Library of Congress Catalog Card Number: 78-51612

Printed in the United States of America.

Preface

Every owner of a shortwave receiving set is familiar with the thrill that comes from hearing a distant station broadcasting from a foreign country. To hundreds of thousands of people the world over, shortwave listening (often referred to as swl) represents the most satisfying, the most worthwhile of all hobbies.

It has been estimated that more than 25 million shortwave receivers are in the hands of the American public, with the number increasing daily. To explore the international shortwave broadcasting bands in a knowledgeable manner, the shortwave listener must have available a list of shortwave stations, their frequencies, and their times of transmission. To keep abreast of the ever-increasing public interest in music, news, and the exchange of cultural ideas from foreign lands, the seventh edition of this book has been completely revised to include the most recent changes in broadcasting schedules. A new format has been adopted in order to present the shortwave schedules and frequency information in a more comprehensive style and in a manner that can be utilized by shortwave enthusiasts the world over. The listings presented in this edition are arranged conveniently in five sections as follows:

Section 1 contains a brief explanation of shortwave propagation in easy-to-understand language, along with forecast tables that the swl'er can use as a guide to the best wavelength bands to be used for listening to stations in various geographic locations. These tables cover from early 1978 through February 1980. Section 1 also contains a do-it-yourself method that will enable the nontechnical swl enthusiast to predict daily ionospheric conditions with a high degree of accuracy.

Section 2 consists of worldwide shortwave broadcasting stations listed alphabetically according to country and city within the country. Important particulars such as geographic location, rf carrier output

in kilowatts (kW), interval signal (Int), announcement (Ann), frequency in kilohertz (kHz), and hours of transmission in Coordinated Universal Time (UTC) for each station are given.

Section 3 contains a listing of shortwave broadcasting stations, including the country and city, in numerical order by frequency.

Section 4 contains a listing of shortwave news broadcasts that are transmitted in English and other principal languages. The tabulation is arranged by UTC and alphabetically by country.

Section 5 includes the official names and business addresses of the shortwave stations so that the shortwave listener can send verification reports of transmissions heard. QSL-ing, as it is called, is explained in this section.

The tabulations in this book by no means represent all of the shortwave broadcasting stations in the world. Only those transmitting in English and a few of the other major languages of the world are included. Every effort has been expended to make this edition as useful and up to date as possible. However, the accuracy cannot be guaranteed; carrier frequencies and program scheduling may change without notice. All swl'ers are cordially invited to comment on any additions, deletions, or changes that may be noted, so that these can be incorporated in future editions.

Introduction

To pursue the very interesting and stimulating hobby of shortwave listening in an informed manner, the hobbyist must be aware of a few salient facts. These important items are discussed in the following paragraphs. Every effort has been made to simplify the data. If detailed information on a particular subject is desired, it is suggested that a textbook be consulted.

FREQUENCY

All transmission frequencies in this book are expressed in kilohertz (kHz). Receiver dials are often calibrated in megahertz (MHz). To convert kilohertz to megahertz, simply divide by 1000; conversely, to convert megahertz to kilohertz, multiply by 1000. For example, 9100 kHz is 9.1 MHz, and 5 MHz is 5000 kHz. The tuning dials of most shortwave receivers omit fractional numbers. For example, the numerals 9, 10, 15, 20, etc., appearing on the tuning dial stand for 9 MHz, 10 MHz, 15 MHz, and 20 MHz. To determine the location of a station broadcasting on 9.100 megahertz, the operator needs only to mentally divide the space between 9 MHz and 10 MHz, and position the receiver tuning-dial marker one-tenth of that spacing beyond 9 MHz. Some receivers have precision dial calibrations that are expressed directly in kilohertz.

Some receivers may use the terms kilocycles (kc) or megacycles (mc) instead of kilohertz and megahertz. The terms have the same significance; that is, "kilocycles" is the same as "kilohertz" and "megacycles" is the same as "megahertz." Formerly, the term "cycles per second" was used to designate frequencies. The terms kilocycles and megacycles (actually kilocycles per second and megacycles per second) were used to designate 1000 and 1,000,000 cycles per second. The newer term, hertz, was adopted partially because

of the fact that the "per second" portion of the previous designation was often omitted (though without the time element the term is meaningless) and partially to honor Heinrich Hertz, considered by many as the father of radio. The term hertz (Hz) means cycles per second; thus, the time is included as part of the term. Likewise, kilohertz means 1000 cycles per second (1000 Hz) and megahertz means 1,000,000 cycles per second (1,000,000 Hz or 1000 kHz).

