sound practicability. In each chapter examples will be given in order to illustrate the application of the rules to practical cases, and each chapter will be followed by a series of questions pertaining to the subject of the chapter, to be worked out by the student in order to review his progress.

The mathematical section which is now running will carry the student through fractions, decimals, proportion, elementary algebra, etc.]

ALGEBRA.

Algebra is that branch of mathematics in which the quantities are represented by letters, and the operations to be performed upon them are indicated by signs.

The sign + is called the plus sign and indicates the addition of two or more quantities. Thus, a + b denotes that the number represented by a is to be added to the number represented by b.

If a quantity be added to itself several times, we generally write it but once, and then place a number before it to show how many times it is taken. Thus, a + a + a + a + a = 5a. The number 5 is called the co-efficient of a, and denotes that a is taken 5 times.

When the co-efficient is 1, it is generally omitted. Thus, a and 1a are the same.

The sign — is called minus, and denotes that one quantity is to be subtracted from another. Thus a — b is read, a minus b, or a diminished by b.

The multiplication of quantities which are represented by letters is indicated by writing the letters one after another without interposing any sign. ab signifies the same thing as a × b.

There are two signs to denote division a ÷ b and $\frac{a}{b}$

Every quantity written in algebraic language, that is with the aid of letters and signs, is called an algebraic quantity or the algebraic expression of a quantity.

Thus, 3a is the algebraic expression of three times the number a.

3a — 5b is the algebraic expression of the difference between three times a and five times b.

When an algebraic quantity is not connected with any other by the sign of addition or subtraction, it is called a *monomial*, or a quantity composed of a single term. Thus, 3a, 7ab are monomials, or single terms.

An algebraic expression composed of two or more parts, connected by the sign + or —, is called a *polynomial*, or quantity composed of two or more terms.

Thus, 3a — 5b is a polynomial.

If two or more terms of a polynomial contain the same letters, they are called *similar terms*.

Thus, in 7ab + 3ab — b, the terms 7ab and 3ab are similar.

When a polynomial contains similar terms it may be reduced to a simpler form. Thus, the expression 3ab + 2ab is evidently equal to 5ab.

In adding similar terms we take the sum of the co-efficients and annex the literal part, that is, the part denoted by letters.

Example: Reduce the polynomial abc + 4abc + 5abc to its simplest form.

Solution:

abc
4abc
5abc
———
10abc
———

NOTE. The first term abc has a co-efficient 1 which is understood.

Of the different terms which compose a polynomial some are preceded by the sign +, and the others by the sign —. The former are called additive terms; the latter, subtractive terms. When the first term of a polynomial is not preceded by any sign, it is understood to be affected with the sign +.

Example: Reduce to its simplest form the expression

3ab + 5ab — 3ab + 4ab — 6ab — ab.

Solution:

Additive Terms	Subtractive Terms
+ 3ab	— 3ab
+ 5ab	— 6ab
+ 4ab	— ab
Sum + 12ab	Sum — 10ab

But 12ab — 10ab = 2ab.

Hence for the reduction of the similar terms of a polynomial we have the following:

RULE (1). *Add together the co-efficients of all the additive terms, and annex to their sum the literal part; and form a single subtractive term in a similar manner. Then subtract the lesser co-efficient from the greater, and to the remainder prefix the sign of the greater co-efficient to which annex the literal part.*

Example: Reduce the polynomial 4abc — 8abc — 9 abc + 11abc to its simplest form.

Additive.	Subtractive.
4abc	— 8abc
11abc	— 9abc
15abc	— 17abc

15abc — 17abc = — 2abc

NOTE. The smaller co-efficient being 15, it is subtracted from the — 17, and the — sign prefixed to the remainder.

(*To be Continued*)

Deep-Sea Cable Repairing.

BY DAVID LYNCH, DIVISION CABLE ELECTRICIAN, WESTERN UNION TELEGRAPH COMPANY, NEW YORK.

When a submarine cable is broken the fault is located from the shore stations at both ends and the results compared. It sometimes happens that the broken ends present different conditions for testing, so that the tests from each end will be of a different character. It has frequently happened that injury caused by ship's anchors will leave the conductor well exposed at one end and insulated or partially insulated at the other end. In the latter case the pressure of the water closes the gutta percha over the end of the conductor. The condition of the end indicates to the electrician the nature of the test best calculated to give accurate results.

The tests most generally employed are insulation, conductor resistance and capacity. The conductor resistance test is the one most frequently used in locating faults, and the methods employed vary with the conditions. If a second cable is available between the two stations a loop test can be taken, but if not, straight single line tests are taken from both ends. If the cable is completely parted a "break test" is used. The Kennelly system is very good, the theory being that if the testing current is increased four times, the resistance at the break is reduced one-half. If the cable is only partially grounded and weak signals reach the distant end the Blavier test can be used, and if the cable shows only a slight escape an overlap test will give good results.

The great difficulties encountered in deep-sea cable testing as compared with land cables are due to strong earth currents, polarization at the fault and high static capacity. Frequently the earth current varies very rapidly and consequently the balancing is done to false zero, that is, to the deflection of the galvanometer from the derived earth current when no local battery is on the cable. The polarization at the fault varies according to the condition at the end. It will be strongly noticeable if the cable is parted and the end gets buried in mud, thereby making a small copper surface contact with an irregular muddy substance; or, if the insulation gets bruised through mechanical injury from rocks and ships' anchors when a good contact is not made between the copper conductor and the iron armor of the cable. The fault will polarize with either pole of the battery depending on the nature of the injury. As a rule the zinc pole of the battery will clean a fault and the copper pole will partly seal it up, but where the injury is such that only a small hole admits the salt water to the conductor, hydrogen bubbles will be formed on the surface when the zinc pole is used, which will tend to partly insulate the cable at the fault. In such cases tests are made with the copper pole to line. Much depends on the experience of the electrician in judging the methods to be used under widely varying conditions.

It is difficult for the amateur to tell whether the throw from the cable is due to static capacity, polarization or earth currents.

If the end should be insulated a static capacity test is taken. For lengths up to about 50 miles fairly good results can be obtained with the ordinary comparative throw method, using a standard condenser to compare with the cable, but with longer lengths a balancing system is used, similar to the Wheatstone bridge method. A high capacity condenser is put in series with the cable and resistances are arranged the same as are the arms of a Wheatstone bridge, which can be adjusted to bring the charge of the condenser and cable to the same potential. The various tests have been fully described in text books on submarine cable working.

After the fault is located the position is noted on the chart which shows the route of the cable as laid. This gives the navigator of the repair ship the latitude and longitude where it is necessary to place the ship. On arriving at the position, nautical observations are taken to confirm the position, and the ship is then placed as near as possible to where the fault was located. Soundings are then taken to get the depth of water. A mark buoy is next placed on the line of the cable with the necessary amount of buoy rope and chain to reach the bottom. Attached to the chain is a mushroom anchor which keeps the buoy in position. On top of the buoy is placed a staff about eight feet long which carries a flag or bunting at the top and two large lamps near the base. These lamps will burn about four days or longer according to whether oil or gas is used. This buoy then serves as a marker to operate from.

After placing the buoy, the ship is moved to a point about two miles from the cable line and a grapnel is lowered which is slowly dragged along the bottom across the line of the cable. This grapnel is made with a strong iron stock having protruding curved prongs which engage any obstruction met while being dragged over the bottom. The rope attached to the grapnel passes over the horizontal drum of the cable machinery where several turns are taken around the drum, the number of turns depending on the depth of water. This rope also passes under the sheave of the dynamometer which registers the strain that the grapnel encounters.

If the grapnel should strike against a rock a sudden jar is usually felt on the dynamometer and the grapnel slides off, but when the cable is hooked, a steadily increasing strain is noticed on the dynamometer indicator. When this latter indication is noted the ship is stopped and put astern to ease up the strain on the cable. The cable engine is then thrown into gear with the horizontal drum and the grapnel rope is slowly hove in. When the grapnel reaches the bow sheaves with the cable, the heaving-in engine is stopped and strong Manila ropes are attached to the cable on each side of the grapnel and securely stoppered. The cable is then cut at the bight between the

Digitized by Google

ropes and one end is paid out and the other picked up at the same time. The end on board is immediately connected with the testing room, where the electrician calls up the shore. A man is continually kept on watch at the shore stations from the time the ship is expected on the ground until the repair is completed. If the shore answers the call, the electrician takes a quick test for insulation and conductor resistance, usually taking only a few minutes to do this. If he finds the cable normal he notifies the shore that the end will be buoyed temporarily.

The other end is then connected to the testing room and the distance to the fault measured. After getting his figures the cable is hove in until the fault comes on board. If it is a complete rupture the other end has to be grappled for in the same way as before.

When communication is established with the second shore station, and the cable testing satisfactorily, the end is spliced on to the cable in the ship's tank. After the splice is completed the ship pays out sufficient cable to reach the end which was left buoyed. While paying out communication and testing is kept up, so as to watch for any weaknesses that might develop during the work.

On reaching the buoyed end the buoy is taken on board and the rope leading from the buoy to the cable is hove in by means of the cable machinery. When the cable end is reached, it is again connected with the testing room and re-tested. The distance to shore can be told from the conductor resistance obtained, and is usually in accord with the position determined by the nautical observations.

The cable now testing "O. K.," both ways, the two stations are notified that the final splice will be made and communication restored in about one hour. When the splice is completed ropes are attached on each side of the splice and the cable is slipped overboard gently by slacking up on the ropes. When sufficient rope has been paid out to assure that the buoyancy of the water relieves the strain on the splice, the ropes are cut and the cable sinks to the bottom. The ship then proceeds to pick up the mark buoy and the operation is complete.

It frequently happens that several buoys have to be placed where more than one break has occurred in the same locality or the cable may part during the picking-up operations, owing to weak armor, as in the case of old cables.

Mr. A. J. Hartman, manager of the North American Telegraph Company, Red Wing, Minn., in renewing his subscription for another year send us the following:

"I never have seen the Ocean
"I never have seen the Sea
"The Banks of the Mississippi
"Are grand enough for me."

and adds "Keeps the AGE a-rolling in to me."

Dispensing With the Repeating Sounder.

BY E. C. DAVIS, PLANT DEPARTMENT, WESTERN UNION TELEGRAPH COMPANY, SAN FRANCISCO, CAL.

Referring to Mr. J. P. Ferriter's article in TELEGRAPH AND TELEPHONE AGE for November 16, relative to dispensing with the repeating sounder between the neutral relay and the operating local, I desire to say that I tried this arrangement between Los Angeles, Cal., and Flagstaff, Ariz. I had Flagstaff reverse his long end and tap, taking the local off the rear point of the neutral relay, direct at first, but later I inserted the repeating sounder after reversing the points on it. My idea in doing this was not to dispense with the repeating sounder so much as to have the short end of my battery oppose the incoming signals, Flagstaff having it repeatered into a single wire. For this reason it is to be recommended, but I think Mr. Ferriter would find that he would be unable to dispense with the repeating sounder should there be the least break-over from the pole-changer, or should there be any appreciable amount of power induction such as we experience on the coast wires. However, I have not had the opportunity to test this arrangement with the new quadruplexes, and it would not surprise me if, with the advantage of the holding coil and a variable condenser, it were not possible to do away with the repeating sounder, provided the closed key at the distant end is used for the short end.

Special Telegraph Line Construction.

The Postal Telegraph-Cable Company was required to change the location of its telegraph line in the locality of the Kensico Reservoir, in Westchester County, New York, which is to form part of the new waterworks system for New York City. The city gave a new location, where, by the construction of cement foundations and tall steel poles, the wires could be raised above the water of the reservoir itself.

