Parallel-Operated Components Raise Computer Speed . . . 34

are preferred for potting, sealing and encapsulating!

Epon resins are the number 1 choice for potting, laminating, sealing and encapsulating, because they provide an almost perfect combination of electrical and physical properties.

**Potting and Encapsulating.** Epon resins possess outstanding adhesive qualities . . . form strong bonds to metal and glass. They assure an air-

2

tight enclosure for delicate components and vacuum tubes. Even when exposed to solder bath temperatures, Epon resin retains its dimensional stability.

**Sealing.** Epon resin-based insulating varnishes and potting compounds provide excellent moisture sealing. They offer outstanding resistance to

solvents and chemicals even at elevated temperatures.

Epon resins also produce base laminates of superior dielectric properties when laid up with inert fibrous fillers. These laminates can be sheared, punched, drilled, and bath-soldered.

For complete information on Shell's family of Epon resins, write us now.

#### HIGHLIGHTS OF ISSUE

#### 

By operating its components in parallel the "Trice" digital computer achieves speeds comparable to analog computers. Self-contained digital integrators, multipliers, and servos are interconnected by means of a plugboard which serves as the means of programming. 100,000 iterations per second in parallel is obtained by this method of construction. Word length is 30 bits.

#### 

The bandwidth of an i-f amplifier can be changed just by varying the bias of a single tube. The change can be as high as 20 to 1 in a 30 mc i-f strip.

#### Design Curves for Thermistor Transistor Stabilization . . 26

One of our most popular contributors, Mr. Nisbet again provides the designer with some invaluable short cuts. He supplies an array of curves which make the selection of thermistors for transistor stabilization a rapid and simple operation. Some specific examples make the presentation particularly lucid.

#### Variable Speed Tape Drive . 40

This tape mechanism can search through a reel of tape faster than most computers can digest information. And, it works without a capstan. September 17, 1958 Vol. 6 Number

#### SUBSCRIPTION POLICY

ELECTRONIC DESIGN is circulated only to qualified electronic design engineers of U. S. manufacturing companies, industrial consultants, and government agencies. If design for manufacturing is your responsibility, you qualify for subscription without charge provided you send us the following information on your company's letterhead: Your name and engineering title, your company's main products, and description of your design duties. The letter must be signed by you personally.

ANY ADDRESS CHANGES FOR OLD SUBSCRIBERS NECES-

SITATES A RESTATEMENT OF THESE QUALIFICATIONS. Subscription rate for non qualified subscribers-\$15.00 for 1 year only.

## BEHIND THE NEWS

With this issue, we are beginning a more comprehensive news department for the design engineer. Each major development will be probed for significance, implication and application. We're out to get the design news "behind the news." Our new format will permit a more cohesive and attractive presentation.

# Computer Simulation Speeds TV, Speech Research

Use of general purpose digital computers in the simulation of new coding and transmission devices shows promise of accelerating and broadening speech and television research, according to scientists at Bell Telephone Laboratories. The simulation techniques also promise to reduce greatly expense and time lags, and thus make it easy to investigate a large number of approaches to coding and transmission problems.

In speech research, speech is sampled; each sample is quantized into 10 bits or 1024 amplitude levels and delivered to a magnetic tape recorder. These coded samples are recorded in seven parallel tracks, with 200 characters to the inch of tape. These tapes are then fed into the computer, where they are processed according to pre-assigned programs based on the coding or transmission scheme being investigated. The processed signals are then re-recorded, decoded, and played back for analysis and listener evaluation.

Computer memory requirements for speech processing are severe due to the large amount of data generated by even a short section of speech. Rapid access memory units must have a capacity of several seconds of speech to be useful. A speech transmission scheme known as the "Extremal" method, studied by simulation at Bell Labs, illustrates the advantages of the new technique. In its simplest form, only the extremes, or peaks and valleys, of a speech wave are sampled. The amplitudes and time of occurrence of these points are then transmitted, instead of a detailed representation of the entire wave. At the receiver, an approximation of the speech wave is generated by interpolating a suitable mathematical function between these points.

Listener evaluation of the simulated speech produced in initial tests showed that intelligibility is high—above 90 per cent sentence intelligibility—but that the

#### BEHIND THE NEWS

quality is somewhat below that of commercial telephones.

Reports so far indicate that a total of five minutes of speech was synthesized. Including "de-bugging," about three hours of computer time was expended at a cost of \$1500. About four man-months of time was spent, partly in programming, but mostly in determining what to investigate. These figures are substantially less than required to build an actual laboratory model to perform the same function, roughly 1-1/2 man-years and \$50,000 in equipment costs. Digital simulation has been applied to a number of other speech problems.

Picture coding research has also been carried on by computer simulation. In order to hold machine time and memory requirements to a reasonable level, the system uses an input picture of 100 x 100 elements, corresponding to an area about 1/25 that of a conventional TV frame. This 10,000 element "window" has proven to be of sufficient size to allow critical evaluation of the processed images. For typical coding schemes, the total computer time required is 5 to 10 seconds per picture.

A magnetic tape recording of the video signal is prepared by scanning a square picture with 100 scanning lines in 2.4 seconds. Each picture dot is quantized to 10-bit accuracy, providing 1024 amplitude levels, and recorded in the same form as the speech samples described above. The resulting signal is rooted, mixed with a synchronizing waveform in the conventional manner, and band limited to 2500 cps.

In playback, the computed picture signal is converted back to analog form. It is then passed through a low-pass filter, and displayed on a monitor with two kinescope tubes. One of these tubes has a show phosphor for direct viewing, while the other has a fast phosphor for photography.

Regional Sales Offices: 9501 W. Grand Avenue, Franklin Park, Illinois. 5236 Santa Monica Blvd., Los Angeles 29, California Raytheon makes: Magnetrons and Klystrons, Backward Wave Oscillators, Traveling Wave Tubes, Storage Tubes, Power Tubes, Miniature and Sub-Miniature Tubes, Semiconductor Products, Ceramics and Ceramic Assemblies

A coding scheme which may have widespread significance in TV transmission, known as "Predictive Quantizing," has been studied by both simulation and conventional methods. This scheme takes advantage of the relatively low level of viewer perception during periods of scene change or motion, and in areas of picture confusion, these being the only regions in which predictive coding systems make significant errors. The method involves quantizing the difference between the original continuous signal and a predicted version of that signal. It employs fine quantum steps for small errors, and coarse steps for large errors, where the predictor and the viewer are surprised. This tapering of steps in the quantizing staircase allows the use of a smaller number of total levels, and thus reduces the channel capacity requirements.

A limiting case of predictive quantizing, in which the predictor is simply a one-sample delay, has been tested both with the simulation equipment described and with standard 525-line television, and found to afford a picture not significantly degrated from the original, and requiring only three bits per picture dot.

#### Ice Glow By Cerenkov

Under the impact of two million v electrons from a high-voltage Van de Graaff accelerator, a 50 lb block of ice gives off a visible glow known as Cerenkov radiation. The radiation detector developed by Westinghouse, Pittsburgh, Pa., uses an "electric eye" to detect the same glow in ordinary water from which the intensity of the atomic radiation causing the glow is measured. For protection, the photograph was taken through a circular three-foot-thick window containing a transparent solution of zinc bromide. The window is embedded in the equally thick concrete walls surrounding the Van de Graff machine.

# LEACH ELECTRONIC RELAYS SOLVE THESE PROBLEMS:

#### malfunction due to vibration and shock

Exclusive counterbalanced armature with rigid central pivot eliminates armature flutter, insures overtravel and high contact pressure.

#### □ internal contamination

Inorganic, contaminant-free ceramic actuator prevents formation of gases. Drawn aluminum can is crimped to header to prevent introduction of flux. Entire unit hermetically sealed and mass spectrometer checked.

#### malfunction at elevated ambients

Magnet coil wound with Teflon insulated magnet wire on one-piece Kel F bobbin.

#### BALANCED ARMATURE RELAY

Type 9229 2 PDT 5 amp, 3 amp, microamp

#### **FEATURES**

Rectangular configuration Stud or bracket mountings Terminals—solder lug or potted leads

Silver alloy or gold alloy contact material Solid or bifurcated contacts Coils available for ac or dc

#### TYPICAL RATINGS

Contact ratings (resistive) @ 28 vdc
or 115 vac single phase
3 amp @ 125°C ac and dc
5 amp @ 85°C (dc only)
Minimum operating cycles—100,000
Weight—approx.—0.125 lbs.
Shock—50 G's
Vibration—15 G's to 2,000 cps
Temperature range—70°C to +125°C

Applicable specifications—MIL-R-6106C Class A5, A8, B8, minimum current tests applicable; MIL-R-5757B Class A and B Also available for special requirements such as microamp switching, high vibration and special mountings.

**LEACH'S COMPLETE LINE** of *Balanced-Armature* electronic, missile and aircraft relays is described in our new catalog. Write today.

#### BEHIND THE NEWS

#### Fast Wave Parametric

Fast wave parametric amplifier devised by Zenith Radio Corp., for use in ultra high frequency and microwave radio receivers is reported to have a noise figure of about 1 db and a gain up to 30 db.

Extension of the effective range of military defense radars and those of missile and earth satellite tracking systems is expected with the new tube.

Officials report that the amplifier is completely unilateral and unconditionally stable. It is based on the concept that a certain mode of motion on an electron beam (the fast wave) permits interchange of input signal and beam noise in a coupler. An electron gun generates beam of about 35 µamps which drifts at very low velocity, corresponding to only 6 v, along the lines of a 200 gauss magnetic field. Input and output couplers are tuned to the center of the signal frequency band, about 560 mc. The electron beam enters the input coupler with a

#### Solid State Amplifier

Basic improvement in a parametric microwave amplifier promises to offer particular advantages in the range of frequencies from 1000 to 10,000 mc and higher.

The RCA development uses an experimental germanium diode to detect an incoming high frequency signal. Associated with the diode is either a transistor or a "pencil-type" tube oscillating at a lower frequency to provide a "pumping" action which amplifies the signal.

Parametric microwave amplifiers previously have been considered impractical for operation at these frequencies because they have required a pumping frequency higher than that of the signal to be amplified. RCA scientists reported that the new device has the capability of amplifying extremely weak signals which frequently are drowned out by operating noise in present types of equipment. They indicated that the new device requires a power supply of only a fraction

Inside view of fast wave parametric amplifier.

certain amount of random motion. The fast wave component of this motion is given up to the input coupler and transformed into heat in the resistive portion of the signal source. At the same time, the beam absorbs signal energy and carnies it in the form of a fast wave, thus interchanging beam noise and input signal.

Spiraling electron motion which carries the signal is amplified during passage through the quadrupole electrode, a structure that resembles the stator of a four-pole generator. A highly non-homogeneous transverse electric field of four-fold symmetry is produced. The quadrupole is connected to the "pump" which supplies about 10 mw at about 1120 mc.

One component of the alternating non-homogeneous field pattern in the quadrupole appears to revolve in synchronism with the spiraling electrons. This causes the radius of their orbits to increase or decrease exponentially, depending upon their phase at the instant of entry. When the two processes are averaged, exponential growth always outweighs exponential decay and gain results. The gain for which the pump power is adjusted has no effect on the bandwidth. The tube measures four inches in length.

Application has been made for patent rights and commercial production will be undertaken "as rapidly as possible."

## ifier Promises 1000 to 10,000 mc Operation

of a watt, compared to a hundred watts or more for present conventional microwave amplifiers. Moreover, extremely low temperatures needed in maser operation and magnetic fields for traveling wave tubes are not required by these solid-state devices. The amplifier can be packed into a space of four cu in., permitting its ultimate use in missiles, satellites, and airborne equipment. Principal application of the new technique lies in the centimeter and millimeter wave re-

gions, where higher-frequency local oscillator power for pumping is difficult to obtain.

K. K. N. Chang and Stanley Bloom of the RCA Princeton Labs who developed the new technique stated: "The parametric amplifier principle has been placed in an entirely new light, and the technique promises to push back the present practical frequency and signallevel limitations to microwave communications."

#### TWT Maser Operates at 25 mc; Shows 23 db Forward Gain

Bell Laboratories developmental traveling wave, non-regenerative maser amplifier operates at 25 mc with a forward gain of 23 db according to test reports.

This maser offers high stability and unilateral gain. At 25 mc, a reverse loss of 29 db was noted. The non-reciprocal device is quickly tunable over the 350 mc bandwidth, a noteworthy figure com-

pared to cavity type masers which are limited in bandwidth and gain by the microwave cavity circuit. Maser material used in the new device is ruby. Expectations are that this amplifier will be initially used in ground based equipment.

This development is another result of Bell Labs intensive investigation of microwave amplifiers.

#### **BEHIND THE NEWS**

#### Study Radiation of

Characteristics of magnetic ma terials exposed to a radioactive source can be measured by a new device. The instrument, a remote controlled "torque magnetometer." is used by Westinghouse Electric materials engineers to measure and record the torque exerted on a thin disk of magnetic material sus pended in the gap of an electro magnet. As the sample of material i rotated, the torque exerted on the disk changes according to the change in magnetization of the ma terial. This is measured by the torque magnetometer and automati cally plotted on a strip chart re corder. The result is a curve of torque versus angular position o the disk, with respect to the direc tion of the applied field. The infor mation can then be used to deter mine the "anisotropy constants"-

#### Light Measure

Far more precise measurement of magnetic forces originating in side the earth and in outer space may now be possible with the perfection of a new measuring method by the Department of Commerce

A beam of light is sent through a tube containing a small quantity of vaporized rubidium. The manner in which the light is absorbed indicates the strength of the magnetic forces. The explanation is that the absorption of light depends on the spinning of the electrons in the rubidium molecule, and the spin in turn is controlled by the magnetic forces, or field.