By international regulations, entered into by most countries, certain groups, or "bands," of radio frequencies have been set aside in the high-frequency radio spectrum for international shortwave broadcasting (Table 1). Most of the world's shortwave broadcasting stations operate within these bands; some, however, operate outside the band limits, usually adjacent to a particular band within 100 or 200 kHz. Occasionally you might hear that a particular station is operating in the "16-meter band," or the "41-meter band," etc. Table 1 lists these designations for the various bands.

Table 1. International Shortwave Broadcasting Bands

Frequency (kHz)	Band (Meters)
2300-2495	120
3200-3400	90
3900-4000	75
4750-5060	60
5950-6200	49
7100-7300	41
9500-9775	31
11,700-11,975	25
15,100-15,450	19
17,700-17,900	16
21,450-21,750	13
25,600-26,100	11

CALL LETTERS

Any listener to conventional radio and television is aware of the call letters assigned to transmitting stations, for example, KFI, Los Angeles; KOA, Denver; WLS, Chicago; WNBC, New York; etc. Some countries have assigned call letters to their high-frequency stations; however, the call letters are rarely used for station identification. Usually the announcer of a shortwave station will merely say, "This is Radio Japan," "This is RSA, Radio South Africa," or "This is the Voice of America."

POWER

The transmitting power listed in Section 2 of this book is expressed in kilowatts (kW). Most international shortwave stations use transmitting equipment with a power of 50 kW or more to ride through the

interference and atmospheric noise. This high power does not mean that stations of 5 kW or less cannot be heard. Quite the contrary—amateur shortwave operators have repeatedly disproved this by conversing with fellow "hams" all over the world using considerably less than 1 kW of power. The unpredictability of shortwave listening is what makes the hobby interesting and the end result more rewarding.

PROGRAM TARGET AREAS

Most international shortwave broadcasting stations employ directional antenna arrays to beam radio transmissions to a specific geographical area, such as Europe, North America, Africa, Asia, etc. These programmed areas are indicated in the Section 2 station listings.

In most instances, due to overlap of target areas and because of the nature of shortwave radio wave propagation, you may hear broadcasts that are not specifically beamed to your area. For example, BBC transmissions directed to Africa can often be received in Southeast Asia. However, for best reception and maximum signal strength, choose a transmission that is beamed to your geographical location. Those transmissions not indicated as beamed to a specific area can be assumed to be omnidirectional.

All broadcasts listed in *Shortwave Listener's Guide* are daily transmissions unless otherwise noted.

MULTIPLE-FREQUENCY TRANSMISSIONS

To compensate for adverse ionospheric conditions, interference from other radio stations, jamming, and technical malfunctions, stations may use several frequencies beamed to the same general geographical area. When radio interference or low received signal strength is encountered, the listener should try a different listed frequency or tune to the station at another time.

TIME ZONES AND LOCAL TIME

The United States is divided into seven standard time zones, designated as Eastern, Central, Mountain, Pacific, Yukon, Alaska/Hawaii, and Bering. The Canadian provinces are in the first five of these seven zones, plus the Atlantic time zone on the east. In addition, Newfoundland and Labrador advance the clock one-half hour ahead of Atlantic time. The various time zones are shown in Fig. 1. Each time zone is approximately 15 degrees of longitude in width, and all places within a given zone use the time reckoned from the transit of the sun across the standard time meridian of that zone. The time for each zone, starting with the Atlantic time zone and moving westward, is basically reckoned from the 60th, 75th, 90th, 105th, 120th, 135th, 150th, and 160th meridians west of Greenwich, England (prime meridian). The actual division lines separating the various time zones