Cement foundations and steel poles are required in order to carry the wires over long spans of from 300 to 600 feet, which means great pressure at times from sleet and wind. Accordingly, steel lattice poles were adopted. The angle irons which form the corners of these poles are extended downward a distance of seven feet from the bottom of the poles and are imbedded in the concrete base. The distance from the ground to the top of the pole is fifty-eight feet, twenty-three feet being the height of the cement base and thirty-five feet being the height of the iron lattice work. When the reservoir is flooded the water will reach within five feet of the top of the concrete base. The cost of constructing this extraordinary telegraph line is borne by the City of New York, the change having been made for its accommodation and the work is being done under the supervision of the plant department of the Postal Telegraph-Cable Company.

Reminiscences of Charles Minot.

Two interesting communications have been received from Mr. H. H. Atwater, of Brooklyn, N. Y., and Mr. Geo. M. Huntington, of New York, giving reminiscences of the late Charles Minot, general superintendent of the Erie Railroad, who was the author of the first telegraphic train order, the sending of which is to be commemorated by a monument to be erected at Harriman (formerly Turner), N. Y., next spring.

Mr. Atwater writes: "As near as I can remember, it was about 1855 or 1856 that I commenced to learn telegraphy in Burlington, Vt. Learning that the 'New York & Erie Railroad' was offering good positions for operators, my brother, who had learned in the same office and had accepted a position on the Erie at Waverly, N. Y., sent for me to join him, which I did, and was given a position as night operator at Corning, N. Y. This was in 1857. Later I was transferred to various offices where most needed, but mostly on the Susquehanna Division. I never worked in Mr. Minot's office.

"Mr. Minot had gotten up a Book of Rules containing forms to be used for the movement of trains by telegraph. Train dispatchers were appointed for each division to give orders as required, according to forms in the book, to trains entering upon their divisions. Geo. M. Huntington, an ex-military operator, and Chauncey Gardner were the train dispatchers of the Susquehanna Division. Mr. Minot was always very kind to operators. If applied to for a pass he would likely send a 'monthly.' The last office I was ordered to was at Susquehanna depot, of which office I was made manager. It being the junction of the Delaware and Susquehanna divisions, we were constantly receiving train orders from Port Jervis for trains on the Delaware Division and from Elmira for those on the Susquehanna. Higher positions on the road were almost always filled from the ranks of the telegraph. The operator at the next station eventually rose to the presidency of the road, while my own messenger boy, W. J. Murphy, in later years got to be general manager—the position formerly occupied by Mr. Minot.

"In 1863 I resigned my position and entered the service of the military telegraph."

Mr. Huntington writes as follows: "I was one of Mr. Minot's train dispatchers and could talk a week or two of the conditions and irregularities as well as the advantages and time economies of those old Erie days. Luther G. Tillotson was Mr. Minot's superintendent of telegraph. He and I were chums, but I went to California in 1850—the same year he was appointed superintendent—and did not return until 1853. We corresponded all those years. He told me all about the workings of the Erie and made me 'division operator' on the Erie as soon as I returned. But you need not search for any such things as train order blanks or prescribed rules for the running of trains under the Minot administration. It was after the coming of Gen. McCallum, who succeeded Mr. Minot as general superintendent of the Erie, that the thing was systematized to a certain extent, and it was one of McCallum's train orders ("Blank A") that was the cause of my being afterwards made superintendent of military railroads.

"General McCallum was a very stern looking man. Men said they would as soon be discharged as have him look at them. I was then train dispatcher of the Susquehanna Division at Owego.

"When a package of blanks 'A' first reached me, after reading one I said: 'The man who made that order didn't know a d—d thing about train dispatching.' Some one heard me and promptly reported my remark to Mr. McCallum. Next day I was sent for to come to Mr. McCallum's house. I went with fear and trembling, 'leaving all hope behind.' He was busy writing when I arrived, and told me to sit down. Later he picked up one of the blanks, turned to me and said: 'George (!) "I understand you said, "The man who made this order etc."' I said, 'Yes, sir.' 'Well,' said he, 'the trouble is you are right! I do not know much about it because it is in its infancy, and has to be to a certain extent experimented with. Now go on and criticize this order.'

"I showed him how under certain circumstances it would block the road. He said: 'Yes, I see, but the order is there and must be lived up to until I see a way to change it,' which he did not long afterwards, sending me the proofs of that and subsequent rules about train dispatching to criticize. He also did this when I was under him during the war.

"Tillotson was really a prime mover in the telegraph train dispatching business, but of course he was Mr. Minot's man. He originated the old code: '1, Wait a minute. 2, What time is it? 3. Have you any answer? 4. Where shall I go ahead,' etc.

"Here is a sample of the train orders of that early period (1853 or 1854). I was division operator of the Eastern Division at Port Jervis. A man named Westervelt was train dispatcher of that division. I seldom saw him except at breakfast at the Delaware House, when he would call to me across the table. 'Say, Huntington, if Blauvelt asks you anything from Suffern tell him yes, and sign my name to it!' That is all the order I ever knew him to give while I was at Port Jervis.

"Mr. Minot was not as particular as he should have been to obey his own rules. He used to come up over the road on a little engine we used to call the 'tea kettle,' hauling one coach, but he generally rode on the engine—running it himself. One time when I was train dispatcher of the Susquehanna Division at Elmira he came over the road 'wildcat.' I did not know he was coming beyond Susquehanna; in fact, I believe he originally intended to return from there. The Delaware division train dispatcher got him into Susquehanna all right. I had a work train on the double track between Great Bend and Binghamton with the right to use both tracks 'wildcat.'

"Mr. Minot after dining at Susquehanna jumped on his 'tea kettle,' and, without the formality of asking for orders, pulled out for Elmira, supposing that as it was double track it was safe enough. The consequence was when he got a little west of Great

Digitized by Google

Bend he bumped into the work train going east on the westbound track. Fortunately, it was a piece of straight track, and there was only a slight thump. The work train ran in at Kirkwood and let him by. Then he asked for orders. When he saw me at Elmira all he said was, 'How de do? I 'urt my 'ed,' and passed on. I was in California at the time of the episode at Turner and do not know if there is a man alive who was there. Harry Sweetser, who used to be a conductor on the Erie, and was afterwards a banker at Corry, Pa., was a favorite of Mr. Minot, and I think was with him at Turner at the time."

Report of Chief Signal Officer.

The report of Brigadier General James Allen, Chief Signal Officer, U. S. Army, for the fiscal year ended June 30, 1911, has been issued. It is a pamphlet of twenty-six pages and contains an excellent map of the U. S. Signal Corps telegraph and cable system in Alaska. The following interesting facts are taken from the report:

The Washington-Alaska military cable and telegraph system consists of 2,633 miles of submarine cable, 1,125.5 miles of land line and nine wireless stations.

During the year "this line" receipts aggregated $192,093. The "other line" receipts aggregated $16,633. Official messages to the value of $152,215 were transmitted. Telegraphic money transfers to the value of $69,472 were handled. Press rates have been materially reduced.

During the year the wireless plants at Fort Egbert and Fairbanks were changed from three kilowatts to five kilowatts, and a proportionate increase in efficiency has been realized. This increase in power has made it possible to maintain wireless communication between the two stations named and Circle City, Alaska.

The military telegraph system operated and maintained in the Philippine Islands comprises thirty-four miles of land line and ten offices. In addition to this there are four long-distance telephone lines with a total length of 106 miles and thirteen offices. There are now in operation in the Philippine Islands seven Army wireless stations.

One of the principal features of the army signal school at Fort Leavenworth, Kan., is the electrical laboratory, which is fitted up for the individual instruction of the student officers. At another part of the post there has been located a three-kilowatt wireless station, which communicates with Forts Omaha and Riley.

Post telephone systems were installed at Fort D. A. Russell, Wyo., and Fort Douglas, Utah. At the first-named post the entire system is underground, with the exception of a few outlying lines, and the equipment is the newest and most modern thus far used by the Signal Corps. A smaller telephone system embodying many of the features of the Fort D. A. Russell installation was provided for Fort Douglas, Utah.

At the close of the fiscal year there were 114 post telephone systems in satisfactory operation in the Army, of which fifty-one were extended central-energy systems.

As regards international wireless telegraphy, the report says the adherence of the United States to the Berlin treaty not having been confirmed by the Senate, this Government has no official standing in the International Bureau at Berne. In the official list of the Berne bureau of the radiotelegraph stations open for international traffic, which shows the land and ship stations conducted by the twenty-three countries and their colonies that have ratified the International Wireless Telegraph Convention of 1906, together with the calls and full instructions regarding the kind of communication which all stations are bound to recognize, no mention whatever is made of the wireless-telegraph stations of the United States.

Another international wireless conference is called to meet in London next June. The United States will be asked to send representatives, but they will not be able to take direct part in the conference owing to the fact that the United States is not a contracting party to the Berlin treaty.

The failure of the United States to adhere to the Berlin treaty, the report says, leads to great inconvenience to vessels bearing the United States flag, as it is only through courtesy or by some private arrangement that our ships can communicate with stations located in foreign countries.

There continues to be confusion in the transmission of wireless messages on the coasts of the United States which interferes with communication between various coast defenses and our ships at sea. The Army now has fifteen telegraph stations located at military posts in this country, nine stations in the territory of Alaska and one in the Philippine Islands.

Copying Behind in Alaska.

A good story is told in the *Yukon Valley News* of Tanana, Alaska, of an operator in that far-off place who was receiving a long message on the typewriter. Suddenly one of the types in the machine caught in the ribbon. The operator took out his pencil and punched two or three times at the letter. Finding he could not fix it that way he unhooked the carriage and took it off. Then he got the letter out; wound up the slack in the ribbon; replaced the carriage and started in to catch up with the sending operator who had all the while been pounding away without a stop. The sending operator was then about seventy words ahead of him. The only thing that kept the eyes of a young operator who was watching the proceedings from popping clear out on the floor was the fact that the operator did not take the trouble to put on a new ribbon.

Mr. C. E. Jones, manager of the Western Union Telegraph office at Zanesville, Ohio, in renewing his subscription writes: "I am certainly pleased that you kept the AGE coming right along. Keep it coming."

The Most Historic Spot in New York.

"The most historic spot in New York," says Mr. Walter P. Phillips in the *New York Times* of November 26, "as far as recent times go, is the room in the building at the corner of Liberty Street, the celebrated 145 Broadway, now occupied by Benedict Brothers. In the room corresponding to this store in a building long since demolished to make way for this new one, all the reports of the great events leading up to the civil war and during its progress were received over the wires of the American Telegraph Company and its connecting lines. Here were concentrated the wires of all the telegraph companies that were in existence in the days when Lincoln and Douglas were making their speeches and contesting the political ground of Illinois inch by inch. The great telegraph company in those days was the American presided over by Colonel E. S. Sanford and the late Marshall Lefferts, the gallant colonel of the Seventh Regiment."

Persons visiting the Benedict store are often seen to point to certain places on the floor and tell those who are with them that "here stood the table on which I received from Washington the news that Fort Sumter had been fired on," or that, "over there I received the news, four years later, that Richmond had fallen. I can hear the click of the instrument even now reminding me of Poe's reference to the bells whose voices a tale of misery foretells." Another visitor will say,"over in that corner Fred Catlin received the story of Lincoln's assassination, and right here to our left Ed. Schermerhorn copied the news of our disastrous defeat at Bull Run." The whole place is redolent of memories—the receipt of great stories of Union triumphs written by men who afterwards became famous as war correspondents, editors and artists, including Whitelaw Reid, the well-known "Agate," of the Cincinnati *Gazette*, Frank Millet perhaps the greatest of all American painters, Murat Halstead, and Henry J. Raymond. "After McClellan's victory at Antietam," mused another, "Lincoln issued his emancipation proclamation which shook the foundations of the world, one might say, and that was received, I remember, by Dixon F. Marks, night manager of the office. He was a southern man and he could not be kept away from the wire. This is the beginning of the end,' he observed as the perspiration rolled from his face and the tears came to his eyes. And so it went—one great history-making event after another."