According to Commerce Dept officials, instruments embodying the principle will be simple, highly miniaturized, and capable of measuring very small magnetic fields"perhaps one billionth of the magnetic force developed by the motor

## IN GENERAL ELECTRIC'S **NEW PANEL INSTRUMENTS**

#### DISTINCTIVE APPEARANCE

Clean-line design sparkles with functional new beauty-adds a distinctive touch to your finest switchboards and panels. Big border-to-border scale is framed in aluminum for better color blending. Design innovation creates the illusion of bigness, yet they fit into the same useable space as old style instruments.

#### **EXCELLENT READABILITY**

BIG LOOK styling provides up to 28% increase in scale length over types replaced. Easy-to-read numerals cannot be obscured by the slim, tapered pointer. Clear raised window allows natural light to flood scale area, keeping shadows out.

#### RELIABLE OPERATION

Self-shielding: Exclusive moving-magnet mechanism and the core-magnet mechanism can generally be mounted on magnetic or non-magnetic panels without special calibration.

Completely Sealed: All cases are sealed with neoprene gaskets to protect internal parts from dust, dirt, and water for extra-long, trouble-free operation. D-c movements and a-c iron-vane movement are accurate to within  $\pm 2\%$  of full scale value.

For complete information contact your nearby G-E Apparatus Sales Office or Distributor; or write for bulletin GEA-6678A, Section 582-31, General Electric Company, Schenectady 5, N. Y.

Progress Is Our Most Important Product

#### BEHIND THE NEWS

#### All Quiet on Any Front With New Army Earphone

Development of an experimental electronic earphone, that shuts out loud noises which interfere with combat communications was announced by the Department of the Army.

The artificial quiet is created by adding more noise with a miniature microphone in the special earpiece to create a second noise, just as loud, but opposite in phase. This phase opposition greatly reduces the noise level. The earphones, which are expected to have many commercial as well as military uses, resulted from early noise reduction experiments conducted at RCA, Camden, N.J. and application of the concept to earphones was conceived at the U.S. Army Signal Engineering Laboratories, Fort Monmouth, N.J.

**Experimental earphones** contain a tiny circular microphone (lower disc) which picks up noise that leaks through ear cushioning. It then produces a second noise opposite in phase to first which cancels the first in large measure, and produces an artificial quiet.

#### **Transistor Chart Correction**

Our 1958 listing did not include many Texas Instruments Inc. and General Electric Co. types that originally appeared in our 1957 chart.

A complete listing of the missing transistors along with their characteristics will appear in the October 1st issue.

#### Japanese Atomic Clock Uses Ammonia Gas

Second atomic clock developed in Japan again uses ammonia gas rather than the cesium beam of English and American clocks.

Although the United States and United Kingdom clocks provide far greater accuracy, this Japanese design marks the success achieved in controlling the molecular vibrations of ammonia. The announced accuracy of the British clock is two parts in 10,000 million, or an error factor of one second each 150 years. Atomichron, the U. S. product, has an accuracy of 5 parts in 10,000 million, or an error factor of 1 sec every 150 years. The Japanese clock has an error factor of one second in 50 years. Japan's first atomic clock, developed 15 months ago, had an error factor of one second in 15 years.

"American and British physicists consider ammonia gas unsuited for atomic clock use since they found the vibration frequency of the ammonia molecule was not as constant as that of the cesium atom," said Dr. George Michio Hatoyama, physicist at the Government's Electric Laboratory who developed both Japanese atomic clocks.

They found the frequency varied from time to time according to such conditions as room temperature, gas pressure, and gas purity, he explained.

The Japanese physicist learned to control these factors to get the consistency of frequency required. This latest development promises improved models in the not too distant future.

Dr. George Michio Hatoyama and his atomic clock.

## WASHINGTON REPORT

Herbert H. Rosen

#### Wanted: Research Ideas For Tubes and Parts

A \$34 million program is about to be initiated by the Department of Defense aimed at improv. ing electron tubes and electronic parts. Chief coordinator for the program is the Director for Electronics, J. M. Bridges, in the Office of the Assistant Secretary of Defense for Research and Engineering. The contracts for the separate projects will be awarded by the military services. Below is shown how the funds, in millions, are apportioned among the three services.

Army	Navy	Air Ford	
\$3.536	\$1.631	\$2.093	
1.915	1.770	1.840	
	\$3.536	\$3.536 \$1.631	

Bridges' office is seeking new ideas for tubes and parts. A thorough study is being conducted of existing projects by the advisory groups on electron tubes and electronic parts. These advisory groups will make the next-to-final decision on projects submitted to them by the military services or by private companies with ideas needing support. Final approval for each project, of course, rests with Bridges and his staff.

This program has only recently been augmented by \$12.8 million from the Defense Secretary's emergency fund. However, if proven as successful as anticipated, similar amounts of money-\$34 million, total-will be budgeted for the next five years. Therefore, year-end progress reports will figure heavily in the future of the whole program.

#### Tacan for Civilian Planes Opposed

Opposition to the costliness of Tacan was offcially voiced recently by the Air Transport Association, spokesman for the scheduled airlines. AIA has come out strongly for a combination of VOR and a system called DMETdistance measuring equipment with certain Tacan capability. The association contends that DMET is considerably less expensive because it eliminates the need for the azimuth antenna in the Tacan system.

ATM claims that by taking this position it is informing the manufacturers of short range navigation equipment of the future requirements of the airlines. However, being opposed to something, in this case, does not make ATA for something else. Its technical staff is still seeking the "ideal" navigation system. They will welcome any suggestions, whether they be doppler or conventional radar navigational aids.

Meanwhile, the major R & D agency concerned with the problem, the Air Modernization Board, continues its search for new ideas and equipment. Development contracts for terminal and enroute equipment systems have gone to General Equipment Laboratories. And the AGACS-airground-air communications systèm-contract has been awarded to RCA. Twelve other companies share in \$12.6 million worth of AMB contracts. Very shortly another contract will be awarded for the development of a system to aid in ground approach and touch down of civil airplanes.

One company very much interested in this area is Bell Aircraft. This company has successfully demonstrated the use of its automatic landing system with a Boeing 707 jet transport. Previous tests with the Navy have led to the tentative acceptance of the Bell system for carrier aircraft.

Obviously, an all-weather automatic landing system is possible with the technical capability at hand. Even back in 1949, the CAA demonstrated capability with its ILS. But simple economics may impose obstacles that will not be as easy to hurdle.

AMB estimates that the \$6 billion airways we have today are closed down 15 per cent of the time because of bad weather. It costs the airlines about \$6 million each year because of resulting

However, it would cost about \$900 million to equip all of the air terminals with all-weather equipment. On top of this figure are added the costs for brick and mortar.

#### **ARPA Discloses Projects**

Roy Johnson, Director of the Advanced Research Projects Agency, recently announced the types of programs his agency hopes to carry and the money allotted to each. Among these are: Anti-ICBM, \$157 million. The Nike Zeus portion of the project is budgeted for \$57 million. Communications, \$9 million. Navigation, \$1 million. Components development, \$10 million. Satellite tracking, \$17 million. Lunar probes and associated ground scanning equipment, \$14 million. Reconnaisance satellites, \$186 million. Solid propellants development, \$20 million. Exploratory research in related fields, \$13 million. Maximizing payload capability, \$6 million. And man-inspace experiments, \$50 million.

No stoop, no squint, no painful nagging backache\*

## **Buy this Testmobile and tilt** your'scope so you can read it!

Obsoleting all previous concepts in one brilliant breakthrough, -hp- engineers have achieved the ultimate device-the revolutionary 115A Oscilloscope Testmobile. Employing the radical Supermarket Cart principle (first described 1906 by A. and P.) -hp-115A actually tilts an oscilloscope so you can read it, and lets you push it from place to place! Scope may be tilted up to 30° in 71/2° increments; heavy chromed tube steel construction; big, locking, rubber-tired wheels; removable bottom basket; size 40" high x 23" wide x 29" deep, folds for shipment or storage; lightweight, only 28 lbs., \$80.

\*with thanks to our friends at Philco and Anacin

Still further probing the Unknown, -hpengineers achieved the -hp- 116A Storage Unit and 117A Storage Drawers. The 116A is a sophisticated cube known as a "box." It holds up to 3 plug-in units for -hp- 150A/AR 'scopes; prevents dust and elbows in the circuitry. Yours for \$22.50. The 116A also holds up to three 117A drawers which in turn hold tools, solder, components and bubble gum. -hp- 117A, a modest \$10.

**HEWLETT-PACKARD COMPANY** 4959K Page Mill Road . Pale Alte, California, U.S.A.

Cable "HEWPACK" . DAvenport 5-4451 Field engineers in all principal areas

**Besides Testmobiles,** -hp- makes oscilloscopes, too!

-hp- 150A/AR - to 10 MC Automatic trigger, directreading; plug-ins providing dual trace or differential input; or high amplification. -hp-150AR (rack) \$1,200. -hp-150A (cabinets) \$1,100.

-hp- 130B/BR - to 300 KC 1 mv sensitivity, similar X/Y amplifiers, direct reading, automatic trigger, X5 magnifler, balanced on 6 most sensitive ranges. -hp- 130B (cabinet) or 130BR (rack), \$650.

-hp- 120A/AR - to 200 KC Sweeps 1 µsec/cm to 0.5 sec/ cm; X5 sweep magnifier, automatic trigger, high sensitivity calibrated vertical amplifiers, regulated power supplies. -hp- 120AR (rack mount, 7" high) or 120A (cabinet) \$435.

## PERMITS ENCAPSULATING, IMPREGNATING, OTHER PROCESSING . . . WITH NO CHANGE IN MAGNETIC VALUES

Newest development in cores for magnetic amplifier applications is the Westinghouse Polyclad hermetically sealed Hipermag core.\* Polyclad insulation is applied over a new specially designed aluminum box housing the core. This hermetically seals the core and allows encapsulating, casting or impregnating—without altering magnetic properties . . . Eliminates magnetic amplifier rejects caused by changed magnetic values.

Tested for all environmental conditions, Polyclad insulation is suitable for high temperatures, protects against humidity and high-voltage stress, provides high insulation strength, with breakdown values up to 3000 volts.

Polyclad coating eliminates the need for core taping; makes possible reduced insulation cost. Rounded corners prevent shorting wire to core, allow winding directly on the core.

These cores are supplied in special sizes or in standard AIEE sizes, in one-, two-, or four-mil oriented nickel-iron alloy Hipernik® V and in one- or two-mil 4-79 Permalloy. Complete listing in Westinghouse publication 44-720.

Hermetically sealed Hipermag cores are available in production lots with normal delivery. All Hipermag cores are tested — by Roberts constant-current, flux reset technique, or to your specifications.

For more information about Polyclad hermetically sealed Hipermag cores and other Hipersil® or Hipermag cores, call your Westinghouse representative . . . or write Westinghouse Electric Corporation, P.O. Box 231, Greenville, Pennsylvania.

## Psychiatrists Plagued by "Read Papers", Too

Editor, The American Journal of Psychiatry

"Listening to papers" is one of the many trials and tribulations of a psychiatrist—by far not the least; and the pages of professional magazines are customarily reserved for the very same people who "read papers." Time and again I have sworn to myself never to attend another meeting or convention and never to listen to another paper—ever! But I end up like the man who stated: "To stop smoking is the easiest thing in the world—I have done it hundreds of times." And so, sooner or later, I find myself at the receiving end of a "paper."

I always enjoy listening to a man who has something to say. But if a speaker has something to say—why does he not just go ahead and say it—why has he "to read a paper?" Psychiatrists who habitually inquire into the "why?" of human behavior seem to shun inquiries into the motivation of "paper-reading"—a rather amazing fact if one considers the usual intensity of their professional curiosity.

"Speaking" is one thing, "reading a paper" is something else. The former has its place as a valuable experience in interpersonal relationship; the latter is a rather irrational act, considering that the listeners are most likely all able to read themselves quite well, illiteracy being rare among psychiatrists. If the "reader of a paper" had the voice and the skill of a Charles Laughton, listening might be pleasurable. More likely, however, the reading is a stammering, fumbling, or monotonous production of complicated sentences, constructed for careful reading in one's own studio, but not intelligible at the high speed at which they are thrown at us at the meetings.

A few papers are rich in value—most of them are not. I have listened to many papers of considerable length, the pertinent content of which could have been summarized in a few sentences...

Others leave us with the strong impression that the speaker had "to give a paper" for some reason or other, so that the reading of the paper is an end in itself and no longer serving any other pur-

What does the listener get out of his attendance? A short while ago I attended a lecture given to teach techniques in group therapy. After the lecture one of my co-listeners, duly impressed by the famous name of the speaker, felt moved to give vent to his admiration of the performance. Since I myself felt disappointed I raised the question "what, if anything, did we learn?" Only then did several others dare to show their own disappointment. Only then did one after the other object that we had heard nothing but well known generalizations. The eulogist withdrew behind the statement, that he had enjoyed the strong feeling: "Here is a man who is a master of a difficult technique!" I felt I did not have to come from far away to convince myself that some men master a technique well-I was aware of that fact. I came to learn . . .

1958

Rarely do we meet a speaker who "speaks." If that happens it is an enjoyable experience provided he has something to say. Even if he occasionally should get mixed up in his syntactical constructions, if he has occasionally to stop and think for a moment, or to check his short notes before going on, even if he has sometimes difficulty to find the right word, I still prefer him thousand times to the reader of a smooth paper; and so I think would most of us. For spoken anguage is the natural means of oral communication, as written language is designed to be read. Thoughts that a man can express in free speech can usually be understood by attentive listening; papers sometimes remain obscure even when one reads them slowly.

