Design Data for *m*-Derived Type Filters

PART II

By the Engineering Department, Aerovox Corporation

INDUCTANCE and capacitance values given in the tables appearing in this issue are for low- and high-pass series- and shunt-derived filters of 500 ohms and 10,000 ohms characteristic impedance. Constants for band-pass and band-suppression sections will be given in the next issue.

The inductance and capacitance values for each type appear directly opposite the corresponding cut-off frequencies which are listed in the first column. No calculations are necessary if the tables are employed directly, except when single sections are to be combined for sharper cut-off, as will be explained in a succeeding issue.

Except where otherwise noted in the tables, frequencies are stated in cycles per second, inductances in henries, and capacitances in microfarads. If it is necessary to employ a characteristic impedance (*R*) other than the values for which components are listed, the designer must first locate in the table components for a 500-ohm filter. The inductance value for the new impedance will then be obtained by multiplying the listed *L* value by *R*/500, and the capacitance value for

the new impedance by dividing the listed *C* value by *R*/500.

PRECAUTIONS IN FILTER DESIGN

Components selected for use in *m*-derived filter sections must be of good quality to insure efficient operation. The d.c. resistance of all coils, for example, must be low and the *Q* of all coils and capacitors as high as practicable for the operating frequency, for best results. Excellence of filter action will depend upon the efficiency of the parts employed and the accuracy of their values.

Coils for use at commercial power frequencies and low audio frequencies may be of good iron-core construction, while those intended for filters which will operate at the higher audio frequencies should have powdered-iron cores. Filter coils for use at radio frequencies should be universal-wound, preferably with Litz wire, in order to minimize distributed capacitance and when the operating frequency permits, should be provided with powdered-iron cores and rings for improvement of *Q*. Appropriate shielding of individual components

from each other and shielding of the entire filter unit is good practice.

In filter sections where capacitance is shown connected in parallel with inductance, the distributed capacitance of the coil may be figured into the total shunting capacitance given by the *C* values in the tables. In all other cases, every expedient must be taken to keep the distributed capacitance of inductive arms low in order to prevent undesired shunting effects.

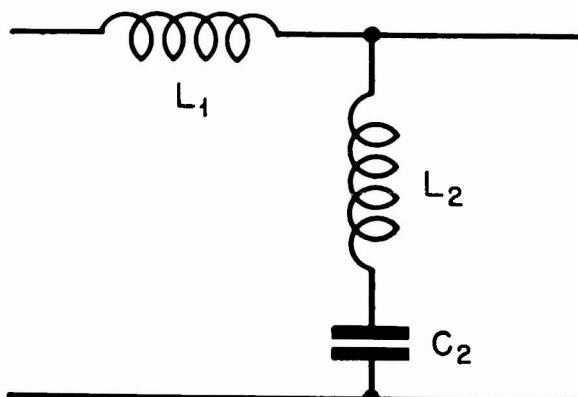

Inductance and capacitance of *m*-derived filter elements must be accurately maintained. The capacitor arms, more so than the coil arms, lend themselves to close final adjustment by means of paralleled units. In radio-frequency units, where capacitances required are generally small enough to permit the use of variable or partially-variable units, at least a portion of the total capacitance of any arm might be a trimmer condenser for accurate final setting of the arm. Likewise, at certain frequencies it is possible to obtain inductive trimming in a coil arm by varying the length of powdered-iron core enclosed within the field of the coil.

AEROVOX PRODUCTS ARE BUILT BETTER

High Altitude

OIL-FILLED CAPACITORS

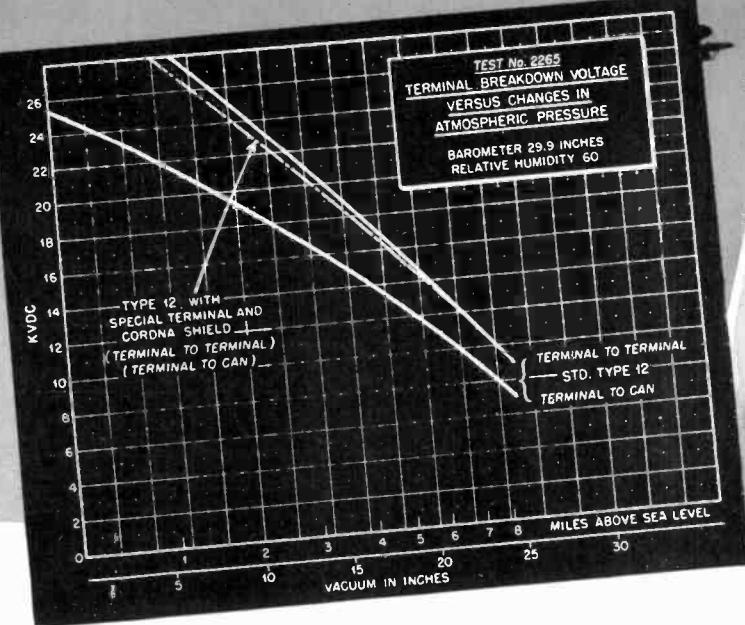

Photo Courtesy of
Bell Aircraft
Corp., makers of
the famous Air-
acobras.

- Type 12 is a standard Aerovox capacitor. Exclusive Hyvol dielectric oil. Special ceramic insulators on ribbed cap, for ratings up to 7500 v. D.C.W.

At high altitudes encountered in aircraft applications, however, things do happen. While Hyvol maintains the effective capacitance even at sub-zero temperatures found high above the earth, the terminal breakdown voltage drops rapidly in the rarefied atmospheres.

To meet such conditions, Aerovox engineers redesigned the terminals of Type 12. One terminal became

a short screw post. The other, a tall ceramic insulator with corona shield at top. Result: minimized surface leakage; minimized corona losses; greatly stepped-up breakdown voltage at high altitudes. The chart tells the story.

Ingenious revisions and adaptations of standard Aerovox types, such as this, are meeting unusual requirements — quickly, fully, economically.

Write for latest Transmitting Capacitor Catalog. And try A.A.E.* on that tough capacitance problem.