"Right in the centre of the room here stood the table where the Boston wire came in," said another visitor," and it was worked by Walter P. Phillips with John E. Wright, the well-known inventor of printing telegraphs. Besides handling upward of four hundred messages every day, Jack and Walter disposed of all the cable business that there was. It was concentrated at New York from all directions and carefully sent to Boston and then on to Plaister Cove, N. S., whence it was relayed to Heart's Content, N. F., where the cable landed. There was very little of it, the rate at first being one hundred dollars for ten words or less, which later was changed to one dollar a letter." Another old operator will wander about the room, and pointing here and there will tell his friends that, "I sat at a telegraph desk not six inches from where my cane rests and took the first despatch that brought Grant into prominence. Halleck was ordering him to do all sorts of strange things in the southwest and the only response that he could elicit was the resignation of U. S. G., which he tendered again and again. We used to get some of those despatches from Cairo over the slim plant of an up-state corporation which had its offices upstairs in limited quarters. Generally messages for the War Department reached Washington from Cincinnati but wire troubles, of which there were many, often sent military telegrams around through New York. This company, up stairs, was the Western Union which, in 1866, absorbed the American Company and the United States Telegraph Company, the latter an opposition that had grown up during the later years of the war and which was headed by William Orton who became the president of the Western Union after the consolidation. That amalgamation of telegraph properties went on until 1887, when the thirty-third system was absorbed—the one that was exploited by the Baltimore and Ohio Railroad Company. Many interesting reminiscences are to be heard from men now grown rich and occupying high positions in commercial life. Some of the despatches that came over the Western Union from the West and were forwarded to Washington were relayed several times on the way from the Southwest to the capital. Wires were worked in short sections in those days and New York did not work further west than Troy and later to Albany. One or the other of these relaying points re-sent the messages received from New York and Boston as far west as Buffalo who in turn re-sent them to Cleveland or Cincinnati en route to the west and southwest. One of the Albany operators was Patrick B. Delany, while the Cincinnati force numbered among it George Kennan, the great authority on Russian affairs to-day, and the late Levi C. Weir, for many years president of the Adams Express Company, who began his business career in 1860 as a messenger in the telegraph office at Bridgeport, Conn. Another notable connected with the Cincinnati office, during the last days of the war, was Thomas A. Edison. He was a mere youth of seventeen or eighteen years and not a finished operator. But before he was twenty he had mastered the telegraphic art and ranked with Kennan, Weir and George Everett, three of the most conspicious telegraph operators west of New York.

In front of the old telegraph building passers-by would often assemble in small and respectful groups to view Professor Samuel F. B. Morse standing on the steps awaiting the coming of a Broadway omnibus. He was quite a hero, his in-

Digitized by Google

vention being less than quarter of a century old at that time and he a most distinguished looking man—tall and slender, with a long white beard that covered his face completely. To those of the present day he is a dim and almost nebulous figure like Webster, Clay, Calhoun, Irving, Rufus Choate and other men of their day, but in the early years of the civil war it was generally known that he had been a professor in the New York University, that he ranked with the best painters of his time, and that he had made the first Daguerre portrait, the predecessor of the ambrotype and carte de visite which have led to the present art of color photography. These early pictures were known all over the world as daguerreotypes in honor of the clever Frenchman with whom they originated. Though soon superseded by portraits simpler in process and much less costly of production they were the first sun pictures ever made and it is an interesting fact that Morse actually made these pictures, in New York, before the inventor of the process had succeeded in making any in France. Thus it was that thousands knew Professor Morse by sight and were glad to do him reverence whenever an opportunity offered. He died in 1872, one of the greatest men, if not the very greatest man, the world produced in the eighteenth century.

Distinguished Graduates from the Helena, Mont., Western Union Office.

Ten or fifteen years bring great changes in the personnel of large telegraph offices. Some of the members climb the ladder of business success; a few remain at the bottom and others drop out of the race entirely.

The Helena, Mont., office has an enviable record of graduating a large proportion of brilliant and capable men. An official of one of the telegraph companies recently informed us that it was a matter of great pleasure and satisfaction to him to look back to fifteen years ago to the make-up of the Helena, Western Union operating force. The following were members thereof: W. N. Fashbaugh, now engineer of traffic, Western Union Telegraph Company, New York; Charles H. Gaunt, general superintendent, Pacific Division, Western Union Telegraph Company, San Franscisco, Cal., Charles E. Davies, manager and supervisor of equipment, Great Northwestern Telegraph Company, Ottawa, Ont., J. W. Reed, superintendent, Western Union Telegraph Company, Philadelphia, Pa., James Swan, superintendent, Western Union Telegraph Company, Minneapolis, Minn., (lately deceased) W. P. S. Hawk, superintendent, Postal Telegraph-Cable Company, Chicago; J. G. Davies, manager, Western Union Telegraph Company, Vancouver, B. C., now in the real estate business at that place, and B. D. Snyder of the Postal Telegraph-Cable Company of Texas, Dallas, Tex. These constituted probably three fourths the entire force of the office at that time, and such a record for one office should be a matter of pride to all concerned. The remaining members of the force probably achieved prominence but no record of their subsequent careers is available.

Outside of Helena, Montana developed many notable men. Mr. L. Lemon, formerly at Glendive, Mont., is now division superintendent of the Postal Telegraph-Cable Company, New York.

In those days Mr. E. J. Nally was assistant superintendent of the Western Union covering Montana, with headquarters at Minneapolis, Minn. He is now vice-president and general manager of the Postal Telegraph-Cable Company, New York. Mr. Isaac McMichael was the superintendent of that division at the time. He later became vice-president and general manager of the Great Northwestern Telegraph Company at Toronto. Mr. R. H. Weiny was at the same time an electrician for the Northern Pacific in that section. He afterwards became a prominent electrical engineer and inventor. He died in New York in 1903. Several gentlemen who occupied positions in the railroad service in Montana now fill important official positions on various railroad systems in the country. Mr. L. Horton, Jr., who was also located at Helena, afterwards became superintendent of telegraph of the Philadelphia & Reading system in the east. He is the inventor of the Horton repeater.

A B C of the Telephone.

There are several excellent books on the telephone and its practice, but all men do not know the rudiments of the telephone. It is well, therefore, in order to gain an understanding of this instrument, as in everything else, to begin the study at the beginning. The telephone is no harder to know than any other electrical device and it becomes extremely fascinating on better acquaintance.

A B C of the Telephone is a good book for the student to start with. It explains the subject in non-technical language and the main facts connected with the telephone industry are stated in a clear and simple style. Although it is elementary in character it covers the whole subject of telephony so comprehensively and completely that after a careful study of the book the student will have a good working knowledge of the instrument and its many uses. The book is rendered particularly valuable by reason of the great many illustrations, each one of which tells a story. It has 350 pages and nearly 300 illustrations. The author of the work is Mr. James E. Homans and he is a master of the subject.

The price of this book is $1.00 per copy and copies can be obtained of TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

Many subscribers find some one special article in TELEGRAPH AND TELEPHONE AGE alone worth more to them than the subscription price of the paper which is $2 per year.

Digitized by Google

QUESTIONS TO BE ANSWERED.

[One of the most effective means of imparting information is to ask and answer questions, the value and power of this method being due to the fact that the information given in an answer is specific and direct. Asking questions for the student to answer for himself has proved to be an excellent means of education, as it promotes and encourages concentration of thought and investigation in order to arrive at the correct answer. There is a general demand for knowledge on the quadruplex, duplex, etc., and to aid in the acquirement of such knowledge we are extending our help to students by asking questions on these subjects in each issue of our journal, so that they may be encouraged in their studies by answering them. We use as our text book Maver, and Davis's "The Quadruplex," and students should have a copy of this book at hand in order to be able to give the answers. The questions are progressive and a careful reading of the book on the points under inquiry unfolds the answers. This method of acquiring technical knowledge is a fascinating one.]

REPEATERS.

(*Continued.*)

What advantage has the Toye repeater over the Milliken repeater?

What kind of instruments are used for the Toye repeater?

How many local batteries does the Toye repeater require and how many are necessary for the Milliken repeater?

What advantage does the Milliken repeater possess over other repeaters?

What are the resistances, or rheostats, used for in connection with the Toye repeater?

Name the two drawbacks of this repeater.

In the operation of this repeater what is the objection to keeping the batteries on constantly closed circuit?

Why did duplex and quadruplex apparatus displace automatic repeaters to some extent?

Describe how a duplex or quadruplex set repeats into another duplex or quadruplex set without the use of regular automatic repeaters.

What functions do the polar and neutral relays of the receiving set perform with reference to the transmitters of the opposite set?

Is it necessary that the No. 1 relay shall repeat into the No. 2 side of the opposite set, and the No. 2 relay into the No. 1 side?

What is the advantage of crossing from one side to the other?

Does the combination of a quadruplex and single circuit require a repeater?

At what point in the combined circuit are such repeaters located?

What is the name of one of the first repeaters used for this purpose?

Describe the operation of the Waterbury repeater and trace the circuits on the diagram on page 103.

What instrument does the neutral relay control at the repeating station?

Why does the Waterbury repeater work better in good weather than in stormy weather?

What is the effect of too much pull of the relay spring?

Could the repeating be done by one-half of a Milliken or Toye repeater instead of the Waterbury repeater?

How are quadruplex circuits divided between two firms?

In such cases where is the quadruplex set located?

What is the wire that runs from the quadruplex set to the broker office called?

Describe the Downer repeater shown on page 106.

What is the advantage of the Downer arrangement?

The Military Telegraphers' Pension Bill.

Mr. Charles P. Bruch, president of the Magnetic Club, New York, has received a communication relative to congressional action on the question of pensioning United States military telegraphers.

At the recent dinner of the club, president Bruch, in introducing Mr. David Homer Bates, secretary of the Society of the United States Military Telegraph Corps, referred to the matter as follows:

"At the outbreak of the war of the rebellion the inadequacy of the old-fashioned methods then used by the Signal Corps of the United States Army was soon realized, and the government promptly turned to the then new Morse telegraph for aid in directing the movements of its armies and the quick transmission of communications necessary in the conduct of the war. In a very short time—almost instantaneously—a large number of expert telegraphers were brought together and organized as a military telegraph corps, working under the direction of men commissioned by President Lincoln and Secretary of War Stanton as officers in the army of the United States.

"Although the invaluable services rendered by the military telegraphers were appreciated by Lincoln, Stanton and Grant, and by the army commanders, it is almost a crying shame that the government has neglected, so far, to give the members of the corps adequate recognition, and to express appreciation.

"But telegraph men, who can realize the dangers, hardships and difficulties surmounted by the military telegraphers during the war, fully appreciate their patriotism, self-sacrifice and devotion to duty, and the value of the work that was accomplished by them."

Telegraphers without exception—former and present—and thousands of others outside of the telegraph ranks who are familiar with the work of the war telegraphers, will hail with delight any favorable action that Congress may take in the matter, and all should unite in petitioning Congress to make suitable recognition of the work of the military telegraphers of the Civil War.

Mr. C. H. Mulford, manager of the Western Union Telegraph office at Newark, N. J., in renewing his subscription writes: "The AGE is just as much a necessity as my daily paper."

Rubber Insulation*.