Why then are such "speakers" so rare? It seems that few men can handle their anxiety in facing an audience and that a rigidly fixed and prepared manuscript is their only defense.

There is no doubt a corner in Heaven reserved for us, the listeners, a corner where no papers are allowed to be read . . .

Dr. Hans S. Unger Supervising Psychiatrist Buffalo State Hospital Buffalo, N.Y.

Shortly after our editorial decrying the inefficiency of paper reading at conventions, we chanced to see the Convention issue of *The American Journal of Psychiatry* and Dr. Unger's discerning comments. We asked permission to reproduce them. In granting permission, Editor Farrar included this quote by the late science historian, George Sarton: "In my opinion, the reading aloud of a written paper is a cardinal sin, as deplorable as meretricious writing; it is a wicked procedure, utterly contemptuous of the audience and unfair to it."

## Continental Connector TAPER PIN TERMINAL BLOCKS

**SERIES 145-58** 

SINGLE ROW

# for computer applications

Here is an improved terminal block design with permanently molded-in and precision reamed taper pin receptacles for maximum durability. These receptacles maintain secure electrical and physical contact with AMP Series "53" solderless taper pin. The body is molded of high impact, glass reinforced Alkyd 446 (MIL-P-14E, Type MA160). Other molding materials on request. Taper receptacles are brass, gold plated over silver for low contact resistance.

Continental Connector can supply all types of taper pin blocks and connectors for conventional wiring and printed circuitry in any combination of feed-through shorting or non-shorting terminals. Our engineering department is prepared to cooperate in solving your connector application problems. Write today for technical information.

Developed primarily for COMPUTER APPLICATIONS requiring dual solderless wiring leads for each single contact. The right angle plug is dip soldered to the printed circuit board and mated with the dual terminal socket. Socket terminals are precision machine tapered for AMP "53" solderless wiring. Contact rating 20 millivolt drop maximum at 7.5 amps. Connector rating 500 volts RMS.

Manufactured by Continental Connector Corporation, Woodside 77, N. Y.

## **ELECTRONIC PRODUCTS**

The long experience of The Carborundum Company in the field of ceramic materials bonded at high temperatures, and the specialized facilities of its Globar and Latrobe plants make possible a wide range of quality products for the electronics industry.

#### **CERAMIC RESISTORS**

GLOBAR® resistors are supplied in three broad classifications as described below. Wide experience with many specialized applications insures you of expert engineering assistance.

#### **FIXED, NON-INDUCTIVE RESISTORS**

GLOBAR fixed, non-inductive resistors are available in three types and in a range of physical sizes, shapes and compositions. Type A, carbon composition body has conventional characteristics: low temperature coefficient, low voltage coefficient and normal dissipation capability. Type B, silicon carbide body has a moderate temperature coefficient (negative), moderate voltage coefficient (negative) and normal dissipation capability. Type CX, silicon boron body has a low temperature coefficient (positive), practically zero voltage coefficient and exceptional dissipation capability. Write for Bulletin GR-1.

#### VARISTORS

GLOBAR Type BNR varistors are nonlinear (voltage-sensitive) resistors for voltage control and stabilization applications. They are made from the highest electrical grade silicon carbide, ceramically bonded into disc, rod and cylindrical shapes. Flexible production facilities make possible a wide range of physical sizes, watt ratings and changes of resistance with applied voltage. For details, write for Bulletin GR-2.

#### **THERMISTORS**

GLOBAR Types B, F and H thermistors are non-linear, negative temperature coefficient resistors, available with coefficients from approximately .3% to 5.1% at 25°C. Disc and rod shape bodies may be manufactured in a wide range of sizes to provide desired resistance values, thermal time and dissipation constants and temperature coefficients for a variety of electronic circuits. For details, ask for Bulletin GR-3.

Send to Globar Plant, Dept. CC98, Niagara Falls, N.Y.

## CERAMIC TO-METAL, &

#### CERAMIC PARTS AND METALIZED ASSEMBLIES

CERAMIC PARTS are made of Alumina, Cordierite, Steatite, Magnesia, Zircon and STUPALITH.® These materials provide a range of characteristics that meet practically all conditions of voltage, frequency and temperature. Typical products are coil forms, insulators, vacuum-tube spacers, tubing and a wide variety of precision shapes—plain, ground, metalized or assembled to individual specifications.

METALIZED ASSEMBLIES include terminals and other products in which metal and a special alumina are intimately bonded by an exclusive process to produce a strong, durable, vacuumtight seal. These assemblies withstand exposure to elevated soldering temperatures for long periods. The bond is stronger than the ceramic itself. For details, write to Latrobe Plant, Dept.

DD98, Latrobe, Pennsylvania.

CIRCLE 15 ON READER-SERVICE CARD

Typical examples are shown here. Well-equipped laboratories, modern testing equipment and a staff of quality-conscious experienced engineers are at your service to help on your problems and to design products that will meet the most exacting specifications.

## PARTS, METALIZED ASSEMBLIES, GLASS-COMPRESSION SEALS, AND KOVAR® ALLOY

#### **GLASS-TO-METAL SEALS KOVAR AND COMPRESSION TYPES**

KOVAR GLASS SEALS use an oxide bond between metal and glass. All components have matched thermal expansion characteristics to meet the most exacting standards of vacuum tightness, light weight and high voltage flashover requirements. These are made in all types of single terminal, multi-lead KOVAR glass seals using tubular, solid and special formed leads. Also available are stand-off, strain relief, graded (KOVAR to laboratory pyrex), and special seals for all hermetic sealing applications.

COMPRESSION SEALS are designed to provide the strength, durability and electrical properties required for the most rugged applications. Carborundum's compression seals are thermally pre-stressed and dimensionally controlled for ease of welding or soldering. Choice of tin-nickel-silver or gold plating for appearance and corrosion resistance.

For details, write to Latrobe Plant, Dept. DD98, Latrobe, Pennsylvania.

#### **KOVAR ALLOY** FOR SEALING TO GLASS

KOVAR is an iron-nickel-cobalt alloy especially developed to meet the requirement for the highest quality seals in combination with certain low expansion or hard glasses. It is easily formed. KOVAR seals readily, resulting in chemically-fused oxide bonds insuring ruggedness and permanent vacuum and pressure tightness under the most severe conditions of temper-

ature, vibration and handling.

During twenty-five years of experience many refinements in production have resulted. Stringent laboratory control insures uniform high quality and duplication from lot to lot.

Among the outstanding features of KOVAR alloy are close match in thermal expansivity over the entire operating tem-perature range of high thermal-shock glasses. It provides ease of welding, brazing and soldering, and is capable of being readily plated with other metals, either by electrolytic or chemical methods.

Stocked in a large variety of forms and sizes-sheet, strip, rod, wire, tubing, cups, eyelets and special shapes. Technical service is available to help you solve processing and application problems.

For details, write to Latrobe Plant, Dept. DD98, Latrobe,

## MEET UTMOST PRECISION STANDARDS

When you specify Breeze slip rings, you start with these advantages: you may order custom assemblies built to the most exacting standards, or effect real economies by choosing from Breeze-engineered stock items if they suit your applications. Both kinds can be depended upon for the utmost in precision and performance. As for size, Breeze offers a wide range, from small 2-ring assemblies to 500-ring giants.

Breeze slip rings will handle currents as high as 350 amps at 220 volts and 700 amps overload at 220 volts. Special designs are available for very high voltages, radio frequency requirements, high speed rotation types for strain gage and thermocouple applications.

If you have a problem that slip rings can solve, put it in the hands of our specialists.

Write for detailed literature.

#### Can We Learn from the Russians?

If you've written anything of engineering importance, the chances are the Russians have read it—or will. They don't burden themselves with qualms about using only original thinking. If your design, your innovation, or your research can help them—they won't bother duplicating your efforts. And, if you've written a darned good textbook, they'll use that, too.

This is not accidental. It is the deliberate undertaking of a nation which, in a little over 40 years, has zoomed from semi-feudalism to the status of a leading world power. The All-Union Institute of Scientific and Technical Information of the Russian Academy of Sciences abstracts important scientific and technical papers from all over the world. It has some 2000 translators at work. They turn out an average of 10,000 abstracts a week, and translate the most important articles in full.

It is generally conceded that Russia's policy of monitoring the scientific and engineering output of the world in general, and the United States, in particular, has paid off.

Until Sputnik I, most people didn't feel it was at all important to check Russian developments. The possibility of our learning anything from the Russians was considered remote, if not absurd. But now, government and industry have become increasingly concerned with what the Russians are writing.

#### First Full Book Translation

We, too, have been concerned. Since 1955, we've been publishing abstracts of articles in leading Russian electronics journals. Now, for the first time, we present a full translation of a new Russian book, in serial form. Part 1 begins on page 126.

Nonlinear and Parametric Phenomena in Radio Engineering should help many engineers who view nonlinearity as an unavoidable evil which must be corrected for. These engineers design only on a linear basis, and correct for nonlinearities later. But there are many circuits which depend on nonlinearity—multivibrators, oscillators, switching circuits, etc. And nonlinear elements can actually *improve* linear system performance.

Where the few previous books on the subject reached for the system designer, the advanced researcher, or the mathematician—this one aims squarely at the electronic design engineer—and speaks his language. Information on nonlinear electronics has been available before—in scattered paragraphs, chapters, conference papers—but never in such unified and compact form.

We think this book is a fine introduction, and it helps answer the question, "Can we learn from the Russians?"

#### COLUMN B

NEW resin back STANPAT ELIMINATES GHOSTING, offers better adhesive qualities on specific drafting papers.

#### THE PROBLEM

Some of our longtime customers first called our attention to the "ghosting" problem. Certain tracing papers contain an oil which could be leeched out by the STANPAT adhesive (green back) causing a ghost.

#### THE SOLUTION

A new STANPAT was developed (red back), utilizing a resin base which did not disturb the oils and eliminates the ghost. However, for many specific drafting papers where there is no ghosting problem, the original (green back) STANPAT is still preferred.

## WHICH ONE IS BEST FOR YOU?

Send samples of your drawing paper and we will help you specify. Fill out coupon below:

STANPAT CO., Whitestone 57, N. Y. Phone: Flushing 9-1693-1611 Dept. 51

- Enclosed are samples of the drafting paper(s) I use (identify manufacturer). Please specify whether Rubber Base or Resin Base STAN-PAT is most compatible with these samples.
- ☐ Send literature AND samples of STANPAT.
- Please quote price on our enclosed sketches which we are considering to have pre-printed by STANPAT.

## **Electronically Controllable Bandpass** For I-F Amplifiers

G. W. Clevenger

Bendix Radio Baltimore, Maryland

You can now change the bandwidth of an i-f amplifier merely by varying the bias of a single tube. The change in bandpass can be as high as 20 to 1 in a 30 mc i-f strip. Nor is the on-frequency gain affected. The bandpass shape assumes all intermediate shapes associated with the sharp single tuned and the flat topped, critically coupled cases. And as you will see, the circuit is easy to design.

HERE IS A variable bandpass that simplifies the design of radar and communication networks. The filter can be used in a number of circuits where the bandwidth has to be varied symmetrically around the center frequency. Obvious applications are:

■ In a radar set having a choice of two or more pulse widths;

■ As a replacement for mechanical devices used in certain communications receivers to vary i-f bandwidth:

■ In a search receiver which must search a given band as rapidly as possible, find the desired

+B

signal, and afterwards be insensitive to nearby distracting signals.

#### **Operating Characteristics**

A simplified schematic of the variable bandwidth amplifier is shown in Fig. 1, along with a vector diagram of the phase relationships which hold at the various points.

In the vector diagram,  $e_1$  is used as the reference. Assume a frequency which is on resonance for the two tuned circuits. We find e2 lagging e1 by 90 deg and attenuated by the factor  $G_1$ . The voltage at the plate of  $V_1$  is then 180 deg out of

Fig. 1. Schematic of variable bandwidth amplifier. The phase relationships at different points of the circuit are shown in the vector diagram.

phase with  $e_2$  or at +90 deg. The effect of the second phase shifter is to cause  $e_4$  to lag  $e_3$  by 90 deg, or make e4 again in phase with voltage  $e_1$ . The current  $i_{fb}$  which is caused to flow in the direction indicated, byt the presence of  $e_4$  on the grid of V<sub>3</sub>, constitutes a dynamic pure resistive loading across tank circuit  $Z_1$ . The solid lined vectors indicate only the resonance condition.

Assume a frequency above the natural resonance of circuits  $Z_1$  and  $Z_2$ . The tank circuit  $Z_2$  is now capacitive. Therefore, e3 lags its former position by the angle \$\phi\$, causing a corresponding lag of  $e_4$  behind its former position. The effect of the lagging current  $i_{fb}$  is as if a dynamic resistance and a dynamic inductance had been connected across tank circuit  $Z_1$ .

As circuit Z<sub>1</sub> is also capacitive, since a frequency higher than resonance was assumed, the sign of the inductive susceptance is correct to retune the circuit  $Z_1$  to the new higher frequency. This is the same effect as the tuned secondary interaction with the primary previously noted in the coupled circuit case. Furthermore,  $i_{tb}$  is controllable in amplitude by carrying the gain within the feedback loop, that is, by varying transconductance of V2. The variation of gain within the feedback loop is analogous to mechanically varying the coefficient of coupling between two tuned circuits.