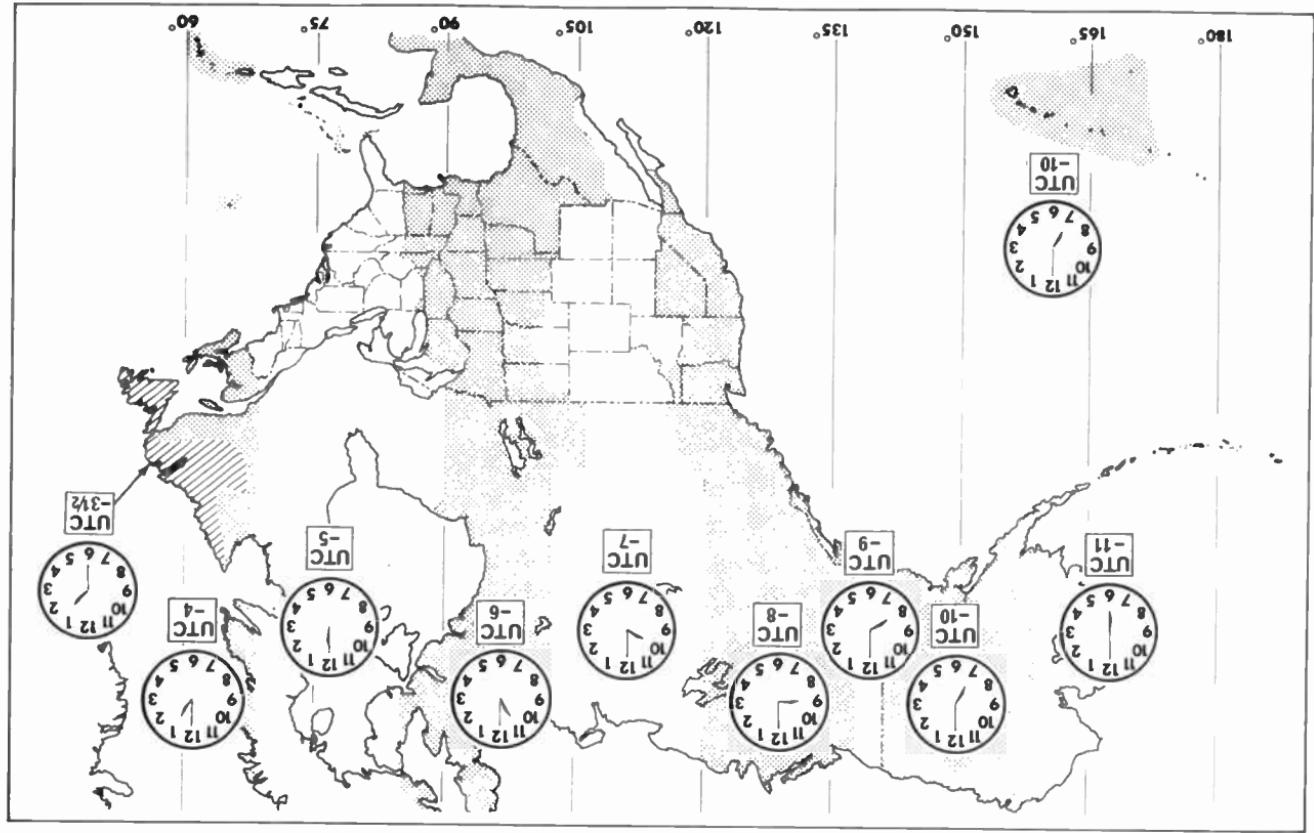

Fig. 1. North American time zones.

wander somewhat to conform with local geographic areas and local convenience.

The times of all events listed in *Shortwave Listener's Guide* are given in Coordinated Universal Time (UTC), which is coordinated through international agreements by the International Time Bureau (BIH, which stands for *Bureau International d l'Heure*, located in Paris, France) so that time signals broadcast from standard frequency and time stations throughout the world (such as WWV in Fort Collins, Colorado) will be in close agreement. The specific hour and minute listed is actually the time in the reference time zone centered around Greenwich, England, and is generally equivalent to the more familiar "Greenwich Mean Time" (GMT). To obtain the local time of the event, it is necessary to add or subtract a given number of hours from the UTC. For example, to obtain the local time in the Eastern time zone, five hours must be subtracted from the time shown; for the Pacific time zone, eight hours must be subtracted.

The standard time differences for principal cities of the United States and Canada are indicated in Table 2. Standard time differences for cities throughout the rest of the world are indicated in Table 3.