Rubber, the unique vegetable product, for which no full substitute has ever been found, makes an unsurpassed dielectric when properly treated, by reason of its insulating qualities, extreme flexibility and imperviousness to moisture. Crude rubber varies widely in its characteristics and value, depending on its age, purity, and to some extent, the locality in which it is produced. It comes on the market mixed mainly with impurities, such as bark, clay and other foreign substances which are removed by washing and manipulation, resulting in a reduction in weight of from ten to fifty per cent., the finest Para rubber losing about eighteen per cent.

Rubber used as insulation is adulterated or degraded with various substances, so that the compound contains at most, only forty per cent of pure rubber, more usually about thirty per cent in the highest grade insulation down to five or ten per cent in the poorer rubber-covered wires, with no rubber in some cheap insulations which are called rubber.

Pure rubber is valueless for insulating purposes being too soft, hygroscopic, and readily oxidizable. When proper foreign substances to the extent of about sixty per cent or more, including about three per cent of sulphur, are added and the compound vulcanized by heating to from 250 to 300° F., the rubber is made stable, tough and durable, its value as a dielectric depending upon the details of this treatment. The exact temperature and duration of time necessary for vulcanizing depends on the grade of rubber, the ingredients used, and the percentage of sulphur added to the compound. The adulterants most commonly used for making the better grade rubber compounds are dry mineral matter or reclaimed rubber; the composition of the particular material used for compounding, may, in many cases, be left to the discretion of the manufacturer. Proper vulcanization is as important in producing high-grade insulation as the quality of the rubber used or the method of compounding. The amount of free sulphur left in the compound changes with oxidization. In no case should the free sulphur exceed about one per cent—the amount being determinable from the acetone extract—as an excess shortens the life of the rubber. Sulphur gives an indication of the quality of the rubber used, because much sulphur is required to vulcanize poor rubber and a large amount of combined sulphur may be taken as an indication that it was required in order to produce vulcanization.

The best rubber comes from South America, and is known as Para. Weber states that the reason for the inferiority of the African rubber is generally due to the presence of albuminous substances which are not removed by washing and which result in a brittle insulation; he also states that light will oxidize rubber, the more rapidly the less the degree of vulcanization. While a compound containing thirty to thirty-five per cent "old up-river" Para rubber is generally accepted as the requirement for insulation to be used in high-tension work; as a matter of fact, it is almost impossible for any chemist to ascertain, after vulcanization, just what the constituents of the insulation may be, and while any number of tests have been proposed, it is much better to rely on the standing and integrity of the manufacturer and his guarantees than to do business with unreliable firms, expecting to prove from an examination of the product furnished whether or not they are fulfilling contract specifications. While thirty per cent Para seems to insure high-grade insulation, it is beyond controversy that certain compounds containing less than thirty per cent Para give most satisfactory results in service, although they fail to meet some of the tests as to the requirements for the best insulation.

High-grade rubber is not only very elastic but possesses great tensile strength. If over-vulcanized it will break; if under-vulcanized it is not elastic, so that strength and elasticity are fair indications of its value as an insulating material. Those best informed agree that a new sample of thirty to thirty-five per cent Para compound properly vulcanized, should be capable of withstanding a tension of 700 to 800 pounds per square inch before breaking, and when stretched from two to three times its original length should return to within at least 125 per cent of its original length, when at a temperature of about 100° F. Although insulation containing appreciably less than thirty per cent of Para, with additional amounts of cheaper rubber, making a total of say, forty to fifty per cent may pass the tensile and elastic tests mentioned, such test usually indicates that the insulation contains only rubber, and no shoddy or bituminous products; but some authorities claim that a compound containing only Para will have considerably greater resistance to puncture than insulations containing the same proportion of Para with a proportion of inferior rubber in the materials used in compounding.

For the larger proportion of cables manufactured, namely, those used for low tension work, say under 5,000 volts, 30 per cent pure Para is unnecessary, the cheaper grades, as high-grade Ceylon, Malay or African Lapori; for example, giving very satisfactory results for this particular class of low-voltage work, while even the rubber produced from the Mexican guayule is used for the insulation of telephone wires.

The quality and life of rubber insulation has heretofore generally been considered as indicated by the amount of resinous or extractive matter it contained. A high percentage of resinous matter, say fifteen to twenty per cent, was taken to indicate a cheaper and poorer grade of rubber, whereas a low percentage, one to two per cent, was assumed to be found only in the best grade of Para, which comes from South America.

Owing to some unknown cause, the amount of

*From "High-Tension Underground Electric Cables," by Henry Floy.

Digitized by Google

extractive matter increases largely in the working and mastication of the gum, there being still further increase during vulcanization. The amount of resinous matter is determined by digesting the gum in acetone, which dissolves out the extractive matter. Standard practice specifies that the acetone extraction shall be carried on for five hours in a Soxhlet extractor, as improved by Dr. C. O. Weber. It is important that care be taken in making the tests, not only that proper conditions should be observed, but that the duration of the test is as specified, otherwise the results may vary widely. As an example of this, it may be stated that in a given instance, a forty per cent Para rubber compound, such as used by the United States Government, if heated for a period of about twelve hours, to 220° F. in a drying oven prior to being treated with acetone resulted in increasing the weight of the acetone extract from two per cent to eight and one-quarter per cent. The greater part of this increase took place during the first few hours of heating. In the same way, the longer an acetone test is continued the larger the percentage of extract obtained, although by far the greater proportion is given off during the first five hours. From this, the necessity of properly conducting and carefully timing the length of the test will be recognized. The rubber to be tested should first be dried over calcium chloride in a vacuum at slightly elevated temperature, and then treated with acetone in the extractor.

It should be understood that the acetone test determines the quality of the rubber compound, so that the usual maximum percentage limit of five per cent, for example, must be raised provided it is intended that the manufacturer shall be permitted to introduce other substances in the adulterant used for compounding, which in themselves contain extractive matter. If it is clearly stated in the specifications that only Para rubber to a definite percentage is to be used and that the remainder of the compound is to be of some other material than rubber, then the five per cent should not be exceeded.

There exists a wide difference of opinion and practice as to the proper limit of extractive matter that should be permitted in a high-grade compound. Some specifications require that the acetone extract should not exceed three and one-half per cent by weight, of the gum in the compound, while the more usual specification and that issued by the rubber manufacturers, sets the upper limit of extractive matter, as five per cent by weight, of the total compound that is, in a thirty per cent Para compound, the weight of extractive matter shall not exceed about seventeen per cent of the weight of the gum. More recent experience and research has shown that some African rubber gum may contain as low as two to three per cent of extractive matter, while some high-grade Para, giving excellent results in service, will contain over four per cent of such matter. With these wide variations and with the knowledge that by proper treatment the amount of acetone in a compound can be reduced to even two or three per cent if necessary, the value of the acetone test is being discredited and abandoned by many engineers—for example, the Specifications for Electric Wires and Cables, issued by the Navy Department, omit all acetone tests whatever, depending upon other tests entirely to determine the value of the compound.

The introduction into rubber compounds of waxy ingredients such as paraffine, for the purpose of increasing megohm measurements, etc., should be limited; a small amount, say three to four per cent of the weight of the rubber gum will not prove injurious.

In America the rubber compound is applied to a conductor in either of two ways:

(a) By passing the conductor through a press similar to a lead machine and applying the compound in a plastic state at relatively high temperature as a seamless tube, as the conductor passes out of the machine. This is called "spewing," and is used more particularly with smaller sized conductors.

(b) By applying the insulation in a longitudinal strip by means of a machine which folds the compound around the conductor and unites the edges in a continuous and almost invisible seam. As judged from practical results, the strip insulation seems about as satisfactory and reliable as the seamless insulation, and it has the further advantage of keeping the conductor properly centered and having imperfections in one layer covered by additional layers.

In Europe the insulation of conductors by winding with rubber tape has been successfully accomplished. This method should be expected to result in a more uniform dielectric capable of withstanding greater potential stress, for a given thickness, than when applied by "spewing" or in strips.

With any method of applying the compound, a braid or tape over all is employed t obetter hold the compound in position and prevent its swelling and becoming porous during vulcanization; such tape has no particular value as a dielectric.

Rubber insulated underground cables are usually covered with a lead sheath both for mechanical protection and to guard against attacks from oils, acids or oxidization. The substitution of a fibrous covering served with a bituminous compound or something of that sort, has been attempted in place of the lead sheath and is said to be found as satisfactory under some conditions particularly where electrolysis cannot be avoided, although such substitution is ordinarily based primarily on considerations of cost.

When completed the rubber insulated cable is the most flexible of all, and should be capable of being bent on a radius equal to five times its diameter, bent similarly in a reverse direction; have the process repeated three times and then withstand puncture and ohmic tests.

Proposed Monument to James D. Reid.

At the fall dinner of the Magnetic Club in New York, November 15, president C. P. Bruch called attention to the fact that the grave of the late James Douglas Reid, in Mt. Hope Cemetery, Rochester, N. Y., is marked only by a very simple stone bearing his name. He pointed out that Mr. Reid was the first superintendent of telegraph; the employer of many boys who in later years attained great success and prominence in the telegraph and other lines of business; the first employer of women in the telegraph service; that he was a friend and contemporary of Morse; one of the organizers and first president of the Telegraphers' Mutual Benefit Association, and one of the organizers of the Old Time Telegraphers' and Historical Association, and at one time its president; that he was actively interested in and identified with many other organizations and movements for the benefit of telegraphers, and with various charitable and religious bodies; that he was the author of the only history of the telegraph as yet published; and that he was the founder and editor of the first electrical paper in the world. Mr. Bruch suggested that Mr. Reid's services to the telegraph, his friendship for telegraphers, his helpfulness to all with whom he came in contact, and his gentle, lovable character that endeared him to everyone who knew him, entitled him to a more suitable and lasting monument than now marks his grave, and expressed the opinion that it is the duty of the telegraph associations, and of the telegraph fraternity at large, to co-operate in erecting a monument to his memory.

Pursuant to this suggestion, the meeting adopted a resolution directing the officers of the Magnetic Club to communicate with the officers of the various telegraph associations, requesting the co-operation of those associations in a movement to raise the necessary funds and erect a suitable monument, or other form of memorial.

In accordance with this resolution a letter embodying these facts and suggestions has been sent by Mr. Bruch to the presidents of the various telegraph organizations as follows: Mr. Belvidere Brooks, Telegraphers' Mutual Benefit Association, New York; Mr. A. G. Saylor, Serial Building Loan & Savings Institution, New York; Hon. W. S. Jordan, Old Time Telegraphers' and Historical Association, Jacksonville, Fla.; Col. Wm. Bender Wilson, Society of the United States Military Telegraph Corps, Holmesburg, Philadelphia, Pa.; Mr. R. J. Marrin, New York Telegraphers' Aid Society, New York; Mr. W. J. Dealy, Gold & Stock Life Insurance Association, New York; Mr. J. B. Van Every, The Morse Club, New York; Mr. G. A. Cellar, Association of Railway Telegraph Superintendents, Pittsburg, Pa., and Mr. W. C. Daviet, The Magnetic Club of Atlanta, Atlanta, Ga.

Mr. Bruch suggested that each association cooperating appoint two of its members residing in (or in the vicinity of) New York to serve as members of a committee to organize and carry on the work of collecting funds and arranging for the design, construction and dedication of a monument, or other memorial, if for any reason it is found to be impracticable to erect a monument.

Col. Wm. Bender Wilson, Holmesburg, Philadelphia, Pa., president of the Society of the United States Military Telegraph Corps, has appointed Messrs. David Homer Bates of New York, and Charles Almerin Tinker, of Brooklyn, N. Y., to represent the society on the joint committee to arrange for a memorial to J. D. Reid.