One other feature of the circuit is worthy of mention. The Q of the first coil  $(Z_1)$  sets the minimum bandwidth. Its Q should be made as high as possible, if wide excursions of bandwidth are desired. It is preferable to unload Z<sub>1</sub> as much as possible by inserting a cathode follower between  $Z_1$  and the RC phase shifter  $G_1$ . Adding a small capacitor from cathode to ground on the cathode follower allows slightly more than 90 deg phase shift in  $G_1$ , to compensate for the slightly less than 90 deg shift in the simple RC shifter  $G_2$ .

Care must be exercised not to exceed the stable gain of  $V_1$ . As the bandwidth is narrowed, dynamic loading across  $Z_1$  decreases until  $V_2$  is cut off.

The performance of the variable bandwidth i-f amplifier is given in Fig. 2 in terms of bandwidth versus bias on  $V_2$ . Fig. 3 is a multiple exposure photograph of the bandpass of the circuit with several values of bias on  $V_2$ .

#### **Constant Gain Feature**

tion

ELE

Referring to Fig. 1, we can immediately write the expression for the impedance paralleling  $Z_1$ due to feedback.

$$Z_{fb} = \frac{1}{G_1 G_2 G_{m_2} G_{m_3} Z_2}$$

The parallel impedance of  $Z_1$  and  $Z_{fb} = Z_{1p}$

## TUNG-SOL POWER TRANSISTORS IMPROVED THREE WAYS BY:

## NEW

# COLCELUL SELAL

Tung-Sol's new true cold-weld seal represents a major advance in transistor technology. An exclusive Tung-Sol development, cold-weld sealing increases TO-3 outline package efficiency and brings designers a threefold bonus in over-all transistor performance.

Improved thermal qualities. The cold-weld process produces a hermetic, copper-to-copper seal and makes possible a 100% copper transistor with thermal properties superior to previous high power types.

Improved reliability. Cold-weld encapsulation eliminates heat damage, "splash", and heat-caused moisture that can impair transistor performance.

Longer efficient life. Even through temperature fluctuations that cause "breathing", the cold-weld seal stays vacuum-tight, moisture-proof—result of actual integration of the copper molecules during sealing.

Tung-Sol power switches with the new cold-weld seal withstand the most rigid combination of tests given any transistor—the 100 psi "bomb" immersion test and the critically sensitive Mass Spectrometer leak test. Further, they meet all military environmental requirements. For full data on the improved Tung-Sol types . . . to fill any transistor need, contact: Semiconductor Division, Tung-Sol Electric Inc., Newark 4, New Jersey.

Assume

 $Z_1 = 27 \text{ K}$   $Z_2 = 3.3 \text{ K}$   $G_{m_1} = G_{m_3} = 9000 \ \mu\text{mhos}$   $G_1 = G_2 = 0.2$   $G_{m_2}$  varies from 0 to 9000  $\mu$ mhos

The computed values of gain at resonance when  $G_{m2}$  is varied, Fig. 4, shows that the gain approaches 5 asymptotically as  $G_{m2}$  approaches large values.

Another important result is that even with the transconductance reduced to 100 µmhos, the gain through the variable bandwidth circuit has dropped only 3.81 or not quite 3 db. This result is not surprising because what is actually happening is a gain variation within a negative feedback loop.

It is desirable to vary the transconductance of the tube  $V_2$  to take advantage of the constant gain feature. If, however, the choice has been made to vary both  $G_{m2}$  and  $G_{m3}$  in a similar manner, eq 1 reduces to an analogous equation describing the action of two tuned, coupled circuits with a continuously variable mutual inductance.

#### **Transfer Impedance**

To make a comparison between this circuit and a double tuned circuit, the concept of transfer impedance is introduced. Transfer impedance in the latter case is defined as that impedance which, when subjected to the current which flows in the tuned primary, gives a voltage equal to that which appears across the tuned secondary.

The equivalent transfer impedance from  $\mathbb{Z}_1$  to  $\mathbb{Z}_2$  is gotten from eq 1, by dividing out  $G_{m1}$  and substituting impedance forms. Then

Fig. 4. Computed variation of gain versus bias on tube  $V_2$ .

$$Z_{12} = \frac{G_1 G_{m_2} R_1 R_2}{G_1 G_{m_2} G_{m_3} R_1 R_2 + 1 + j (Q_1 + Q_2) n - (Q_1 Q_2) n^2}$$
(2)

The transfer impedance Z<sub>12</sub> of a double tuned coupled bandpass circuit is<sup>2</sup>

$$Z_{12} = \frac{jS\sqrt{R_1 R_2}}{(1 + S^2) + jv\sqrt{b+2} + (jv)^2}$$

$$S = K\sqrt{Q_1} \, \overline{Q_2} \qquad K = \sqrt{L_1 \, L_2}$$

$$b = \frac{Q_1}{Q_2} + \frac{Q_2}{Q_1}$$

$$v = \sqrt{Q_1 \, Q_2} \left( \frac{W}{W_o} - \frac{W_o}{W} \right)$$

$$v = \sqrt{Q_1 \, Q_2} \left( \frac{w}{w_o} - \frac{w_o}{w} \right)$$

For convenience we let  $n = \left(\frac{w}{w_o} - \frac{w_o}{w}\right)$ .

Therefore,

$$n = \frac{v}{\sqrt{Q_1 Q_2}}$$

and the third term in the denominator of eq. 2 may be written as  $jv (Q_1 + Q_2)$ , which in turn is  $\sqrt{Q_1 + Q_2}$ 

equal to  $jv\sqrt{b+2}$  in eq. 3.

Similarly, by substituting the expression for v in the last term in the denominator of eq 2 we can write it as either  $-v^2$  or +(jv).

If we now assume a correspondence of S to  $G_{m2}$   $G_1$  in eq 2 by restricting  $G_1$  to equal  $G_2$ , and  $G_{m2}$  to equal  $G_{m3}$ , we can rewrite eq 2 in the same way as eq 3. It should be noted that S in eq 3 is the only term containing K, the coefficient of coupling, assumed variable. Similarly the equivalent term,  $G G_m \sqrt{R_1 R_2}$  is the only one with a variable term, namely  $G_m$ . We have therefore shown that by varying transconductances only, the exactly equivalent function to varying the coefficient of coupling between two coils has been performed. As was previously noted, however, the advantage of constant gain with varying bandwidth when only  $G_{m2}$  is varied, makes this desirable, as shown in Fig. 3.

## DEFEND

Today, creative engineering at Hughes is on the move to DEFEND . . . to counter the threat of aggressive action with electronic speed and precision.

Hughes in Fullerton, California is now creating these systems for total defense:

ELECTRONIC SCANNING RADARS, with beams that provide three-dimensional protection.

dreds of aircraft and store the shifting tactical situations for high-speed assignment of defense weapons.

ELECTRONIC DISPLAY SYSTEMS which present tactical information in symbolic or language form.

Also under development are new three-dimensional radar systems for installation on surface and subsurface naval vessels. Study programs have been initiated in radar, computers, displays and integrated defense systems.

To further these studies, creative engineers and physicists are now needed. These positions promise unusual reward and opportunity for growth. Inquire further . . . for information write to Mr. L. C. Wike at the address at right.

## Design Curves for

T. R. Nisbet

Electronic Research Engineer
Lockheed Missile Systems Development
Palo Alto, Calif.

# Stabilizing Transistors With Thermistors

A popular contributor to ELECTRONIC DESIGN, Mr. Nisbet again demonstrates his ability to make life easier for designers with another set of invaluable design curves. Here is a handy means of rapidly selecting thermistor values for transistor temperature stabilization.

TEMPERATURE compensation of transistors can readily be accomplished with thermistors. It is often a problem however, to select the appropriate thermistor values for the desired compensation. Using a series of curves presented here, derivation of thermistor values to counteract the variation in saturation current  $(I_{co})$  of germanium transistors becomes a simple matter. Silicon transistors can be accommodated to some extent in the same design curves. The thermistor curves can also be used for the compensation of many calculated or experimentally determined variations.

Variation of collector current  $I_{co}$  with temperature for a transistor (either germanium or silicon) is given by

$$I_{co\ (T_1)} = I_{co\ (T_0)} \ \epsilon^{0.075\ (T_1 - T_1)}$$

Thermistor resistance is expressed by

$$R_{TH\ (T_1)} = R_{TH\ (T_0)} \epsilon^{-\beta} \left(\frac{1}{T_0} - \frac{1}{T_1}\right)$$

where temperatures are in deg K and  $\beta$  is a constant of the material, usually valued between 3400 and 4000.

The two exponentials are of different orders, and cannot be directly matched. It can be shown, however, that if the thermistor is placed between the base of the transistor and ground in Fig. 1,

a resistance parallel with  $R_{TH}$  is required—both comprising R—but no series resistance. Some bleed current  $(I_{bl})$  is assumed.

The family of curves, Fig. 2, 3a and 3b permits a suitable combination of current and resistance ratios to be found so that the base is maintained at constant voltage, V, throughout the required temperature range. The current curves depict the combined current  $I_{bl} + I_{co}$  when  $I_{bl}$  is a specific multiple of  $I_{co}$  at 25 C. The thermistor curves show the combined conductance of the thermistor and shunt when the thermistor at 25 C is a specific multiple of the shunt resistance. The

**Fig. 1.** The thermistor forms part of R. Currents flow as in (b), so that the current in R is  $l_{be} + l_{co}$ 

curves are all normalized at different levels (to facilitate comparison) and drawn on logarithmic ordinate scales, with a common temperature scale of abscissae.

Since the logarithm of current minus that of conductance equals that of voltage, the curves can be matched directly against each other. The matching process consists of placing the thermistor curves (or a tracing of the curve of interest) on top of the current curves and moving them up and down, keeping the temperature scales coincident, until a pair is found which match each other over the desired temperature range. From the ratio  $I_{bl}/I_{co}$ , the current in the branch can be determined, and from the voltage across the branch (V, Fig. 1) the combined resistance can be calculated. The thermistor ratio  $R_{TH}/R_S$  then enables the precise values of thermistor and shunt resistance to be stated.

Example 1. A 2N43 amplifier (Fig. 4) with  $I_{co}=7$  μa at 25 C is to be stabilized from -30 C to +80 C. Comparison of the curves shows a reasonable match occurring between  $R_{TH}=10$   $R_{S}$  and  $I_{bl}=50$   $I_{co}$ , as shown in Fig. 5. The current  $I_{bl}$  plus  $I_{co}$  (Fig. 4) at +25 C is therefore 51 x 7 μa. If a voltage of 4 v is to be maintained across the parallel branch of  $R_{TH}$  and  $R_{S}$ , a combined resistance of 4/357 x  $10^{-6}$  ohms is required. With  $R_{TH}=10$   $R_{S}$ , a shunt of 10.2 k  $\Omega$  and a thermistor of  $\beta=3450$  K and  $R_{TH}=102$  k  $\Omega$  at 25 C are obtained.

Before calculation of specific values is actually carried out, several important details can be estimated directly from the curves if desired. By measuring the deviation against the scale on the left of Figs. 2 and 3, the matching, as shown in Fig. 5, is seen to be 10 per cent off at -30 C and +80 C, correct at 32 and 70 C, 3 per cent off at 25 C and 7 percent off at 52 C. The total current  $I_{bl} + I_{co}$  has risen at +80 C to 1.6 times its room temperature value, or 560  $\mu a$ . (It is assumed that the variation of  $V_{be}$  is negligible in this example.)

#### Effect of Mismatch

In the circuit of Fig. 4, it is probable that between base and ground the estimated voltage mismatch of  $\pm 10$  per cent could be tolerated. The same might not be true, however, if the emitter-to-ground voltage is fixed, since the mismatch could result in almost  $\pm 10$  per cent of  $[I_{bl} + I_{co}]$  variation in  $I_b$ . From Fig. 5, this variation can be estimated at  $\pm 0.1 \times 1.6 \times 7 \times 51$ , or  $\pm 56 \mu a$  change in base current. While the nature of the mismatch is a function of the associated circuitry, its magnitude can be assessed directly from the graphs by measuring the mismatch against the logarithmic vertical scale on the left of both Figs. 2 and 3.

**Fig. 2.** Current curves which are superimposed on the thermistor curves (Fig. 3) to enable a matching pair to be selected for the required temperature range. Selected ratio of  $l_{be}/l_{co}$ , together with V, Fig. 1, give the 25 C value of the current in branch R of Fig. 1.

Fig. 3(a) Curves for thermistors of  $\beta = 3450$  ( $R_o/R_{50}$   $_C = 7$ ). The selected curve gives the ratio  $R_{th}/R_s$  at 25 C; their parallel value is already known (Fig. 2) and their individual values can therefore be calculated.

Fig. 3(b) Curves for thermistors of  $\beta=3900$ , i.e. whose resistance at +50 C is 9 times the resistance at 0 C.

#### **Production Spread**

In the majority of germanium transistors, the production spread of  $I_{co}$  is quite broad. In a typical case, the 2N43,  $I_{co}$  may equal anywhere from 1  $\mu$ a to 15  $\mu$ a at 25 C. Plainly, the best possible temperature compensation in such a case will leave a possible error of almost half the value that  $I_{co}$  may reach at the upper limit of temperature. A wide range of thermistor values can be found which give adequate compensation.

If, by selection or through the use of a low collector voltage, the spread of  $I_{co}$  can be restricted (in this example, say 3.7 to 7.5  $\mu$ a at 25 C), thermistor compensation improves.

#### **Eight Rules for Using Graphs**

The rules which follow refer to the construction and interpretation of a matching graph such as that for Example 2, Fig. 6 (below).

- (1) As a preliminary guide, use the geometric mean of the production spread of  $I_{co}$  at 25 C, i.e. the square root of the product of high and low limits.
- (2) By tracing or by visual simulation, superimpose the family of thermistor curves upon the current curves, keeping the 25 C verticals coincident, and find a pair which approximately match over the required temperature

range. Note the ratios  $I_{bl}/I_{co}$  and  $R_{TH}/R_{S}$ . Calculate  $I_{bl}$ .