* At 1700 hours UTC, the standard time in US and Canadian cities is as listed.

By Federal law, daylight saving time (DST) is observed in the United States from 2:00 a.m. on the last Sunday in April to 2:00 a.m. on the last Sunday in October. (A few states have elected to exempt themselves from the observance of daylight saving time.) Daylight saving time is achieved by advancing the clocks one hour. For example, an event listed for 9:00 p.m. EST would take place at 10:00 p.m. EDT.

* At 1700 hours UTC, the standard time in world cities is as listed.

† Next day.

Notice that in this book times are given in the 24-hour system. In this system, time is expressed by a four-digit number in which the first two digits indicate the hour and the last two digits indicate the minute. The hours are numbered starting with midnight as zero. For example, 12:30 a.m. is 0030, 10:30 a.m. is 1030, 1:00 p.m. is 1300, 6:25 p.m. is 1825, etc. Usually, midnight is written 0000, but occasionally it may appear as 2400.

Ionospheric Propagation and Predictions

Two types of radio-frequency waves are emitted from a shortwave transmitting antenna—the ground wave and the sky wave. The ground wave is of no significance for shortwave reception. The sky wave, however, upon leaving the transmitting antenna travels upward at various angles above the surface of the earth. It would simply continue out into space were it not bent sufficiently to bring it back to the earth. The medium that causes such bending is the ionosphere, a region in the upper atmosphere where free ions and electrons exist in sufficient quantity to cause a change in the refractive index. Ultra-violet radiation from the sun is considered to be responsible for the ionization. For a given intensity of ionization, the amount of refraction becomes less as the frequency of the wave becomes higher. The bending is smaller, therefore, at high frequencies than it is at low frequencies. If the frequency is raised to a high enough value, the bending eventually will become too slight to bring the wave back to earth. At frequencies beyond this point, long-distance shortwave communication becomes impossible.

Because an increase in ionization causes an increase in the maximum frequency of waves that can be bent sufficiently for long-distance communication, it can be seen that slight variations in sun radiation caused by sunspots, solar flares, and other solar disturbances can affect shortwave signal reception.

The amount of ultraviolet radiation reaching the earth varies considerably during a 24-hour period due to the rotation of the earth and because of sunspots and solar flares. Furthermore, the average sunspot number varies over an approximate 11-year cycle. At the time of maximum sunspots, station reception on the 11-meter band

is possible over great distances. However, at the time of low sunspot number the 11- and 13-meter bands are virtually useless. Solar activity reached a maximum in 1969 and then declined until it reached its present low in the latter part of 1974. It is expected to remain at this low ebb until 1978, at which time it is predicted to rise slowly.

At times, ionospheric conditions may cause a temporary "signal blackout" from some areas of the earth. Therefore, even though a station might be listed as being "on the air" for a particular time period, ionospheric conditions may prevent the signal from being heard.

During the past several years, communications engineers and scientists have conducted a concentrated worldwide effort to learn more about the mysteries of the ionosphere, its makeup, and its effect on radio transmission and reception. Many satellites and space laboratories have been launched and more than 100 ground stations have been established to study the phenomenon. The results of this continuing study have produced a much greater understanding of electromagnetic wave propagation, and the mass of data compiled by these satellites and ground stations is constantly being fed into computers and data processing machines and used for predicting future propagation conditions. Tables 1-1 through 1-8 have been compiled from such computer programs, and are based on the latest propagation data available. The tables are simple to use. First, locate the chart containing the current month. Second, find your geographic location in the left-hand column titled "Listener's Area," and in the appropriate Coordinated Universal Time (UTC) horizontal line, move to the right to the desired "Broadcasting Station Location" vertical column. Use the following legend to identify your listening area and the areas of the world in which the broadcasting stations are located:

Legend:

- I—North America (East)
- II—North America (West)
- III—Central and South America
- IV—Europe and North Africa
- V—Central and South Africa
- VI—Middle East and South Asia
- VII—East Asia and Far East
- VIII—Australia and New Zealand

The tables show the wavelength band (in meters) that should provide optimum reception in the listener's area for the month and time listed. In some instances, because of slight daily variations in ionospheric density, it may be possible to receive broadcasting stations in the next higher or next lower wavelength bands; however, best reception can be expected on the bands listed.