Messrs. Thomas M. Brennan and Robt. J. Marrin have been appointed to represent the New York Telegraphers' Aid Society on the committee.

New York Telegraphers' Aid Society.

President R. J. Marrin extends his sincere thanks to the members of the Aid Society and their friends, also to the officials of the Western Union and Postal Telegraph-Cable companies, including Mr. J. F. Zeiss, and the officers, chairmen and members of the various committees, who labored so hard to make the annual entertainment and reception for the benefit of the Relief Fund such a great success financially, socially and otherwise.

He also thanks the New York and Brooklyn newspapers which devoted so much space in their columns to the society's interests. "This," he says, "is one of the finest annual affairs held at Terrace Garden, and reflects great credit on the members of the New York Telegraphers' Aid Society.

"It is a pleasure for me, I can assure you," he adds, "to labor in your behalf when such a vast assemblage turns out to crown my efforts, and it is my heartfelt wish that our members will increase to such proportions that Madison Square Garden will be required to hold us in the near future."

Mr. Clarence H. Mackay, president of the Postal Telegraph-Cable Company, New York, has contributed, through Mr. E. J. Nally, vice-president and general manager, $100 toward the relief fund of the New York Telegraphers' Aid Society.

Novel Jail.—The jail of Gerlach, Cal., consists of a telegraph pole. Offenders are chained to the pole and left to serve their terms of imprisonment (?). The pole is marked "Gerlach City Jail." Gerlach is to have a new portable steel jail, however, to take the place of the open-air affair.

Mr. Frank N. Dowler, many years ago identified with the telegraph service but of late years a railroad official in New York, in renewing his subscription, writes: "I take great pleasure in sending you herewith my check for TELEGRAPH AND TELEPHONE AGE for 1912. I also deem it a pleasure to recommend your paper to any persons I think ought to have their names on your subscription list."

KERITE

INSULATED WIRES and CABLES

DEPENDABLE

Kerite Cables installed upward of 35 years ago, and exposed to deteriorating influences, are giving perfect service to-day.

EFFICIENT

Kerite does not rely upon the rubber in its composition for insulating efficiency. Kerite itself is a compound having superior insulating qualities.

SERVICE

A half century of successful service has demonstrated that Kerite possesses the essential qualities of safety, reliability and economy to an exceptional degree.

Kerite Insulated Wire and Cable Co.

The Railroad.

Mr. C. H. Hubbell has been appointed superintendent of telegraph of the Chicago, Rock Island & Pacific Railway, Chicago, vice J. G. Jennings, deceased.

Telephone Train Dispatching on the Canadian Pacific.—Mr. James Kent, manager of the Canadian Pacific Telegraphs, Montreal, Can., states that there is no truth in the dispatch from St. John, N. B., that the Canadian Pacific Railway will abandon the telephone dispatching system at present established on any part of its lines. The system is said to have proved such an unqualified success in every part of the four thousand miles now equipped that a number of additional telephone circuits will be installed during the coming year.

Lake Shore to Install Telephones for Message Service.—The Lake Shore and Michigan Southern Railroad, E. C. Keenan, superintendent of telegraph, Cleveland, Ohio, is preparing to install telephones in order to open message circuits on two of its divisions, and has recently placed an order with the Western Electric Company for the apparatus. The circuits will extend from Toledo, Ohio, to Elkhart, Ind., a distance of approximately 145 miles, and from Fort Wayne, Ind., to Jackson, Mich., a distance of about 100 miles. Thirty-three selector stations will be equipped on the first named division and twenty-two on the latter.

C. J. Steinel, Superintendent of Telegraph, San Pedro, Los Angeles and Salt Lake Railroad.

Mr. Conrad J. Steinel, whose appointment as superintendent of telegraph of the San Pedro, Los Angeles and Salt Lake Railroad at Los Angeles, Cal., was announced in our issue for December 1, was born in Milwaukee, Wis., July 3, 1869. On September 1, 1882, he began his telegraphic career as messenger for the Western Union Telegraph Company at St. Joseph, Mo. Later he took up railroad work and became an operator on the Burlington road and afterwards train dispatcher. He was train dispatcher on the San Pedro, Los Angeles and Salt Lake Railroad for a time, and then received the appointment as chief clerk to the late Isaac T. Dyer, superintendent of telegraph of that road, to fill which position Mr. Steinel has recently been appointed.

Mr. Pettengill on the Railway Situation.

Brief reference was made in our issue for December 1 to the banquet of the Railway Business Association in New York at which Mr. H. J. Pettengill, president Southwestern Telegraph and Telephone Company, Dallas, Tex., made an address. Mr. Pettengill represented the Commercial Secretaries and Business Men's Association of Texas. In Governor Colquitt's first message to the Texas legislature that official, Mr. Pettengill said, recommended that no law be passed that would frighten away capital or jeopardize the investment of honest money: that the rights of property be recognized whether owned by the people of Texas or of other states. Not a single restrictive law was passed at the last session.

Mr. Pettengill and the association he represented were in entire accord with the aim of the Railway Business Association which is the conciliation of the railroads and the people and to awaken the country to the study of the railway situation.

Telephone Dispatching on Buffalo, Rochester & Pittsburgh.—The Buffalo, Rochester & Pittsburgh Railroad has placed an order with the Western Electric Company for equipment to be used in connection with the introduction of train dispatching by telephone on a part of its system. Two separate train wire circuits will be installed. One will extend from Rochester to East Salamanca, N. Y., a distance of approximately 110 miles, with the dispatcher at Rochester, and the other from Buffalo, N. Y., to East Salamanca, a distance of approximately 65 miles, with the dispatcher at the latter place. Both of these division train wires will enter East Salamanca and provision will be made for establishing through connections between Buffalo and Rochester. A special feature consists of a box to be placed outside of twenty way station buildings, containing equipment which will enable a train crew to get in touch with the dispatcher when the way station is closed at night, and every train on each division will carry a portable telephone set which need merely be connected to the box equipment in order to communicate with the dispatcher.

Our Subscription Contest.

As the time for the closing of the subscription contest draws nigh the activity of our agents is becoming manifest in the large number of new subscriptions sent in. There is time yet for any five of our agents to capture the prizes.

The contest will close at 3 p. m. Thursday, December 21, so that checks can be mailed to the winners of the prizes the same afternoon.

The terms of the contest were given in our issue for September 1. Five prizes, amounting to $100, were offered those of our regularly appointed agents sending in the largest number of new subscriptions during September, October and November and up to December 21. The prizes are as follows: First, $50; second, $25; third, $15, and the fourth and fifth, $5 each. The contest is limited to new subscriptions and renewals only. The total amount of cash received from each agent on this account will decide the contest and in the event of a tie on any one prize, the prize will be divided.

Money must accompany all orders for subscriptions. Many of our agents secure subscriptions or renewals for from two to ten years. In cases like this a five or ten years' subscription will count as five or ten yearly subscribers, as the case may be.

The Economies of Telephone Train Dispatching.

At the joint meeting in Chicago, November 23 and 24 of the Eastern and Western divisions of the Association of Railway Telegraph Superintendents, the discussion of the subject of train operation by telephone brought out some interesting and valuable facts concerning the economies of the method.

Mr. G. A. Cellar, superintendent of telegraph of Pennsylvania Lines West of Pittsburgh, and president of the Association, stated that where telephone dispatching has shown a saving in number of dispatchers and in operators' salaries such economy has been distinctly offset by the increased cost of operation and maintenance of the telephone lines.

Mr. W. C. Walstrum, of the Norfolk & Western, Roanoke, Va., stated that it has cost his road $1.01 per annum per road mile to maintain the telephones, including the wages of maintainers, cost of batteries, etc. They put extra men on who take care of the instruments and line, but not of the poles. A supervisor has charge of all telephone work at a salary of $110 per month. One of the economies mentioned by Mr. Walstrum was that one man at one of his stations is able to handle three dispatching districts by telephone.

Mr. E. A. Chenery, of the Missouri Pacific, St. Louis, Mo., stated that his road has one maintainer on 155 miles who gets $90 per month and expenses while away.

Mr. C. S. Rhoads, of the Cleveland, Cincinnati, St. Louis & Chicago, Indianapolis, Ind., said his 1400 miles of telephone lines have been in service nearly three years, resulting in a substantial decrease in dispatchers, salaries and offices, compared with telegraph operation. Besides saving labor, he declared telephone operation to be much safer, since the sending operator is required to write down the orders as he transmits them, assuring a speed at which the receiving station can follow. The speaker also noted the possibility of simplexing telephone dispatching lines for through Morse operation, gaining a number of additional telegraph circuits. By inter-operation with friendly roads it is thus possible to establish circuits which may become useful in establishing communication around fallen line sections, accidents to poles, etc. Mr. Rhoads said his 1400 miles of lines are taken care of by three inspectors, who receive $65 a month, with unlimited expense accounts, and have the aid of twenty-one linemen. Twenty-one motor cars are in use by these men.

Mr. W. F. Williams, of the Seaboard Air Line, Portsmouth, Va., asserted that the saving effected by telephone operation cannot be expressed on a monetary basis. The figures for his own 1100 miles of lines, he said show a gain of 11 per cent. in train time, in spite of an increase of 14 per cent. in track density.

Mr. J. J. Ross, of the Michigan Central Railroad, Detroit, Mich., declared that the presence of simplexing apparatus on his telephone circuits seemed to clear the lines by discharging static accumulations. Mr. F. H. Van Etten, of the Chicago, Terre Haute & Southern, also recounted his experience.

Electric Club of New England.

The Electric Club of New England held its fourth meeting of the fall series in the Auditorium of the Boston Edison Electric Light Company, on November 23. The efforts of Mr. W. S. Barker, district plant superintendent, Western Union Telegraph Company, in behalf of the club in securing such excellent quarters and the generosity of the Edison Company in the matter were made the subject of resolutions expressing the thanks of the club.

The chief speaker was Mr. A. C. Kaufman, commercial agent, New York. He gave a most forceful outline of the benefits of the three column organization, dwelling particularly on the commercial line of endeavor.

District plant superintendent W. S. Barker gave a brief talk showing the value of club meetings to all concerned in developing new ideas and opening the way to new and better understanding of the various lines of endeavor.

District commercial superintendent C. F. Ames gave a talk upon commercial matters showing how traffic and plant employes as well as commercial can be business getters while strictly attending to their own lines of specialized endeavor.

Manager O. A. Conner of the Boston office followed Mr. Ames, adding a few original observations and Mr. L. D. Wilbourn, district traffic superintendent, spoke on general matters of interest.

Mr. Kaufman was then asked by chief equipment man, Mr. R. W. Hall, to give his views of tickers and clocks as adjuncts to regular service, which he did. Other speakers were Mr. Totman, district supervisor of equipment; Mr. J. B. Rex, general traffic chief; Mr. W. G. Wetmore, district superintendent of traffic, Mr. Cook, of the Gold & Stock telegraph department; Mr. A. J. Thompson, assistant wire chief; Mr. Edward Holden, Mr. William Ryan and C. F. Dolan.

Cash Registers in Telegraph Offices.—The New Zealand post office department, which controls the telegraph service, has installed in the telegraph department of the Wellington general post office a cash register machine for recording and keeping separate the totals of all kinds of telegrams.

The Edison Storage Battery.—Mr. Thomas A. Edison recently celebrated the completion of his storage battery experimentation by entertaining 200 members of the classes of electrical engineering from the Brooklyn Navy Yard, at this factory in Orange, N. J. He spent nine years in perfecting the battery.