- (3) As in Fig. 4, trace the portion of the temperature scale which is of interest, extending it if necessary to the left to include —30 C or the temperature at which both thermistor and current curves become horizontal. Draw the verticals representing 25 C and the upper and lower temperature limits.
- (4) Using  $I_{bl}$  as calculated in (2), find the ratio of  $I_{bl}/I_{co}$  at the upper and lower limits of the production spread of  $I_{co}$ . Draw these in the tracing, using an arbitrary horizontal line (AB, Figs. 5 and 6) to represent the common convergence of the two curves. The area between the two curves may be shaded, as in Fig. 6, to represent all possible values of  $I_{co}$  over the temperature range.
- (5) Decide from circuit considerations to what extent the permissible variation should be taken up as an increase and decrease respectively in  $I_b$ , and translate this into terms of the desired point of perfect match at high temperature. In most cases, the geometric mean, half way between the upper and lower limits in the tracing (see Fig. 6), will be used, so that the matching error for a transistor at one limit of the production spread will be

the same as that for one at the other limit.

- (6) With 25 C verticals coincident, trace the thermistor curve (see (2) above) so that it passes through the point of perfect match at high temperature.
- (7) Place the tracing over the log scale of Fig. 2, and, with one point at the scalemark 1, measure in a vertical direction the mismatch ratio at any temperature of interest. The mismatch at cold temperatures will normally be much less than that at high temperatures. Note that a new value of  $R_{TH}/R_S$  may be selected, if desired, provided that the mismatch at the cold temperature limit does not exceed that at the high temperature limit.
- (8) If desired, use the horizontal line of convergence of the current curves (AB) to represent  $I_{bl}$ , and set the logarithmic vertical scale to coincide with it. This gives a current scale, as illustrated in Fig. 6, from which  $I_{bl} + I_{ee}$  can be read for any desired temperature.

Example 2. The transistor of Example 1 is to be matched over 0 C to +110 C for an  $I_{co}$  spread of 3.7 to 7.5  $\mu$ a. Referring to the rules enumerated above, (1)  $\sqrt{3.7} \times 7.5 = 5.3 \mu$ a; (2)  $R_{TH} = 50 R_8$   $I_{bl} = 700 I_{co}$ ; (3)  $I_{bl} = 3710 \mu$ a; (4)  $I_{bl} = 1000 I_{co}$  and  $I_{bl} = 500 I_{co}$ . The curve is constructed as in Fig. 6. Mismatch ratios are measured by placing

## Keithley electrometers for every dc laboratory test

#### Model 610, line-operated, 59 ranges

The Keithley 610 Electrometer is a laboratory workhorse, doing the work of several instruments. It covers the extreme spans of dc voltage, current, and resistance tabulated below, and is a useful preamplifier as well. It has precise gains to 1000, a dc to 500 cps bandwidth, and 10-volt and 1-ma outputs. Input resistance of the 610 is selectable from one ohm to over 10<sup>14</sup> ohms. It checks its own resistance and voltage supply standards. Zero drift is comfortably within 2 millivolts per hour after warmup.

#### Model 600, battery-operated, 53 ranges

The Model 600 is a small, portable, battery-operated sister of the 610. Its many ranges also are tabulated below. Like the 610, its input resistance may be varied from one ohm to over 10<sup>14</sup> ohms, permitting an optimum balance of low circuit loading verus minimum pickup. Output is sufficient to drive potentiometric recorders directly, with a dc to 100 cps band-width, and zero drift is within 2 millivolts per hour. The 600 will check its own batteries; minimum battery life is 500 hours.

#### Need a few specials?

Recent Keithley developments include instruments for the Navy's Vanguard, for Army research balloons, and for Air Force research missiles. Your special problem will receive a prompt reply.

CIRCLE 22 ON READER-SERVICE CARD

the tracing over the log scale on the left. It can be seen that  $R_{TH}$  lying between approximately  $35~R_{S}$  and  $65~R_{S}$ , the percentage error throughout the temperature range is equal to or less than that at  $+110~\mathrm{C}$ . (Note:  $110~\mathrm{C}$ , though beyond the temperature rating of the 2N43, was used in order to facilitate illustration of this example.) For  $4~\mathrm{v}$  base-to-ground, at  $25~\mathrm{C}$ ,  $R_{TH}$  |  $R_{S}$  =  $4/3.705~\mathrm{k}$   $\Omega$ , and from (2)  $R_{S}$  =  $1080~\mathrm{x}$  31/30 =  $1117~\Omega$ .  $R_{TH}$  =  $32.5~\mathrm{k}$   $\Omega$  at  $25~\mathrm{C}$ .

Because of the inherent probable mismatch at the upper temperature, the precise ratio of thermistor to shunt resistance in circuits such as Fig. 1 is seldom very critical. However, for matching a transistor of known  $I_{co}$ , or for matching to a lower temperature than the 114 C used in Example 2, Fig. 5, the graphical method can supply the appropriate degree of accuracy.

limit

#### **Silicon Transistors**

In silicon transistors,  $I_{co}$  is generally of a low value, but an additional significant temperature variation takes place in the base-to-emitter voltage. The graphs are not intended for use with silicon transistors, but if the base-to-emitter voltage change is taken into account, the same curves may be used.

**Fig. 4.** Typical temperature stabilization problem (see Example 1).

Fig. 5. The selected design curves, superimposed, give a picture of the matching of Example 1. The extent of the mismatch is measured on the vertical log scales of Figs. 2 or 3.

Calculated or experimentally derived resistance values over a temperature range can frequently be synthesized using the thermistor curves of Fig. 3. In a typical circuit, it was found that, across a 2 k  $\Omega$  resistor, compensation ranging from  $\alpha$  to 10 k  $\Omega$  was required in parallel, over a temperature range from -20 C to +80 C. The conductance of the combined 2 k  $\Omega$  and required parallel resistance at 10 C intervals was plotted on the same scales as Fig. 3(a). Sliding the plot vertically across Fig. 3(a), and keeping the temperature scales coincident, gave the nearest suitable ratio of thermistor to shunt resistance.

Experience with these curves indicates that for most transistor work, the use of a resistor in series with the thermistor is not desirable. Its effect would be to flatten the conductance vs. temperature curves at the upper temperature limits. This fact should be kept in mind for any application which may require a modification of this type.

For a free reprint of this article turn to Reader-Service card and circle 389.

**Fig. 6.** Two values of  $I_{co}$  are used (Example 2) representing upper and lower limits of production spread as the boundaries of the shaded a rea. A point of perfect match is selected to minimize the error at the upper temperature limit. On the left is shown part of the log scale of Fig. 3(b) which was used in assessing the magnitude of the matching error.

## YOU CAN'T HEAR A 'SPEC' SHEET!

Sonotone's stereo cartridge has more than just good specs...it gives brilliant performance! More phono makers specify Sonotone for the top of their line-here's why:

Only Sonotone gives true sound without distortion...high frequency response without record cutting! Sonotone stereo gives a performance so superior you can truly hear the difference. The secret? Sonotone's four exclusive operating features:

- 1. Extremely high compliance.
- 2. Amazingly clean wide range frequency response.
- 3. Wide channel separation, due to Sonotone's pantagraph voke.
- 4. Rumble filter to screen out vertical turntable noise.

#### How To Use

## Pulsactors, Thyractors and Transactors

Harry E. Thomas

Federal Telecommunication Labs
A Division of IT&T
Nutley, N.J.

Pulsactors, thyractors, and transactors are gaining widespread use in pulse magnetics. A pulsactor is another name for a thyractor, which derives its name from "thyratron" and "reactor" for it combines properties of both. The transactor is a transformer, formed by adding another signal carrying winding to a pulsactor.

These devices are efficient and very reliable in pulse generators, multiplex circuits, radar modulators, and computers. They are simple. They are small. They have no moving parts and require no power supply. And they are available to handle milliwatts to megawatts.

Harry Thomas's wide experience seems to have shaped him for his present specialty—the design of magnetic components and allied equipment. His previous experience included design of deflection components and TV studio equipment, and prior to that, receiver circuits.

THE PULSACTOR is a special type of saturable reactor—not quite like conventional ones. It may look like a transformer or toroid winding, and may have a similar schematic symbol, as shown in Fig. 1, but it's different.

In conventional saturable reactors, impedance changes are controlled by dc currents in a separate winding, and are used to vary currents in series connected loads. The pulsactor, on the other hand, provides a triple molded action during each cycle of operation.

#### **How The Pulsactor Works**

The pulsactor starts as a variable low frequency reactor. Then it becomes a switch. Finally it becomes a very small inductance in a high frequency resonant circuit.

This three moded type of operation can best be visualized with the equivalent switch diagrams in Fig. 2. Here, the pulsactor's low frequency (unsaturated) inductance is called  $L_u$ , its high frequency (saturated) inductance  $L_s$ , and its switching from  $L_u$  to  $L_s$  is pictured by single or double pole switches.

Fig. 2A pictures the pulsactor becoming a two-

pole single-throw switch with series inductance in each of the switch blades. In the switch position shown,  $L_u$  operates normally as a high inductance. With the switch thrown to the left, the circuit inductance between terminals I and 2 becomes  $L_s$ , which is much smaller than  $L_u$ .

Fig. 2B shows  $L_s$  as an inductive switch. With the blades closed,  $L_u$  produces negligible shunting across  $L_s$  because it is so large a parallel inductance.

Fig. 3 shows the action in a simple pulsactor circuit. Sine waves excite an input resonant circuit consisting of  $L_0$  and  $C_1$  to a peak voltage.  $L_0$  is a linear charging reactor, followed by pulsactor  $L_{u1}$  which, when unsaturated, does not load the input tuned circuit.

ELEC

At the point of peak voltage across  $C_1$ , the pulsactor becomes saturated and discharges the capacitor to produce a steep-sided voltage pulse. If  $C_2$  were replaced with a pure resistance, the voltage waveforms would continue with positive and negative charging and switching excursions as shown in Fig. 3C.

But the switching action shocks a tuned circuit into oscillation. This tuned circuit consists of pulsactor  $L_{s1}$  (now in its saturated state) and the equivalent series capacitance of  $C_1$  and  $C_2$  which are connected across it. After switching, the pulsactor becomes a very small inductance. It resonates with  $C_1$  and  $C_2$  at a frequency much higher than the frequency of the input sine wave.

The unsaturated inductance may be 1000 times the saturated inductance, so the ringing frequency may be 30 times the initial sine wave resonant frequency of  $L_0$  and  $C_1$ .

PULSACTOR OR THYRACTOR

**Fig. 1.** Schematic symbols for the pulsactor (thyractor) and the transactor.

Fig. 2. Pulsactor equivalent circuits. A—as a DPST switch; B—as an SPST switch.

e 2

h

or

ıs

d Z<sub>2</sub> g, e. The circuit would continue to ring as shown in the dotted waveforms in Fig. 3E but its first positive excursion applies a sine wave across  $L_{u2}$ . This ringing voltage in turn, actuates a resonant circuit consisting of  $L_{u2}$  and  $C_2$ .

As the voltage rises across  $C_2$ , and  $L_{u2}$  becomes saturated, another discharge cycle takes place in cascade with the first, so  $C_2$  is discharged into R by the switching action of the second pulsactor in its unsaturated conditions. The waveforms at Fig. 3E show the increased steepness of this pulse compared with the one after the first stage.

These oscillations (dotted) would continue at a higher frequency than in the first part of the circuit if they were not damped by the load resistance. The output pulse across  $R_L$  is shown in Fig. 3F. It occurs later than the input sine wave and the first switching excursion. Since the coils associated with the initial resonance and with the first switching have returned to their unsaturated states, their effect on later circuits and their voltage pulses cannot pass through to the output.

Similar switching cycles can be repeated in successive pulsactor stages, the last of which can be made to deliver high amplitude, very narrow pulses. This compression is accomplished with constant voltage across the charging capacitors  $C_1$  and  $C_2$  and with increasingly narrow and higher amplitude pulses.

This current pulse compression ratio may be as high as 10 to 20 in a single stage. Thus, starting with a 2000 cycle sine wave, one half wave of which is 250 microseconds long, one may develop a 25 µsec excursion after the first switching cycle, a 2.5 µsec pulse after the second, and a 25 µsec pulse at the output.

provide Low Temperature Coefficient of Resistance

NEW

MOLDED

WIRE-WOUND

WIKE-WOOK

**POWER** 

TYPE

BULLETIN

153

Ohmite Molded Precision Power Resistors are exceptionally high-quality units providing excellent performance. They are wound in a single layer on ceramic cores. Temperature coefficient of resistance is low,  $0\pm20$  ppm/°C. Tough, molded, silicone-ceramic covering—abrasion and moisture-resistant. Insulated units with high dielectric strength. Wide selection of resistance tolerances: 0.1%, 0.25%, 0.5%, 1.0%, and 3.0%. Uniform size—ideal for automated assembly. Designed to meet MIL-R-26C. Maximum resistance: 3-watt, 10,000 ohms; 5-watt, 25,000 ohms; 10-watt, 50,000 ohms.

NEW

METAL-FILM

TYPE

BULLETIN

155

Ohmite RITEOHM® Metal Film Resistors feature full  $\frac{1}{4}$ -watt rating at 150°C ambient. These new units may be used at *full rated wattage* in higher ambients than other types of precision film resistors. Rated at  $\frac{1}{2}$  watt at 125°C. Excellent high-frequency characteristics; standard temperature coefficient is  $0 \pm 25$  ppm/°C over a wide temperature range of -55°C to +190°C. A T.C. of  $0 \pm 50$  ppm/°C is also available at lower cost; long term load and shelf stability. Resistance range: two sizes provide over-all range of 25 ohms to 350K ohms. The smaller unit provides resistances from 25 ohms through 150K ohms; larger unit covers the range over 150K through 350K ohms.