These tables show the *predicted* wavelength bands that will provide the listener with optimum reception. However, these are long-range predictions and can be subjected to daily fluctuations. The following paragraphs will describe a daily, do-it-yourself method that

Table 1-1. Favorable Shortwave Broadcast Bands (March–April 1978)

* See legend on page 16.

the average nontechnical shortwave listener can use, and, with a little practice, will be able to perform short-term ionospheric predictions with a high degree of accuracy.

As stated earlier, the ionosphere is formed by ultraviolet radiation from the sun. The stronger the radiation, the more dense the ionosphere will be; the weaker the radiation, the less dense the ionosphere will be. Thus the stronger the radiation layer, the better will be the shortwave propagation. Solar flux is a measure of the level of solar radiation and is thus an indication of the general state of the ionosphere. The use of solar flux as a measure of daily solar activity is now preferred rather than the daily sunspot count because solar flux has been found to be more direct and objective. It is also much more sensitive to change than the sunspot count. During the present low solar activity, daily solar flux levels will generally range between 70 and 100. The solar flux level is monitored at numerous observatories throughout the world.

While ultraviolet solar radiation produces the ionosphere, another type of solar radiation, called *solar particle radiation*, tends to weaken or deteriorate the ionosphere, or in some instances make it disappear completely. Because solar particle radiation also affects the earth's magnetic field, its level can be determined with the use of certain electronic instruments.

The earth's magnetic field is also monitored by several observatories throughout the world, and is reported as a worldwide planetary A index (A_p), which is the daily average measured by all stations. Since one full day is required to determine the A_p , it is not a real-time index.

Recently, the National Bureau of Standards radio station WWV began broadcasting both the A_p index (for the previous day) and a real-time three-hourly K index at eighteen minutes past each hour. The K and A indices are related approximately as follows:

$K = 0$	1	2	3	4	5	6	7	8	9
$A_p = 0$	4	7	15	27	48	80	140	240	400

The K index varies over a scale of 0 to 9. The higher the K value, the greater is the influx of solar particles, which in turn causes weaker signals and increased noise and fading conditions. Solar flux indicates the degree of ionization in the earth's atmosphere, and the A or K index measures the activity of the earth's magnetic field. Both taken together give a relatively accurate picture of overall ionospheric propagation conditions.

Fig. 1-1 can be used to determine the high-frequency ionospheric propagation conditions. For example, if the solar flux level is 80 and the geomagnetic index K is 2 (or an A_p index of 7), one can expect high "high normal" conditions.

With few exceptions, the *higher* the value of solar flux and the *lower* the value of magnetic activity, the better will be the ionospheric propagation. Conversely, the *lower* the solar flux and the *higher* the magnetic activity, the poorer will be the receiving conditions.

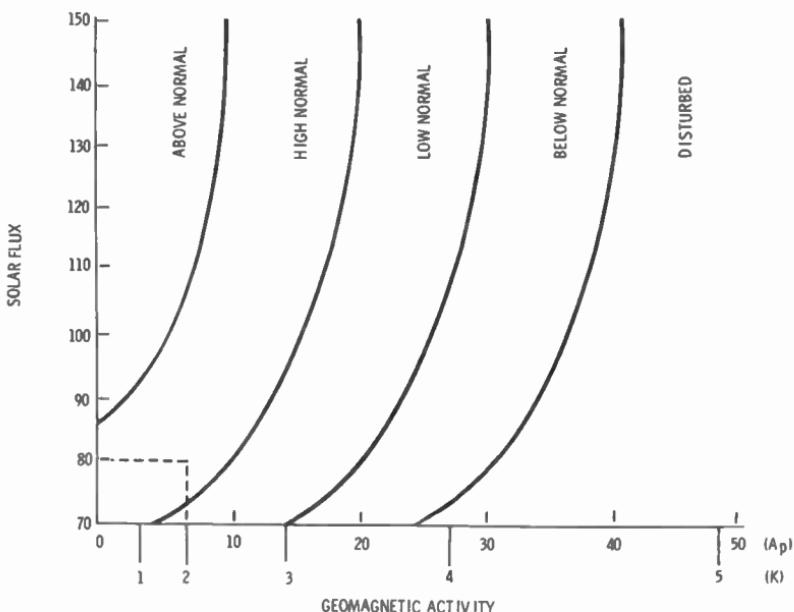

Fig. 1-1. Solar flux index versus geomagnetic activity.