THE SECRET of SUCCESS IS SERVICE

See this space in next issue

UNITED STATES ELECTRIC COMPANY
NEW YORK CHICAGO

New Book on Telephony.

A new book entitled "Modern American Telephony in All Its Branches," by Arthur Bessey Smith, will be ready for delivery in November. It will contain over 800 pages and nearly 600 illustrations, and will be the most complete and up-to-date work on the subject. The price will be $2.00 per copy. Address TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

THE NIGHT LETTER TELEGRAM

HAS MADE

A GOOD WORD COUNTER

a practical necessity for every telegrapher. One of these devices is now as essential a part of his equipment as a typewriter. On account of the increased demand for the HUDSON WORD REGISTER, which is the only counter on the market suitable for this class of work, the manufacturers have been able to reduce the price from $5.00 to $3.00 each.

Mailed to any address upon receipt of price. Remit by express or post office money order to

Official Diagrams of the Postal Telegraph-Cable Company's Apparatus and Rules Governing the Construction and Repair of Lines

This volume contains 134 pages, including 105 full-page diagrams; size 7 x 4½ inches; price 50 cents.

Fourteen pages are devoted to rules governing the construction and repair of telegraph lines; and four to the subject of standard tools. Submarine cable splices, underground cable splices, single-wire joints and aerial cable splices are also fully treated. Under the general head of Rules for Wiring Offices and Cable Boxes, the subjects of the terminal office, intermediate offices, submarine and underground cables, aerial cables, call circuits and call boxes, leased wire offices, branch offices, miscellaneous, are fully given. Then come rules for the care of motors and generators, explanation of and rules for the care of the Callaud battery, rules for the care of the Leclanche battery and resistance coils, following which is the table of Size and Insulation of Wire Cable for interior use, and that of Wire Gauges.

The nominal price for so large, important and complete a work, embellished with so many first class plates, made especially for it, makes the book a valuable acquisition, indispensable to every telegraph and electrical student. The book contains diagrams of the Phantoplex system, the latest development in the telegraph art. All of the engravings are made from the official blue-prints of the Postal company, and are therefore absolutely correct, and have been produced under the direct supervision of John F. Skirrow, associate electrical engineer.

All orders should be addressed to

Boston Meeting of Western Union Office Managers of Fifth District.

On December 6 a meeting of the office managers of the fifth district Eastern Division of the Western Union Telegraph Company, was held in Boston, and was attended by ninety office managers and commercial employes.

District commercial superintendent C. F. Ames presided and made the opening address. In connection with other matters he recommended that the managers who were not already subscribers to TELEGRAPH AND TELEPHONE AGE, secure copies which were on hand for distribution, and advised that they subscribe for it as there were many items in each edition which would be very helpful to them.

He was followed by district commercial manager Pearson, who gave an interesting talk on "New Ideas" in telegraph solicitations. District commercial manager Chase read a paper covering "Office Management;" Inspector Fitzgibbon spoke on "Messenger Improvements," and Mr. Daniel Sargent, in charge of the telephone arrangement for the district, explained the telephone combination arrangements now in effect in the district. District supervisor of traffic Sollers followed with a paper on "Co-operation of Managers as Applied to Traffic."

At the afternoon session manager Dickinson of Worcester, Mass., made an address on "Office Management," and was followed by manager Shaw of Rutland, Vt., on the subject of "Door-to-Door Solicitation." Mrs. A. L. Faulkner, manager, Holyoke, Mass., gave an interesting paper on "Door-to-Door Solicitation and Distribution of Blanks." Manager Mennealy, of Lewiston, Me., spoke on the subject of "Solicitation at a One-Man Office." Mrs. M. A. Gustavison, Chelsea, Mass., followed with an address on "Solicitation by Lady Managers."

Manager Kelley, of Springfield, Mass., in his paper on "Courtesy" brought out some very good points, and district commercial manager Orr spoke on the subject of "Harmony."

District traffic supervisor Wetmore spoke on the subject of "Commercial and Traffic Department Matters," and general traffic chief J. B. Rex, of the Boston office, read a paper on the "Co-operation of the Boston operating Department with the Field Officers." He was followed by chief solicitor Boothby and solicitor Patterson of the Boston office, who spoke on "Door-to-Door Solicitation," and manager Flanagan of Bangor, Me., gave a short talk on the same subject.

The afternoon session ended with a stereopticon lecture given by district commercial manager Johnson, showing the various means used by the commercial department in getting new business.

A dinner was served at 7 p. m., after which division commercial superintendent E. M. Mulford of New York, gave a very interesting talk on commercial matters pertaining to the division. Commercial agent A. C. Kaufman delivered a fine address on the commercial department's various services, and the getting and retention of telegraph business. District traffic superintendent L. D. Wilbourn gave some helpful suggestions to the commercial department in the matter of handling traffic.

Mr. L. J. Shay, manager of the leased wire service, New England Telephone and Telegraph Company, explained the work of the combination telegraph and telephone offices and telephone matters as pertaining to the telegraph in the district, and was followed by district plant superintendent W. S. Barker, who gave some interesting statistics in a witty address relating to plant matters.

Manager O. A. Conner, of the Boston office, talked on general commercial matters.

In addition to those named the following managers were present: A. D. Davidson, Brockton, Mass.; T. F. Breslin, Fall River, Mass.; F. D. Byrne, Duxbury, Mass.; W. F. McClure, New Bedford, Mass.; W. H. Boyers, Taunton, Mass.; Miss K. G. Leary, Pawtucket, R. I.; P. S. Carey, Providence, R. I.; H. G. Haddon, Woods Hole, Mass.; A. J. Damien, Bellows Falls, Vt.; E. J. Burke, Burlington, Vt.; M. J. Walshe, White River Jct., Vt.; G. E. Marshall, Middlebury, Vt.; R. T. Leddin, Montpelier, Vt.; C. L. Bingham, St. Albans, Vt.; G. H. Batho, No. Adams, Mass.; E. Baudry, Chicopee Falls, Mass.; E. I. Herbert, Augusta, Me.; M. F. Foley, Bar Harbor, Me.; G. H. Cushing, Eastport, Me.; H. H. White, Portland, Me.; W. P. Walsh, Rockland, Me.; Miss E. E. Clay, Waterville, Me.; Miss E. M. Sanborn, Bath, Me.; M. Petit, Calais, Me.; C. E. Somerville, St. Johnsbury, Vt.; J. A. Bardwell, Brattleboro, Vt.; C. J. Abott, Manchester, N. H.; Miss E. G. Wilson, Concord, N. H.; G. H. Wright, Nashua, N. H.; E. M. Fisher, Portsmouth, N. H.; A. D. Allen, Newburyport, Mass.; J. H. Lang, Lynn, Mass.; J. C. Bonner, Gloucester, Mass.; Z. I. Bossonnette, Lowell, Mass.; J. F. Hanrahan, Lawrence, Mass.; C. A. Pearson, Haverhill, Mass.; R M. Bucknam, Waltham, Mass.; Miss M. E. Preston, Fitchburg, Mass.; Mrs. E. E. Dwyer, So. Framingham, Mass.; H. B. Simons, Cambridge, Mass.; J. E. Stroy, Salem, Mass.; F. W. Mihills, Wellesley, Mass.; Miss M. E. Knight, Beverly, Mass.; H. P. Goldthwaite, Dover, N. H.; R. I. Davidson, Peabody, Mass.

New York's Fire Alarm System.—In an article in *McClure's Magazine* for December, under the heading "The Conflagration Hazard in New York," Mr. Arthur E. McFarlane arraigns severely the New York fire alarm system. He says it is "the worst in the United States." It was installed in 1869 and has not been modernized, ninety per cent. of the antiquated equipment being still in use. "It is fundamentally wrong in design," he says, "and is in bad physical condition."

Postal Telegraph-Cable Company's New Business Office at Boston, Mass.

BY J. P. O'DONOHUE, DIVISION ELECTRICAL ENGINEER, POSTAL TELEGRAPH-CABLE COMPANY, NEW YORK.

The Postal Telegraph-Cable Company has recently enlarged and remodelled its main business office at Boston, Mass., and it now occupies the entire ground floor and basement space of the building at 100 State Street.

The office is thoroughly up to date in equipment and its general appearance is unusually attractive. The ceramic tile flooring in the customer's lobby sets off the beautiful white marble counter to advantage. All the woodwork is finished in mahogany and the office furniture has been carefully selected to harmonize. Ornamental railings, three feet high, fitted with diamond-shaped spindles, are used to separate the different departments instead of the usual high partitions. The effect of this departure

VIEW OF POSTAL OFFICE, BOSTON, MASS.

in office fittings is quite noticeable in the ventilation and natural lighting. The manager's offices are located in the westerly end of the building, with the cashier's department at the easterly end and the call-circuit and delivery departments in the rear. The delivery department is connected with the operating room in the India Building, 84 State St., by two pneumatic tubes. There is also a tube connection between this department and the Commercial Cable Company's main office in the adjoining building.

The call-circuit and time-service equipment have been entirely rearranged and many new features have been introduced which greatly expedite the service.

In the basement are located the motor blowers for pneumatic tubes, supply room, messenger's uniform room and a messenger's lunch room. A shower bath for the boys has been provided, as well as other comforts for them and for the clerical force.

The staff of the Boston office consists of C. A. Richardson, superintendent; F. B. Travis, manager; J. D. McDonald, chief operator; Daniel Carter, traffic chief; L. W. Hoyt and H. L. Vincent, day wire chiefs; J. J. Coen, quadruplex chief; C. W. Lanfair, night wire chief; P. J. Farrell, night traffic chief, and C. B. Parmenter, all-night chief.

The Turner Monument Dedication Postponed.

Owing to the lateness of the season it has been decided to postpone the dedication exercises of the Turner monument until the end of April or the first part of May next year. This action was taken on account of the ground at Harriman (Turner), N. Y., being covered with snow and will likely remain so all winter.

Superintendent C. T. Ford, of the Harriman Estate, of Central Valley, N. Y., who is doing the cutting of the monument has about finished his work and reports having secured an excellent stone. The bronze tablet has also been completed by the Gorham Manufacturing Company at Providence, R. I., and now awaits shipping instructions. Mr. George H. Mills, manager of the Postal Telegraph-Cable Company at Providence, was asked by the committee having the matter in charge to pass upon the tablet. He did so and pronounces it an excellent piece of work. On his suggestion certain changes were made by the Gorham Company in the length of dashes and spaces in the Morse characters on the tablet which give satisfactory results in this regard.

It is announced that Mr. Andrew Carnegie will be present at the unveiling ceremonies, besides other distinguished persons.

It is the general opinion that the committee acted wisely in postponing the date of the unveiling as the wintry weather would likely interfere with the comfort of those who attended and prevent others from making the journey.

The contributions received up to date toward the monument fund are as follows: Previously acknowledged, $1,716.99; David Homer Bates, New York, $10.00. Total, $1,726.99

Improvement in Telephone Wiring.

The Antwerp Telephone Company, Antwerp, Belgium, has recently put on the market a new type of conductor with a view to simplifying and cheapening house telephone wiring.

Two high grade, rubber insulated wires are passed side by side through the sheathing machine with the result that both are lead covered and are, further, mechanically connected by a thin lead web.

To erect the duplex wiring, it is only necessary to drive brads through the webbing. When it is desired to separate the conductors for connecting or other purposes, it is only necessary to cut through the web plate with a roller knife. Each conductor then remains fully lead-sheathed right up to the terminal to which it is attached. Triple and quadruple conductors are arranged in a similar manner.

LETTERS FROM OUR AGENTS.

ATLANTA, GA., WESTERN UNION.