**Fig. 3.** Simplified pulsactor operation.

#### Circuit Details

There are many other circuit applications and practical details surrounding the operation. The most important of these use polarizing fields to restrict the switching action in each stage to a single polarity. In Fig. 3 for example, a dc polarizing current can be sent through a separate winding on the main coil of  $L_{u1}$ . This would restrict the voltage swings in the negative direction to leave relatively unidirectional output pulses, as shown in Fig. 3D. The circuits can be arranged so switching takes place at the peak of applied voltage swings.

#### **Switching Characteristics**

The pulsactor's inductance goes through a tremendous change due to the rapid change in slope of its B-H curve. Its permeability ( $\mu$ ) expressed as the slope  $\Delta B/\Delta H$  is extremely high compared with that of ordinary transformer iron. This can be seen in Fig. 4.

The transition from unsaturated to saturated conditions is much faster for pulsactor steel (point C to D) than for ordinary transformer

1958

The ratio of the steepness of the unsaturated part of the dotted curve in a typical high permeability iron compared with its flatness in the saturated region may be as high as 2000:1 com-

These high permeabilities make for better pulse performance and lower heating losses. Better pulse performance results from the fact that with high unsaturated inductance, the pulsactor oil may be kept small. At the same time the igh frequency range of a coil is extended since has fewer turns.

The lowered heating losses are a result of the arrow, steep-sided hysteresis curve. The small area of the loop indicates that the core generates ess heat in high frequency applications. These losses are further reduced by using very thin laminations and forming the iron into very thin tape wound cores.

Many complex metal treating processes and a vast array of alloys are required to produce these high permeability irons.

# SEMICONDUCTOR PLUS MICROWAVE COMPETENCE

Since 1952, Microwave Associates, Inc., has demonstrated a unique and effective effort combining solid state devices and microwave techniques. We have been the leader in the design and production of very low noise, reliable microwave mixer and video diodes to the extent that our silicon products are essential elements in almost all high performance microwave systems in use today.

For your future use, programs are now in progress which will soon make available diffused junction mesa silicon varactors for microwave amplification, detection, harmonic generation and low noise duplexing. If your microwave system planning will require a component involving sophisticated solid state and microwave techniques, why not avail yourself of our skilled team of physicists, metallurgists, and engineers now most active in this field.

## **New Digital System**

solves problems in a "TRICE"

ERE'S THE fastest digital differential equation computer in the world. It solves problems in real time. The basic pulse repetition is 3 mc. Word length is 30 bits. Iteration is 100,000/sec, regardless of problem length.

Stable sine waves up to 8000 cps have been generated by this computer, comparing with order-of-magnitude one cps for previous digital devices. In this way TRICE is the first digital computer to operate at analog speeds. And where analog computers may produce an output of 20 cps with one per cent accuracy, the new computer has an 0.1 per cent accuracy at its 8 kc. Reliable, too. As part of the checkout procedure  $e^x$  was run for two hours at  $10^5$  iterations per scc—and at the end of that time no error was discernible.

TRICE—the Transistorized Realtime Incremental Computer, Expandable—

Fig. 1. Interrelation of segments of hardware required to solve Van der Pol's equation. The equation,  $x'' + K(x^2 - 1)x' + x = 0$ ,  $dx' = -K(x^2 - 1)dx - xdt$ , represents a voltage loop in an oscillator circuit. The resistance term is  $K(x^2 - 1)$ . Energy in the loop is increased when the resistance is negative, decreased when it is positive. Each stable solution will form a loop. The equation has a stable oscillatory solution with the energy gains and losses cancelled for each value of K.

whe

#### How It Works

TRICE operates in parallel. This is how its great speed is possible. It is programmed by plugging independent computing elements into a board, like an analog computer. The size of the computer is dependent on the size of the equations to be solved.

An incremental computer, TRICE has as its basic element an integrator, which receives two incremental inputs,  $\Delta x$  and  $\Delta y$ . An incremental output that is an approximation of Ydx is generated. If the increments are summed, the result is a number.

#### $Z \approx \int Y dx$

over the number of  $\Delta x$ 's that have been used. Note that the independent variable can be any function, not necessarily *time*, a limitation of analog computers.

A simple form of integrator is shown in Fig. 2. A  $\Delta y$  is added to the first register to change the value of Y. When a  $\Delta x$  pulse comes in,  $Y\Delta x$  is added to R, which value becomes  $\Sigma Y dx$ .

Instead of accumulating this entire sum, the integral portion becomes a series of incremental outputs— $\Delta z$ —which can be used as a  $\Delta x$  or  $\Delta y$  input to other integrators.

To generate  $e^x$ ,  $\Delta z$  is fed right back in, as  $\Delta y$ . If the value in the Y register,  $e^x$ , is integrated with respect to X, the result is  $e^x dx$ , or  $d(e^x)$ . But of course this represents the increments which yield  $e^x$  when summed. So the answer is used as

the  $\Delta y$  of the integrator itself, closing the loop. If the Y value is started at some initial condition, the integrator will generate  $e^x$ .

#### **Computer Elements**

As mentioned above, the TRICE's basic element is an *integrator*. This unit consists of three recirculating 30-bit electrical delay line registers: Y, R and I. The I register stores initial conditions. Three adders are used to add y + x, y + R and to make the necessary trapezoidal correction. Output is stored in two flipflops that show the sign and existence of the output. If an overflow occurs, showing that the integrand has exceeded its preassigned full scale value, a light goes on and everything stops.

A digital servo generates an output whenever  $-1/2 \le Y < +1/2$ . Output sign is determined by the product of the signs of Y and X. It has six input lines and three outputs. An initial condition register is provided.

The variable multiplier needs five delay lines for X, Y, R and the two initial conditions; and four adders for summing  $X + \Delta x$ ,  $Y + \Delta y$ , X + R and Y + R.

A clock generator with a crystal-controlled 3 mc frequency, a timing counter, control flipflops and an overflow detector are packaged together as the control unit. Constant multipliers and  $\Delta y$  summers are also included as TRICE plug-in units.

The integrator package measures 12-1/4 x 1-3/4 x 20 in. Forty packages and their power supplies will fit in a 6 ft 19 in. relay rack. There are 110 transistors and 400 diodes in each integrator; 10 w are consumed. Thirty bits are stored in each line by a standard delay cable.

Dimensions for the digital servo are the same as for the integrator. However, it uses only seventy-five per cent as many components.

For further information on this digital differential-equation computer, turn to the Reader-Service card and circle 101.

## Fluorochemical Cooling

An ELECTRONIC DESIGN interview with

L. K. Kilham, Jr., Ralph R. Ursch, J. Francis Ahearn

Raytheon Mfg. Co. Waltham, Mass.

Until now, satisfactory reduction in transformer size could not be achieved because of limitations in conventional cooling liquids. Fluorochemicals, because of their thermal stability and good dielectric properties, have led to considerable reductions in size. Considerations in utilizing fluorochemicals for this purpose are discussed in this article.

#### ABOUT THE AUTHORS:

R. R. Ursch (left) attended Washington University, St. Louis, from 1946 to 1949, where he received his B.S. in Electrical Engineering. Since 1951 he has been with Raytheon at Waltham, Mass., where he has been engaged in engineering design and development of magnetic components.

J. F. Ahearn (center) has a long and productive career as a physical chemist. In 1953 he joined Raytheon as a physical chemist in the design and development of magnetic components. Mr. Ahearn's papers and lectures on heat transfer have won him recognition as an authority in this field.

L. F. Kilham, Jr. (right) graduated from Tufts University in 1939 with a B.S.E.E. Since 1942 he has

been employed by Submarine Signal Co. of Boston and by its successor, Raytheon. Mr. Kilham has been Chief Engineer of Magnetic Components since 1949.

#### How do the fluorochemicals compare with conventional cooling liquids?

Transformer oil, silicone oil, and fluorochemicals have all been proved compatible with materials commonly used in the manufacture of transformers. One of the outstanding characteristics of fluorochemical liquids is their ability to transfer heat from a solid surface. They are approximately twice as efficient as transformer oils in natural convection, (Fig. 1). Also, the heat transfer coefficient of boiling fluorochemicals is about ten times as great as the liquid or twenty times as great as the transformer oils in natural

cooling techniques.

Fluorochemicals also have a property of selfhealing after arc-over. Other transformer oils do not.

At one atmosphere, conventional oils and the fluorochemical vapors have equal dielectric strength. This means that it is not necessary to completely immerse a transformer coil in a fluorochemical liquid. If the liquid boils, the portion of the unit exposed to the vapor is protected against dielectric breakdown to the same extent as one completely under the liquid.

The plot of temperature gradient versus transformer losses, (Fig. 2), illustrates a comparison of cooling capabilities of various transformer coolants. Silicone oil, for instance, has a very high temperature gradient. For the same losses incurred in a transformer, transformer oil has a lower temperature gradient, and the transformer will operate at a lower temperature.

comp

resing

ELEC

#### How do they compare electrically?

Perfluoro compounds compare favorably with the silicone oil and transformer oil.

The dielectric constants, for instance, are about 1.90 for the fluorocoolants. The conventional coolants have a dielectric constant of about 2.5. Power factors at 100 cps range about 0.0025 to 0.016 for perfluoro compounds. Transformer oils have power factors of about 0.012 at the same frequency. Resistivities, in ohms per cm³, are approximately 6.3 x 10<sup>14</sup> for fluorocoolants and conventional oils. Both perfluoro compounds have dielectric strengths of 40 kv. Conventional oils have dielectric strengths of 30 kv.

#### Would you explain how a coolant is decided?

Fluorochemical dielectric materials range in boiling point from -78 to 177 C. The selected

HEAT TRANSFER COEFFICIENT W/IN2/DEG. C

Fig. 1. Heat-transfer coefficient obtainable with various cooling fluids.

Fig. 2. Comparison of coil-temperature rise above the container temperature with various dielectric liquids.

coolant depends on the requirements of the system. Ordinarily it is necessary to use a combination of low boiling materials and high boiling materials. The low boiling coolant insures protection at low temperatures. The high boiling perfluoro compound is employed for effective heat transfer. Operating ranges from -50 to 200 C have been achieved to meet certain military specifications. Combining a gas and a liquid has the advantage of saving weight while still providing dielectric protection and heat trans-

th

al 5.

to

ils

ne

d ds

Besides liquid and gas combinations there are wo other categories of cooling employed which should be mentioned.

The first method is the use of a complete gas cell. This method is applicable where thermal problems are not encountered and the voltage does not exceed 5 kv.

• Another method is a complete liquid fill. This system can be used where extremely high voltages are involved, 10 kv and up, and where high temperatures are reached.

#### Are there any special considerations taken in enclosing transformers that contain fluorochemial coolants?

Because of the presence of vapors, it becomes ecessary to make the containers as leaktight as possible. The materials, of course, must not react with the coolant. This is no problem, because huorochemicals are one of nature's most inert ompounds. They are compatible with silicone resins, varnishes, and other materials used for nsulation.

Since these transformers can operate in the 200 C region, low temperature solder must be avoided. High temperature solder and brazing techniques, which are impervious to gasses, must e utilized throughout the construction.

put transformer (left), reduced by about one-half in size and weight (right).

#### Are there any limitations in using fluorochemicals for magnetic component or transformer design?

There is one pronounced limitation. This is that generalization must be avoided. To achieve a substantial reduction in size and weight of a transformer, the problems involved must be treated individually and in their entirety. This means each new transformer must have both its dielectric and its mechanical problem solved. The mechanical problem includes heat transfer with such aspects as the heat sink, which is the mechanism to help remove heat. If the heat sink is designed for optimum heat transfer, the magnetic component can be made for maximum miniaturization.

#### What are the conditions for best heat transfer?

The ultimate in heat transfer and the condition that permits maximum miniaturization is when the vapor, produced by the liquid near the core and the coil, condenses on the heat sinks and the walls of the transformer. The condensed liquid is then returned to the system. This technique is about 100 times as effective as natural circulation.

#### How do fluorochemical coolants effect reliability?

Utilization of these coolants increases the reliability of transformers in a number of ways.

- They are completely non-flammable so there is no danger of fire upon rupture as with the use of conventional hydrocarbon coolants.
- Fluorochemicals have excellent corona inhibiting properties. Coronas generated with these coolants are considerably less than other high temperature coolants.

ple

rial

turi

was core faile

unit

Vap

wer

shie FC

one

ele

• Fluorochemical coolants effectively reduce internal radiance in the components, which reduces the maximum operating temperature. Since equipment life is limited by its operating temperature, a reduction in the temperature increases the life and reliability.

Fig. 4. Construction details show reduction of standard transformer (left) to one-quarter size (right).

ELECTRONIC DESIGN • September 17, 1958

The Penetration properties of fluorocoolants also increase reliability. Because of their capillary action properties, the fluorocoolants may rise as much as four or five inches against gravity. This permits wetting of nearly all the voids in the coil and core.

#### What precautions must be taken in handling these coolants?

. Since

ng tem-

ture in

vays.

Because the cost of these coolants can become ominous, the first precaution is not to use more than a design demands.

Fluorochemicals are very volatile and must be kept in closed containers. The chemicals are non-toxic, non-flammable, inert, and will not absorb moisture; therefore, they present no problems from these standpoints.