A typical WWV radio broadcast is as follows: "Solar terrestrial indices for 11 June follow: solar flux index 85; A index 4. Repeat; solar flux index 85; A index 4. The K index at 1800 UTC 12 June was 1. Solar terrestrial conditions for the last 24 hours follow: solar activity was very low; the geomagnetic field was quiet. The forecast for the next 24 hours follows: solar activity will be low; the geomagnetic field will be unsettled."

The preceding typical WWV broadcast can be translated as follows: Since the broadcast was received on 12 June UTC, the solar flux reading of 85 and a A_p index of 4 was for the *previous* day. The current or real-time observation of the K index was taken at Boulder, Colorado on the current date at 1800 hours UTC. Using Fig. 1-1, both the previous day's reading and the present observation indicate a "high normal" condition, or good radio reception. However, a slight deterioration can be expected in the immediate future.

If the shortwave radio enthusiast maintains a daily log of WWV broadcasts and simultaneously makes observations of receiving conditions in his location, he will soon be able to make short-term ionospheric predictions with a high degree of accuracy. These observations are not only of great use to the swl'er, but can add to the enjoyment of his chosen hobby as well.

Due to the many variables involved and solar uncertainties, it is extremely difficult to predict shortwave propagation conditions beyond 18 months. For example, the next sunspot cycle is already one

year late in starting. Since solar activity is responsible for the ionospheric changes, the reader can appreciate the complexities involved. Therefore, it is suggested that if the solar activity has increased appreciably during the early months of 1979 as indicated by the broadcasts from radio station WWV, all predicted wavelength bands in Tables 1-1 through 1-8 should be advanced by a factor of one; i.e., if the predicted band to use for best reception between areas for a specific time is the 31-meter band, the reader should also check the 25-meter band—reception might be better.

Stations by Country and City

AFGHANISTAN

Kabul (35°00'N, 69°00'E)

Ann: "Da Radio Afghanistan Kabul Dai."
Int: A folk song played on a flute.

Stations:

International Shortwave News Broadcasts

International shortwave radio broadcasting provides a means by which the people of other nations may learn the history, culture, and folklore of the originating country. But more important, it is a dynamic medium by which national and international news and commentaries can be broadcast to the ears of millions of listeners outside the borders of a country.

The purpose of this section is to provide the enthusiast with a convenient listing of all English-language news broadcasts transmitted from the capitals of the world. When, in some instances, a specific country does not broadcast in English, the country and the language used for the news broadcast are listed in Section 2.

To use this section, note the time a specific country broadcasts the news, then refer to Section 2 for further details of the transmission. All time indications are in UTC.

Verification Reports [QSL-ing]

Most international shortwave broadcasting stations are interested in knowing how well their transmissions are being received by listeners in other countries, particularly in those areas to which the signals are beamed. Listener reports are useful to the station engineering staff in selecting frequencies to avoid interference or atmospheric disturbances. They are also useful to the program manager in determining listener reactions to the program. In return for these reception reports, a station will usually mail to the sender a verification card (QSL card).

To make your report as brief but as useful as possible, the following items must be included (preferably typewritten).

1. Date and time (UTC) the transmission was heard and the length of time you listened, such as "0700-0800 hours UTC, July 10, 1978."
2. Reception report using SINPO code (Chart 1, page 131).
3. Make, type, and model of receiver used.
4. Type of antenna used (height, length, whether it is erected in the clear, etc.).
5. A brief description of what the program contained, such as the musical selections played, subject material of the commentary, or any other program data. The station staff uses this information to identify the program as positively being theirs and to verify that you did, indeed, hear it.
6. Comments regarding reception (unusual interference, fading characteristics, modulation quality, and any other transmission irregularities).

7. Program comments and suggestions.
8. Your name and complete mailing address.

Allow seven to ten weeks for receipt of your QSL card. It is advisable to send your report via air mail. Consult your local postal authorities for postal rates. Mail your report to the address given in the following list.

AFGHANISTAN

Radio Afghanistan