The first meeting of the season of the Electrical Class was held Friday evening, November 24, with an attendance of twenty-five. The course in technical telegraphy which began in TELEGRAPH AND TELEPHONE AGE October 16, was adopted, and Prof. H. P. Wood, of the Georgia Technical High School, was chosen to teach the class. Chief operator B. F. Ragsdale gave the class an interesting talk, in which he explained the benefits to be derived from such a course, and it was evident throughout the meeting that he intends to keep the class interested and enthusiastic in the work.

The Atlanta office is one of the most modern and up to date in the country. Every effort is put forth by the officials to make the operators comfortable. Commodious rest rooms, well furnished with conveniences, including shower baths, etc., are provided.

The operating force, comprising one hundred and seventy-five operators, as a whole are happy and contented, appreciating fully the liberality of the company in providing for their comfort in every way possible, and appear anxious to carry out the wishes of superintendent E. E. Williams to make the Atlanta office a model in every way. Our record of nearly one million messages per month bespeaks their appreciation.

Mrs. M. P. Norman, the efficient teacher of our telegraph class, may well be proud of her pupils, thirty in number, all of whom are progressing rapidly. Some of her students have qualified for branch office positions and are filling them very creditably. Mrs. Norman is a first-class operator, and works one of our fastest circuits.

NEW YORK POSTAL.

Andrew S. Hunter, aged 40 years, manager of the 30 Church Street office of the Postal Telegraph-Cable Company, New York, died in Brooklyn on December 4.

Mr. R. Jacobs has been appointed manager of the office at 145 East Twenty-third Street.

Mr. E. B. Stanley, formerly manager at 944 Broadway, has been transferred to the 83 Gold Street office, vice W. Scrivens, who has gone to the 944 Broadway office.

Miss A. G. Whalen has been transferred from the 145 East Twenty-third Street office to take charge of the Brevoort Hotel branch office.

Hugh Moffitt, an operator at 253 Broadway, died December 1.

OMAHA WESTERN UNION.—The following officials visited Omaha recently on general company business: Mr. W. C. Titley, division plant superintendent, and Mr. B. L. Brooks, division traffic superintendent, Denver, Col.; Mr. J. J. Welch, district traffic superintendent, Chicago, Ill.

Mr. B. P. Meyers, chief operator at Denver paid Omaha a visit on his way to Kansas City.

C. B. Horton and W. Salisbury, district superintendents, and J. P. Barnhart have returned from a general conference at Denver.

Chief operator J. H. Owens has returned from Kansas City after attending a business meeting there.

Assistant all night wire chief R. M. MacDonald, and Miss Frances Murphy, of the Barclay department, were married November 18.

Mr. F. B. Noyes, who has been manager of the Western Union at Hastings, Neb., for the past ten years says of TELEGRAPH AND TELEPHONE AGE: "It's certainly worth the money," and likes it very much.

PHILADELPHIA, POSTAL.

Mr. L. L. Howell, of New York, was a recent caller on business connected with the company.

Mr. T. N. Powers, chief operator, of Chicago, and H. L. Krum, of New York, inventor of the Krum printer, were recent visitors.

Mr. H. D. Moses is a new arrival.

Mr. A. B. Kurtz has gone to Washington, D. C.

It is a valuable privilege to be eligible for membership in a sound and reliable life insurance association which cannot afterwards cancel or alter the terms of the certificate issued. The payment of the sum called for in a benefit certificate blesses alike the recipient and the provider. The Telegraphers' Mutual Benefit Association, 195 Broadway, New York, now the oldest co-operative life insurance association, having been in successful operation for the past 43 years, offers this privilege to all eligible employes of telegraph and telephone service. Write at once for application form and full particulars.

An Interesting Letter.—Mr. A. L. Suesman, of Oak Bluffs, Mass., has facsimiles of an interesting letter from General Thomas T. Eckert to Fred Catlin. A copy may be obtained by sending four cents in stamps to Mr. Suesman.

TRANSMITTING MACHINES

I am placing on the market improved YETMAN TRANSMITTING TYPEWRITERS, and KEY-BOARD TRANSMITTERS without typewriting features. Am prepared to exchange, repair or rebuild all old machines. Write for catalogues and particulars to

James Uncles, NORTH ADAMS Massachusetts

Rubber Telegraph Key Knobs.

No operator who has had to use a hard key knob continuously should fail to possess one of these flexible rubber key caps, which fits snugly over the hard rubber key knob, forming an air cushion. They render the touch smooth and the manipulation of the key much easier. Price, fifteen cents.

J. B. Taltavall, TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

PHILLIPS CODE.

The popularity of Phillips' Code, by Walter P. Phillips, was never more apparent than at the present time. Its acceptance by the telegraphic fraternity, as a standard work of the kind, dates from its first publication, and the constantly increasing demand for this unique and thoroughly tested method of shorthand arranged for telegraphic purposes, has necessitated from time to time the issuance of several editions. The present edition was carefully gone over, a few revisions made, and a number of contractions added, until now this "staunch friend of the telegrapher" is strictly up-to-date in every particular. It has been declared that an essential qualification of a "first-class operator" is a thorough understanding of Phillips' Code.

The use of this system promotes rapid transmission, and for press reports especially was long since declared to be the best ever devised. By common consent it is recognized as standard and everywhere is regarded in the profession as indispensable in contributing to the operator's fund of practical knowledge. In fact not to understand Phillips' Code acts as a distinct embarrassment to the operator.

The price of the book is $1 per copy. Address J. B. Taltavall, TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

ELECTRICAL HOLIDAY NOVELTIES

Electric Lights for the Christmas Tree

NOTHING so delights the children as the lighting of the Christmas Tree on Christmas night.

If it is lighted with little sparkling ELECTRIC LIGHTS, the ecstacy is unbounded, besides all danger of fire is eliminated.

Adapted for use on all 110 volt electric lighting systems. Outfit consists of one or more festoons of silk-covered flexible wire, each festoon with 8 pendant porcelain sockets wired thereon and attaching plug to be screwed into a convenient lamp socket which supplies the necessary current.

A full supply of lamps in assorted colors—Clear, Frosted, Red and Blue—is furnished with each outfit, and one extra lamp is furnished for each festoon.

1 Festoon complete with 8 sockets and 9 lamps.....$2.50
2 Festoons complete with 16 sockets and 18 lamps..... 4.25
3 Festoons complete with 24 sockets and 27 lamps..... 6.00

Dry Battery Lighting Outfits

For Christmas Trees

Outfits are furnished with 8 or 16 lamps, complete with assorted colored lamps, sockets, batteries and battery box, all wired complete with switch ready for use.

We furnish these outfits with from 3 to 12 batteries, so that you may select an outfit in accordance with the length of time it will be required to be lighted up.

The Jove Dry Battery, which we consider superior to any dry cell on the market, is furnished with these outfits.

8-Light Outfits

With 3 Cells of Dry Battery.....$2.75
With 6 Cells of Dry Battery..... 3.50
With 12 Cells of Dry Battery..... 4.50

Add to above prices for Fruit Shaped Lamps, 75 cents; for Flower Shaped Lamps, 80 cents; Lungsten Filament Lamps, 80 cents for each outfit.

16-Light Outfits

With 6 Cells of Dry Battery.....$5.40
With 12 Cells of Dry Battery..... 6.40

Add to above prices for Fruit Shaped Lamps, $1.00; for Flower Shaped Lamps, $1.60; for Mazda Filament Lamps, $1.60 for each outfit.

For Fruit shaped Lamps, add 80 cents for each Festoon to above prices.

For Flower Shaped Lamps, add $1.20 for each Festoon to above prices.

CIRCULARS OR CATALOGUE SENT ON REQUEST.

TELEGRAPHERS OF TO-DAY.

"Telegraphers of To-Day," illustrating the personnel of the telegraphic profession as it existed in 1894, with more than 900 biographical and historical sketches of leading members of the craft, is a unique and valuable publication; it has become standard, being the only work of the kind extant. It contains 354 double-column pages, 7 x 11 inches in size, has gilt edges and is bound in imitation morocco—altogether a handsome volume.

Of this fine publication, becoming more and more valuable as time passes, we have but a few copies left. The original price was $5. In order to readily dispose of these remaining volumes, and place them where they rightfully belong, in the hands of every telegrapher who failed to secure a copy at the higher original price, we have cut the figure to $1 a volume. On receipt of this amount the book will be sent to any address, express charges to be paid by the purchaser. At this low rate, a sum below the cost of binding the book even, no telegrapher who desires to own a copy should fail to obtain one at this time, for this "bargain" price can never be repeated, as the book will soon be out of print. Address J. B. Taltavall, Telegraph and Telephone Age, 253 Broadway, New York.

EDISON BSCO PRIMARY BATTERY

We have some interesting battery information ready to send you—if you will write us concerning your battery requirements. Among the various types, there is a BSCO cell that will render you battery service beyond comparison with any service you have heretofore received. Write for this information to-day.

THOMAS A. EDISON, Inc.

9 Lakeside Avenue, Orange, N. J.

Marshall's Electrical Condensers

FOR TELEGRAPH, TELEPHONE, ELECTRIC LIGHT, X-RAY, EXPERIMENTAL AND WIRELESS SYSTEMS.

Sending Condensers for Wireless made to stand any voltage required. Standard Condensers a specialty. These Condensers are used in all Telegraph offices in America where Standard and ordinary Condensers are required.

CONDENSERS AND ARTIFICIAL LINES for Submarine Cables and Land Lines. Send for Catalogue.

CATALOGUE OF BOOKS ON THE TELEGRAPH.

ABERNETHY, J. P.—The Modern Service of Commercial and Railway Telegraphy, in Theory and Practice, including the Railway Station and Express Service; arranged in Questions and Answers; $2.00.

BATES, DAVID HOMER.—Lincoln in the Telegraph Office; Recollections of the United States Military Telegraph Corps during the Civil War; 432 pages; illustrated; price $2.17.

BELL, JAMES, A.I.E.E.—Submarine Cable Telegraphy; 63 pages, 39 illustrations; $1.00.

BRIGHT, CHAS., F.R.S.E., M. Inst. C.E., M.I.E.E.—Submarine Telegraphs; 800 pages; $25.

BRIGHT, CHAS., F.R.S.E., M. Inst. C.E., M.I.E.E.—Story of the Atlantic Cable; 220 pages; $1.00.

BRIGHT, CHAS., F.R.S.E., M. Inst. C.E., M.I.E.E.—Life Story of Sir Charles Tilston Bright; $5.00.

CROCKER, F. B., AND WHEELER, S. S.—The Management of Electrical Machinery. Fully illustrated; $1.00.

CROTCH, ARTHUR.—Hughes and Baudot Telegraphs; 83 pages, 41 illustrations; $1.00.

DODGE, G. M.—The Telegraph Instructor. This volume, now in its fourth edition, is admirably designed for the student and beginner, for in explanation and illustration it is clear and profuse; 260 pages, $1.00.

DYER, FRANK LEWIS, AND MARTIN, THOMAS COMMERFORD.—Edison: His Life and Inventions. Two Volumes; $4.00 net; sent prepaid for $4.28.

GIBSON, CHARLES R.—How Telegraphs and Telephones Work. A simple explanation in non-technical language of the general principles of electricity as applied to telegraph, telephone and wireless operation; $1.00.

HERBERT, T. E.—Electricity in its Application to Telegraphy. A Practical Handbook Covering the Syllabus of the New Technical Examination. Adopted by the English Post Office Telegraph Department. Fourth edition, with forty-eight illustrations; $3.00.

HOUSTON, E. J.—A Dictionary of Electrical Words, Terms and Phrases; 980 pages; 582 illustrations; $7.00.