Fluorochemicals will be non-corrosive to metals if the system is dry. The equipment should be thoroughly dried before filling and filled preferably under a vacuum.

# What is the relative cost of fluorocoolants as compared to conventional oils for cooling transformers?

No generalization can be made on this point. Under certain conditions, the cost of fluorocooling is less than that of a conventional method. For instance, a case where vapors are completely utilized, the cost can be as low as \$3.00 per gallon. Silicone oil costs \$28.00 per gallon. If on the other hand, the transformer were completely filled with a liquid fluorocoolant, its cost would greatly exceed that of conventional materials.

# Would you give some examples where transformers using conventional coolants were miniaturized or improved by the use of fluorocoolants?

One specific example that comes to mind with respect to this was an epoxy unit which operated at relatively high voltage. Because the design was pressed for extreme miniaturization the corona level was high. This contributed to field failures. The problem was: How can a reliable unit be made in the same amount of space? Vaporative cooling fluorochemical techniques were applied. Because of their corona inhibiting properties, the transformer was made more reliable and still maintained its miniature size. Examples of reduction in size are:

■ A standard output transformer was reduced to better than one-half in size and from 20-7/8 lb to 15-1/2 lb. This was performed through the use of a combination of heat-conducting copper shields and tabs with a liquid fill of FC43 and

FC75, (Fig. 3).

Another transformer was reduced to about one-quarter size through the combined low dielectric constant and good dielectric strength of fluorochemical FC43, (Fig. 4).

NOW...sealed dependability in an adjustable, rugged, environment-free

Model H11-2 (Conforms to MS-24331)

- Use for any exposed control or indicating application on aircraft or machines.
- Corrosion resistant Stainless Steel or Monel used for all exposed metal parts.
- Heliarc welded for positive sealing and added strength.
- Meets all requirements of Immersion Test MIL-E-5272, Procedure 1.
- Header is brazed (not soldered)
- Mount anywhere through one mounting hole. Infinitely adjustable within %"—wire locking.
- Multi-Circuit Control.
   6 separate terminals permit many circuit combinations.
- High operating and overtravel force provides positive icebreaking characteristics to assure perfect, dependable operation.
- Light and Compact . . . yet rugged and impervious to all environment conditions.

# Variable Speed Tape Drive Works without Capstan

HERE IS A tape mechanism that can search through a reel of tape faster than most computers can digest information. It allows a computer to locate information blocks at any speed, and includes high-speed search at 920 in. per sec (ips). Read and write speeds of 30 to 100 ips are reached in 1/2 to 1-1/2 sec.

But most interesting are the design features of this tape system:

- The transport does not use a constant speed capstan. Two conventional three-phase motors pull the tape in either direction.
- The control system varies the speed by modifying the torque on driving motors after comparing the timing track bit rate with the desired bit rate. By this means, the computer can select an appropriate speed for recording data in real-time over prolonged periods.
- A separate channel of block marks enables the computer to locate information at variable speeds.
- A permanent, constant-density timing track on the tape provides the speed reference for the control circuits. This makes possible fixed position addressing and a variable rate of information transfer.

The tape transports were developed at Lincoln Laboratory, MIT, by R. L. Best and T. C. Stockebrand. It was designed for use with the TX-2 computer, which has a core memory of 2.5 million bits.

#### How It's Designed

The tape transports used in this system are as simple and fool-proof as possible. They consist of a read-write head assembly, two reels, two drive motors, and a tape guide. The drive mechanism has no capstan. A good deal of

mechanical complexity is therefore eliminated, which makes possible a wide range of tape speeds. Fast starts and stops are precluded, however: 1/2 sec and 7-1/2 in. of tape are required to reach 30 ips.

The figure shows the transport mechanism. The motors are flange mounted. Typical three-phase induction motors, they are rated at 1800 rpm, 1/8 hp, and have roughly constant torque characteristics when operating well below syn-

chronous speed. The hp rating, and therefore the torque, is as high as possible, limited by the tensile strength of the tape. These motors, each driven by a magnetic amplifier, provide the proper torque to operate 10 in. reels mounted directly on the motor shaft. The reels are loaded with polyester tape, 0.001 in. thick and 0.5 in. wide.

rec

ple

ter

is

wh

The head assembly and guide are shown in the insert of the figure. The large, constant

Tape Transport Mechanism

radius of the guide reduces the pressure between tape and guide. At speeds above 20 ips the tape floats on an air cushion and is easy to edge guide. Skew, caused by non-uniform tape tension across the width of the tape and by variations in tape width, is minimized. There is no wrap around the head. Variations in tape tension (which are large in this transport) do not, therefore, cause excessive pressures on the head and wear is reduced. Because only short wave lengths (0.0025 and 0.005 in.) are used in the system, the area of tape-head contact need not be large.

The direction in which the transport is moving is determined by a sensing device mounted on the rear shaft extension of one motor. The sensor consists of an iron cup dragged against one of a pair of stops by hysteresis from a star shaped permanent magnet on the motor shaft. The cup operates a mercury switch by rotating an attached magnet. This scheme gives positive direction information even at the slowest tape speed. A mercury wetted contact switch provides computer-level signals to the control without contact bounce and with good reliability.

#### **How Tape Speed Is Controlled**

Each motor can generate torque in only one direction to pull the tape from one reel to the other. The control of the motors is therefore simpler than if torque had to be reversed. Since tension is limited by tape strength, acceleration is relatively slow. A sudden change of torque, which might allow a loop to form, is prevented by a long time constant in the control windings of the motor magnetic amplifier.

To stop the tape, full torque is first applied by the trailing motor until the tape speed falls below 20 ips. At that point dc applied to the trailing motor, brings the tape to a smooth stop. The direction sensor indicates which motor is trailing. With dc in the motor field winding the rotor will resist applied torque even at zero velocity due to the hysteresis in the rotor. Voltage is never completely removed from either motor. Some tape tension is always maintained. The end of the tape is sensed by a photoelectric call which receives light through transparent leaders at each end of the tape. The timing track is continued on the edges of the 100-ft transparent strips. This lets the control element know when the tape has fallen below 20 ips.

Feedback is included to provide close control of minimum torque. Too much minimum torque fails to overcome static friction, and doesn't allow a loop of tape to form. The feedback prevents large variations in the output current of the magnetic amplifier which would be caused by unbalanced line voltage or small variations in reactor control current. This is especially true when the amplifiers are cut off.

Model 424 as a closed loop system—Model 424R with supply and take-up reels. Detailed information and complete specifications are contained in Bulletin H-424, available upon request.

THE NEW

PE TRANSPORT ANALOG OR DIGITAL

**DESIGN FEATURES:** 

pletely independent capstans and storage baskets. h speed (2 ms) start-stop. No resonance or reel jitat any cycling rate to 150/second.

Simultaneous record and reproduce at different speeds if desired.

- Either station can operate as closed loop or conventional reel transport.
- Speeds from 7½ to 60 ips either station (higher and lower on special order).
- Each storage bin adequate for more than 250 feet of
- Head to head spacing (Station 1 to Station 2) less than 4 inches.
- Automatic (on command) transfer of message start from Station 1 to Station 2.
- Very low flutter and wow.
- Tape tension controlled by unique vacuum pressure
- Tape widths from 1/4" to 1" (up to 2" on special order).
- Completely transistorized.
- Modular construction.
- Low power demand.

## Airborne Electronic Transformers

G. R. Carl

R. A. O'Connor

General Electric Co.
Specialty Transformer Dept.
Fort Wayne, Ind.

Fig. 1. Logarithmic plot of operating temperature and life of insulation system.

Fig. 3. Altitude plotted against spacing ratio.

Fig. 2. Altitude plotted against per cent increase in temperature rise for two different ambients.

Aside from the usual parameters associated with general transformer design—frequency range, regulation, duty cycle, capacity, etc.—two additional considerations are necessary when designing transformers for airborne applications. The authors offer a terse and lucid definition of these additional parameters which should prove helpful in the design of highly reliable airborne transformers with higher operating temperature and life ratings.

T WO DESIGN parameters, not normally associated with ground based applications, must be considered when determining the size and weight of encapsulated transformers for airborne applications. These parameters are:

■ Life expectancy rating

Maximum altitude rating.

By clearly defining these ratings, the circuit designer can obtain a transformer having the proper balance between reliability and minimum size and weight.

#### Life Expectancy

Recognition of life ratings has proved extremely beneficial in reducing size and weight of airborne transformers. Manufacturers are able to take advantage of the fact that the logarithm of life of an insulation system is approximately an inverse function of the operating temperature of the system (Fig. 1).

Thus, depending on the minimum life required, a single transformer insulation system may be qualified at various operating temperatures. Actual savings depend on both the maxi-

mum ambient temperature and the allowable ultimate temperature. Since military specifications call out two classes of transformers having 105 C and 30 C maximum ultimate temperature, a transformer rated for a 95 C maximum ambient has much more to gain by having its ultimate operating temperature increased from 105 C to 130 C (250 per cent increase in allowable temperature rise) than a similar unit rated for a 65 C maximum ambient (62 per cent increase in allowable temperature rise).

No exact relationship has been established for encapsulated transformer size reduction resulting from various percentage increases in allowable temperature rise. However, it is estimated that doubling the temperature rise will reduce the size by approximately one-third.

#### Maximum Altitude

While short life expectancy ratings tend to decrease the size and weight of airborne transformers, maximum altitude ratings have an opposite effect. As altitude is increased the radiation and convection coefficients for heat transfer from the transformer to the ambient air are adversely affected. A transformer designed for a specified temperature rise at sea level conditions will have a higher temperature rise when operated at increased altitudes (Fig. 2).

Transformer life could be downgraded from any prolonged period of operation at the combined conditions of maximum altitude and maximum ambient temperature. In most instances such a condition will not exist since ambient temperature tends to decrease with increased altitude. The circuit designed should determine and specify the maximum ambient temperature that exists at maximum altitude. Transformer designers can then design optimum transformers based on realistic conditions rather than provide safety factors to insure reliable operation at conditions which may never exist.

Altitude will also affect dielectric breakdown. As air density decreases, its dielectric strength also decreases. Transformers must be designed to provide sufficient spacing between terminals and between terminals and ground to prevent arc-overs or flash-overs under the conditions of maximum altitude and maximum working voltage.

The designed spacing must allow for a reasonable decrease in spacing resulting from the equipment manufacturer's lead connections. An indication of required increases in spacing due to altitude is shown in Fig. 3. At times the combination of working voltage and altitude requirements becomes the limiting feature of a transformer design. In these cases the required spacing rather than the volt-ampere rating determines the size of the unit.

#### FOR UNVARYING PERFORMANCE

PRECIOUS METAL CONTACTS... for long operating life and unvarying performance. Available in pure or alloyed forms of Silver, Platinum, Palladium, and Gold. These contacts provide extremely high resistance to atmospheric corrosion, deformation, arc erosion, sticking and metal transfer. They are supplied as wire, rod, sheet, and as fabricated forms.

Baker Contact Division, 207 Grant Avenue, East Newark, Harrison P. O., N. J.

WRITE TODAY FOR BULLETIN G-180 INCLUDING COMPLETE MECHANICAL AND ELECTRICAL SPECIFICATIONS, DIMENSIONAL DRAWINGS GRAPHS AND ENGINEERING

General Transistor's new 2N602, 2N603, 2N604 provide the design engineer with guaranteed switching parameters such as gain-bandwidth and DC current gain, while the 2N605, 2N606, 2N607 and 2N608 provide guaranteed power gains at high frequencies. In addition to the great speed advantages offered by the drift transistor at no sacrifice of gain,

such additional features as higher voltages and lower capacity are available. Thus one can now drive higher impedance loads with no sacrifice of speed or pulse power.

The complete control of G. T.'s Drift Transistor assures longer life and maximum performance while possessing complete reliability.

Other features include: high input-circuit efficiency, excellent high-frequency operating stability, good signal-to-noise ratio, good automatic-gain-control capabilities and the rugged mechanical construction of a positive hermetically sealed JETEC 30 case.

ALL TRANSISTORS CAN NOW BE SUPPLIED IN FULL COMPLIANCE WITH MIL-T-19500A.

# Power Dissipation Class B Circuitry

C. Frank Wheatley Semiconductor and Materials Div. Radio Corporation of America Somerville, N.J.

In a discussion of complementary symmetry audio amplifiers (ED, Aug. 6), the author showed how this principle can be applied to the design of a Class B system. This article analyzes in greater detail transistor dissipation in Class B operation.

WHEN A power amplifier is designed or tested, the most severe operating condition for the output stage is often considered to be "full drive." Under some abnormal conditions this assumption is true. With regard to dissipation, however, the assumption is erroneous.

The fallacy is obvious for a class A output stage because the output subtracts from the fixed power supplied, thereby reducing dissipation as the power output increases. For class B operation, however, the actual condition is not nearly so obvious.

Fig. 1. In this basic circuit, assume ideal transformers and linear transistors.

Fig. 2. How dissipation for each transistor varies with power output.

This article shows that the dissipation in a class B stage operating at 10 per cent of rated power output is greater than that at full power output (sine-wave excitation). The maximum dissipation occurs at approximately 40 per cent of rated power output.

1958

For purposes of discussion, transistors are referred to as the output devices. However, the analysis applies equally well to electron tubes. In practice, transistors approach the assumption of zero saturation voltage more closely than electron tubes (relatively speaking) and, therefore, will agree more closely with the theory.

In the circuit of Fig. 1, it is assumed that the quiescent current of the transistors is zero and that the saturation voltage of the transistors is zero. Ideal transformers are also assumed, as well as linear transistors.