HOUSTON, E. J.—A Pocket Dictionary of Electrical Words; cloth, $2.50.

JONES, WILLIS H.—Pocket Edition of Diagrams and Complete Information for Telegraph Engineers and Students. This standard work was (1904) carefully revised and 74 pages and 30 diagrams added, including full descriptions of the newest apparatus lately adopted by the Western Union and Postal telegraph companies. It presents the finest study of the complex subject of the telegraph ever published; it explains clearly the equipment of a modern telegraph office, and is a text-book that no student, operator, engineer or official, no matter what his grade, can afford to be without; 334 pages, 52 chapters, 160 illustrations; $1.50.

LOCKWOOD, T. D.—Electrical Measurement and the Galvanometer and its Uses; 144 pages, fully illustrated with diagrams of connections, engravings of apparatus, etc. $1.50.

LOCKWOOD, T. D.—Electricity, Magnetism and Electric Telegraphy; A Practical Guide and Handbook of General Information for Electrical Students, Operators and Inspectors; 376 pages; 152 illustrations; $2.50.

MARSHALL, PERCIVAL.—Small Accumulators; How Made and Used; an Elementary Handbook for the Use of Amateurs and Students; 50 cents.

MAVER, WM., JR.—American Telegraphy and Encyclopedia of the Telegraph. This fine work, revised and enlarged, treats of the systems, apparatus and operation of telegraphy; 668 pages; 492 illustrations; $5.00.

MAVER, WM. and DAVIS, M. M.—Quadruplex; 128 pages; 63 illustrations; $1.50

MEADOWCROFT, WM. H.—A B C of Electricity. This book begins at the very root of electrical science, and contains a vast amount of useful information; 50 cents.

MEYER, FRED L.—Twentieth Century Manual of Railway and Commercial Telegraphy. This work embraces all kinds of commercial messages, train orders, phrases, etc.; 269 pages; illustrated; $1.00.

MEYER, FRED L.—Railway Station Service. A text-book for those who wish to become properly equipped station, baggage, freight or ticket agents; 216 pages; fully illustrated; $1.25.

MONELL, D. S. H.—The Cure of Writers' Cramp, and the Arm Troubles of Telegraphers. This valuable treatise should be in the possession of every telegrapher suffering from this common annoyance; 50 cents.

OFFICIAL DIAGRAMS of the Postal Telegraph-Cable Company and Repair of Lines. This book has been produced by authority of the Postal Telegraph-Cable Company, and under the personal supervision of John F. Skirrow, associate electrical engineer. All of the engravings are made from the official blue-prints of the Postal company, and are therefore absolutely correct; 134 pages; 105 full-page illustrations; 50 cents.

PHILLIPS, WALTER P.—Phillips Code. A popular, generally used and thoroughly tested method of shorthand arranged for telegraphic purposes, and contemplating the rapid transmission of press reports; also for general newspaper and court reporting; flexible leather cover, pocket size; $1.00.

PRIME, S. IRENAEUS.—Life of S. F. B. Morse. The only work authorized by the family and executors of the great inventor, compiled from original data. This is the finest, most accurate and complete life of Prof. Morse, and includes the history of the invention of the telegraph and the many important business connections with those who were interested with Prof. Morse in the development of the telegraph, that has ever emanated in any shape or at any time from the press; sheepskin; 775 pages, illustrated. The regular price of $6 has been reduced to $3.

POPE, FRANKLIN LEONARD.—Modern Practice of the Electric Telegraph; a Technical Handbook for Electricians, Managers and Operators; 234 pages; 185 illustrations; $1.50.

PREECE, W. H., AND SIVEWRIGHT, J.—Telegraphy. A description of every telegraph system and apparatus used in the English telegraph department; ninth edition; with appendix; 504 pages; 272 illustrations; $2.50.

REID, JAMES D.—The Telegraph in America. A complete detailed history of the telegraph, including the organization of the various telegraph and cable companies; 894 pages; illustrated; full morocco binding. Reduced from $7.00 to $5.00.

SCHNEIDER, N. H.—Electrical Instruments and Testing; with new chapters by Jesse Hargrave, of the Postal Telegraph-Cable Company, on testing wires and cables and locating faults in telegraph and telephone systems; how to use the voltmeter, ammeter, galvanometer, potentiometer, ohmmeter, the Wheatstone bridge, and the standard portable testing sets; 256 pages; 133 illustrations; cloth, $1.00; full limp leather, $2.00.

SCHNEIDER, N. H.—Model Library, comprising 4 books, viz.: Study of Electricity for Beginners; Dry Batteries; Electrical Circuits and Diagrams; Electrical Bells, Alarms, etc.; bound in one volume; cloth, $1.

TALTAVALL, JOHN B.—Telegraphers of To-Day. Biographical and historical sketches of more than 900 leading telegraphers, living and dead; published in 1894; 354 double-column pages, 11 x 14 inches; gilt edges; imitation morocco binding; only work of the kind; of much practical value to those who would keep in touch with the personnel of the profession; reduced from $5.00 to $1.00, express charges collect.

THOM, CHARLES, AND JONES, WILLIS H.—Telegraphic Connections; Embracing Methods in Quadruplex Telegraphy and other Apparatus; 20 plates with circuits distinguished by being printed in three different colors; $1.50.

WATSON, A. E.—Storage Batteries, Their Theory, Construction and Use. An up-to-date work for the practical man; $1.50.

WEBER, W. L.—Handy Electrical Dictionary; 224 pages; 32 illustrations; cloth, 50 cents.

Digitized by Google

WILKINSON, H. D.—Submarine Cable Laying and Repairing; $6.00, revised, 1909.

YOUNG, J. ELTON.—Electrical Testing for Telegraph Engineers; $4.00.

TELEGRAPH SKETCH BOOKS.

LIGHTNING FLASHES AND ELECTRIC DASHES.—A book made up of bright, ably written stories and sketches, telegraphic and electrical, that should find a place in the home of every telegrapher; 160 large double-column pages; profusely illustrated; reduced from $1.50 to $1.00.

PHILLIPS, WALTER P.—Sketches, Old and New, by the author of Phillips' Code, containing a number of telegraph stories, told with all the charm of that delightful storywriter; 200 pages; illustrated; $1.00.

BOOKS ON WIRELESS TELEGRAPHY.

BISHOP, LEON W.—The Wireless Operators' Pocketbook of Information and Diagrams; 200 pages; fully illustrated; cloth, $1.00; leatherette, $1.25; leather, $1.50.

BOTTONE, S. R.—Wireless Telegraphy and Hertzian Waves; diagrams and illustrations; $1.00.

COLLINS, A. FREDERICK.—A History of Wireless Telegraphy, its Theory, Experiments and Results Obtained; 300 pages; 332 illustrations; $3.00.

COLLINS, A. FREDERICK.—Manual of Wireless Telegraphy; 232 pages; 90 illustrations; cloth, $1.50.

EICHHORN, GUSTAV.—Wireless Telegraphy; 126 pages; 79 illustrations; $2.75.

FLEMING, PROF. J. A.—Elementary Manual of Radio-Telegraphy and Radio-Telephony. 340 pages, numerous illustrations; $2.50.

KENNELLY, A. E.—Wireless Telegraphy and Wireless Telephony; illustrated with 84 diagrams and pictures; 1910 edition; $1.00.

LODGE, PROF. OLIVER J.—Signaling Across Space Without Wires. A description of the work of Hertz and his successors. Contains numerous diagrams and half-tone illustrations; $2.00.

MAVER, WM., JR.—Maver's Wireless Telegraphy; Theory and Practice; new edition, 368 pages and 258 illustrations; $3.00.

MORGAN, ALFRED POWELL.—Wireless Telegraph Construction for Amateurs; $1.50.

PIERCE, GEORGE W., A.M., PH. D.—Principles of Wireless Telegraphy, 350 pages, 235 illustrations; $3.00.

ROMSON, LIEUTENANT-COMMANDER S. S.—Manual of Wireless Telegraphy for the Use of Naval Electricians; 129 pages; 60 illustrations; $1.75.

STORY, A. T.—The Story of Wireless Telegraphy; 215 pages; 56 illustrations; $1.00.

TREVERT, EDWARD.—A B C of Wireless Telegraphy; 7 chapters; 20 illustrations; $1.00.

VREELAND, F. K.—Maxwell's Theory and Wireless Telegraphy; 250 pages; illustrated; $2.00.

BOOKS ON THE TELEPHONE.

DOLBEAR, A. E.—The Telephone. An account of the phenomena of electricity, magnetism and sound as involved in its action, with directions for making a speaking telephone; 50 cents.

HOMANS, JAMES E., A.M.—A B C of the Telephone; 350 pages; profusely illustrated; $1.00.

MILLER, KEMPSTER B.—American Telephone Practice, fourth edition; entirely rewritten and greatly extended. This comprehensive study of the subject explains in detail every piece of telephone apparatus; 904 pages; 304 illustrations; $4.00

SMITH, ARTHUR BESSEY, E. E.—Modern American Telephony in All Its Branches; over 800 pages; nearly 600 illustrations. Issued in September, 1911; $2.00.

VAN DEVENTER, H. R.—Telephonology; 586 pages; 700 illustrations; issued 1910; treats of magneto common battery and automatic systems, composite telegraphy and telephony and describes all kinds of modern apparatus; $4.00

CABLE CODES.

A B C CODE, fourth edition; $5.00.

A B C CODE, fifth edition. This book is entirely different from the work known as the "A B C Code, Fourth Edition," and the two should not be confounded; $7.00.

A 1 UNIVERSAL COMMERCIAL ELECTRIC TELEGRAPHIC CODE; $7.50.

LIEBER, B. FRANKLIN.—Telegraphic Cipher Code; $12.00.

MCNEILL, BEDFORD.—Code; $6.00.

MORRING, C. A., AND NEAL T.—Telegraphic Mining Code; $5.00.

OFFICIAL VOCABULARY, compiled by the International Telegraph Bureau at Berne, containing over 1,000,000 carefully selected words; four volumes, $30.00.

POSTAL TELEGRAPH CABLE CODE; $3.50.

WESTERN UNION TELEGRAPHIC CODE.—Contains 175,000 words and phrases, carefully selected from the official vocabulary; $16.00; with flexible leather cover, $18.00; Pocket edition, unabridged, $10.00.

INTERNATIONAL CABLE DIRECTORY OF THE WORLD.—Contains the names, lines of business and cable addresses of upwards of 30,000 subscribers to the Western Union Telegraphic Code; a three-year's subscription, $16.00.

Any other code can be furnished on order.

Express or carrying charges on Cable Code Books are not prepaid; these books are sent charges collect.

Any electrical book published, American or foreign, will be sent promptly to any address in the world on receipt of price, postage or express charges prepaid.

Address, and make post office money-orders, express orders, drafts and checks, etc., payable to J. B. Taltavall, Telegraph and Telephone Age, 253 Broadway, New York.

TELEGRAPH AND TELEPHONE AGE

ESTABLISHED 1883.

A Semi-Monthly Journal devoted to land-line Telegraphs, Telephones, Submarine Cable interests, Radio-Telegraphy and allied industries.

Endorsed by every telegraph official in the railroad and commercial field. Contains interesting personals, educational articles from the pens of the most expert men in the service, scientific and technical articles descriptive of the latest inventions, reminiscence by the leading telegraph writers and much other matter of absorbing interest to everyone identified with the telegraph.

Terms of Subscription: For one year, United States, Philippine Islands, Cuba, Mexico, $2. Canada, $2.50. All other Foreign Countries, $3.

Headquarters for all Telegraph, Telephone, Wireless and Electrical Books and Cable Codes. Orders invariably filled the same day they are received.