The collector voltage on a given transistor is given by:

$$v_c = V_{ec} (1 - A \sin \omega t) \tag{1}$$

The collector current is given by:

$$i_c = \frac{V_{cc} A}{R_L} \sin \omega t \text{ from 0 to } \pi \qquad (2)$$

$$i_c = 0 \text{ from } \pi \text{ to } 2 \pi \tag{3}$$

Dissipation for each transistor, therefore, is:

$$P_{c} = \frac{1}{2\pi} \int_{0}^{\pi} (V_{ec}) (1 - a \sin \omega t)$$

$$\frac{(V_{cc} A)}{R_{L}} (\sin \omega t) d\omega t \quad (4)$$

$$=\frac{V_{cc}^2 A}{\pi R_L} \left[ 1 - \frac{A \pi}{4} \right] \tag{5}$$

The max dissipation can be determined as a function of A from the following relation:

$$\frac{dP_c}{dA} = \frac{V_{cc}^2}{\pi R_L} - \frac{V_{cc}^2 A}{2 R_L} = 0 \tag{6}$$

Max dissipation occurs when:

$$A = \frac{2}{\pi} = 0.636 \tag{7}$$

The max dissipation, therefore, is given by:

$$Pc_{max} = \frac{V_{cc}^2}{\pi^2 R_L} \tag{8}$$

which may be normalized with respect to the theoretical max power output:

$$\left(P_0 = \frac{V_{cc}^2}{2 R_L}\right)$$
, as follows: (9)

$$P_{c_{max}} = \frac{2P_0}{\pi_2} = 0.203 \ P_0 \cong \frac{P_0}{5}$$
 (10)

The dissipation of a transistor as a function of power output is shown in Fig. 2. The power-output scale is plotted in per cent of

$$\frac{V_{cc}^2}{2 R_L}.$$

When a quiescent current flows, it may be shown that the max collector dissipation is given by:

$$P_{c_{max}} \le \frac{2P_0}{\pi^2} + V_{ee} I_0$$
 (11)

The efficiency of the output pair may be determined to equal:

$$\eta = \frac{\pi A}{4} \tag{12}$$

set to make pots!

If you're a fanatic about resolution, you could wind your own pots! Of course, it is a bit of a nuisance having to design and build those special winding machines able to deliver 0.1% linearity. Just dream up some fancy controls to keep the windings and spacing within microscopic tolerances, and you might make it!

But if you want to save all that fuss, just come to Ace. We've already designed and developed our own special winding machines, and they're all running nicely, turning out the kind of close linearity and high resolution through winding and spacing accuracy that only these machines . . . and Ace know-how . . . can produce. So don't build-it-yourself! For pots with the accuracy that pays off in performance.

Here's highest resolution in a standard sub-miniature pot: The Series 500 Acepot<sup>®</sup>. Single-turn, 1/2" size, from -55°C to 125°C. ±2% resistance tolerance, 0.3% independent linearity. Special prototype section insures prompt delivery.

#### **BACKGROUND FOR DESIGNERS**

Fig. 1. Four styles of parabolic reflectors.

All energy emitted from a point source at the focus of a parabola will be reflected from the surface in rays parallel to the axis of the parabola. This characteristic makes the parabolic reflector especially useful in long-range high-frequency communication. Some basic design considerations necessary to achieve this result are presented in this article.

#### Elements of design of . . .

## Parabolic Reflectors

Arthur S. Kramer

Allen B. Du Mont Laboratories, Inc. Clifton, N.J.

Art Kramer is the Engineering Analyst of the Research Administration Department at Du Mont. He is primarily responsible for the coordination of the estimating and pricing of all the R & D proposals which require this service. Art received his BS in EE from Brooklyn Polytechnic Institute and has been with Press Wireless Co., Crosby Laboratories, Curtiss-Wright and Air Associates. While at Du Mont he has specialized in the design of horn antennas and parabolic reflectors. He also assisted in the Forward Scatter project and was responsible for various measurement aspects of this system.

PROPERLY focused and energized parabolic reflectors are equivalent to a very large number of dipoles, all polarized in the same plane and energized in phase. Fink<sup>1</sup> refers to this effect as "current sheet of in-phase dipoles." And this effect gives the reflector its highly directional properties.

To assure good performance, these factors must be considered in design:

- Type
- Feed Methods
- Illumination
- Gain
- Radiation Pattern
- Mechanical Adjustments
- Reflector Material
- Manufacturing Tolerances

#### **Types of Parabolic Reflectors**

Parabolic reflectors come in several forms. Most common are the circular parabola, the orange peel parabola, the parabolic cylinder and the square or truncated parabola (Fig. 1). Characteristics of these various forms of paraboloid

are discussed by Reintjes and Coate.<sup>2</sup> Most attention will be given here to the circular paraboloid or "parabola of revolution."

#### Methods of Feeding

Feed methods for parabolic reflectors can be divided into two general classes: (1) rear feeds, and (2) front feeds. Of the various rear feeds, the half-wave dipole and the "Cutler" ring-focus feed are the most commonly used. Front feeds are usually accomplished by using some form of electromagnetic horn. These horns are usually either rectangular or of the square "diplexer" type in shape. The aperture of regular front feed horns is so dimensioned that a certain "taper" of illumination across the face of the parabolic reflector is achieved. Magnitude of this "taper" has an important effect on the radiation pattern of the dish.

#### Illumination

Besides a smoothly tapered illumination, several other illuminations are of interest, even though some of them are unobtainable. Uniform

illumination, of course, gives not only maximum gain and minimum main-lobe beam width, but also maximum side-lobes. Reintjes and Coate<sup>2</sup> have calculated curves showing beam width and side-lobe suppression for several illuminations. Another interesting method<sup>4</sup> is called "Illumination in Accordance with Binomial Coefficients." No side-lobes whatsoever occur.

(ha

pre the diu

hig I

par

ind

boi

tro

Most authorities agree that an illumination which is smoothly tapered from the center of the parabola to its rim, and which has an amplitude at the rim 10 to 15 db below that at the center will give a good compromise between gain, beam width, and side-lobe suppression. If a condition of "phase incoherence," (when the various components are not in phase across the dish diameter) exists in the illumination, changes will take place in major and minor lobes of the pattern.

#### Gain

Getting the maximum gain from any reflector is extremely important. Fig. 2 shows a power level chart for a typical tropospheric scatter propagation circuit.

A number of formulas and nomograms for quickly calculating the gain of a parabolic dish are given in the literature. Although they differ in details, it is clear that the area of the aperture is the governing factor for gain.

Gerks,<sup>5</sup> RCA,<sup>6</sup> and "Reference Data for Radio Engineers,7 all give equations for gain, the results of which differ only slightly.

The easiest method of measuring the gain of a parabolic dish in the field is by comparing its performance over a short unobstructed path with that of a "gain-standard" or reference horn, the gain of which has been carefully measured under ideal laboratory conditions.

#### **Radiation Pattern**

Two of the most important aspects of the radiation pattern of a parabolic dish are the 3 db (half-power) beam width and the side-lobe suppression. These two quantities jointly determine the width of the beam in the tropospheric medium, and the maximum bandwidth. Generally, the greater the beamwidth the greater the multipath effect, and the greater the multipath the more restricted is the bandwidth of the microwave circuit. For these reasons, every effort should be made to get narrow beam widths and high values of side-lobe suppression.

Richmond<sup>8</sup> has done some work on the techniques of calculating patterns of horn antennas, which function in a manner similar to that of a parabola, both being aperture type antennas. He indicates that far-field patterns can be calculated through the main lobe in less than one hour on a desk calculating machine. It is safe to say that calculating the full pattern would be a very laborious job. It can be done, however, if an electronic computer and the services of a trained mathematician are available.

#### **Mechanical Adjustments**

Several adjustments are available to the engineer so that a good compromise may be obtained

Fig. 2. Relative attenuation from transmitter to receiver.

**READ-OUT DOWN TO** .002 V. dc

Like having two VTVM's connected into a circuit for comparison readings - the 405 permits instantaneous switching between two inputs - either ac or dc without disturbing a single probe in the circuit. The same switch provides a Meter Zero position for convenient, fast calibration; again, without disturbing test probes.

And that's not all! The 405 offers full-scale sensitivity of 100 millivolts, dc or ac, resulting in accurate read-outs down to .002 volts dc, or .01 volts ac.

Add these outstanding features to the following, and you'll quickly discover why the 405 is today's best buy in a VTVM ...

between gain, beam width, and side-lobe suppression. One is illumination taper which can be varied by using front feed horns of different aperture dimensions until the best conditions are obtained. Another adjustment is the focal distance. It has been found that the best way to adjust the focal distance is to start out with the calculated value and vary it until the best compromise is found. Several different feed horns with different apertures can be tested and the best combination selected for permanent use.

#### Materials Used in Construction

Several methods of construction are available to the designer of parabolic reflectors:

- Solid sheet metal reflecting surface, assembled together as sectoral pieces.
- Metal foil over plywood base. Somewhat lighter and cheaper to fabricate than the solid sheet-metal type. But plywood has a tendency to warp, causing a gradual deterioration in the parabolic surface. Side-lobe suppression and beam width suffer. Found only in parabolas of about 10 ft and smaller. An excellent way of making small, low-gain, inexpensive dishes which are easy to mount and feed.
- Open-mesh construction. Reflecting surface may be made of thin sections of expanded metal or parallel bars assembled to give an equivalent parabolic surface. Open mesh construction has the advantages of: (1) low wind resistance; (2) low cost; (3) ease of fabrication and assembly; and (4) ability to conform to parabolic shape. But: (1) gain is reduced; (2) cross-talk may be increased; (3) intensity of side-lobes with respect to main lobe may be increased, and there may be

a loss in isolation between the two cross-polarized feeds of a diplexer-type feed horn.

Curves (Fig. 3) showing transmission through an expanded-metal reflecting surface for both planes of polarization and for four sizes of screen mesh have been evolved by Richards and Devane. Harris 10 claims that the open-grid or parallel-bar type of parabolic reflector is the equal gain-wise of a solid spun aluminum dish in the 6 and 10 ft sizes at 900 megacycles.

So far as can be determined, the relative resistivity of the reflecting surface has little or no effect on the gain and efficiency of a parabolic reflector. For this reason, at least from an electromagnetic standpoint, it is reasonable to believe that reflecting surfaces made from copper, untreated aluminum, anodized aluminum or stainless steel will perform equally satisfactorily.

An interesting recent development consists of an air-inflated fabric balloon with parabolic contour. One surface is coated with aluminum particles to reflect electromagnetic energy. A 30 ft dia model weighs only 1700 lbs as compared to 10,000 lbs for a conventional dish of the same size. The 30 foot model can be held to a tolerance of 1/16 inch over the entire surface. In use, the inflated dish is housed in a plastic radome.

#### Tolerances in Manufacture and Adjustment

Friis<sup>11</sup> claims that an error of  $\Delta$  in the reflecting surface of the parabolic reflector will result in an error of about  $2\Delta$  in the phase front. He recommends that the maximum tolerance to be allowed in the reflecting surface should be held to  $\pm \lambda/16$ . The primary feed should be placed as close as possible to the focal point of the dish. Defocussing will result in a circular curvature of the phase.

All Hughes diodes resemble each other—externally. Germanium point-contact or silicon junction, they are all glass-bodied and tiny (maximum dimensions: 0.265 by 0.107 inch). But minute, meticulously controlled variations in the manufacturing process impart individual characteristics to the diodes, make them just right for specific applications. This gives you the

opportunity of selecting from a line which includes literally hundreds of diode types.

So, when your circuitry requires varying combinations of such characteristics as... high back resistance...quick recovery... high conductance...or high temperature operation, specify Hughes. You will get a diode with mechanical and electrical stability built in. You will get a diode which

was manufactured first of all for reliability.

\*Nowhere else have glass packaging techniques been developed to a comparable extent, for the Hughes process has many unique aspects. They are difficult to duplicate, yet are instrumental to the manufacture of diode bodies which are completely impervious to contamination and moisture penetration.

tio

D ATA REQUIRED by the systems design engineer are in general the same as those needed by any design function plus a quantity of additional information which is generally considered as falling outside the technical domain. Considerable amount of coordination is, of course, necessary, inasmuch as a variety of items must be joined together to produce an operational ensemble. This joining process involves not only the hardware but also includes a meeting of the minds of all those concerned in the operation.

The various phases of system design—technical and economic—are blocked out in the diagram. Assuming that the parameters to be instrumented are physical, such as acceleration, pressure, temperature, it is first necessary to know what is to be measured; where it is to be measured; and when the data is to be utilized. Here at the very start, coordination enters the picture. This involves a series of meetings and conferences to establish priorities of time and importance, i.e., who needs what and which comes first.

The question of data requirements enters at this point. The resolution of such a situation may require weeks before a duly authorized instrumentation list is issued. This list may be subject to modification from time to time as the system design progresses. The items listed will spell out such things as the name of the parameter to be measured (coded as to system relationship), the excursion range of the parameter, the units in which it is designated, the accuracy desired, priority, etc. Once a reasonably firm instrumentation list has been established, the systems engineer probably has a pretty fair idea concerning the economic factors indicated on the chart.

With the instrumentation list in hand, the next question involves environment; where are the transducers to be located? Here again, if the system involves aircraft or a missile, the instrumentation list may call out a frame and a sector number. In any case, detailed information must be acquired as to the exact mounting point (if possible) and the method of attachment. The matter of fastening a

Time Schedule

Costs

Procurement

transducer to the structure of a thinskinned missile may become quite involved. It may be that a suitable transducer is not procurable. If such is the case, a development program may be instigated within the company, or bids may be requested from other concerns.

Assuming that suitable transducers are available, detailed data on accuracy, repeatability, linearity, hysteresis, etc., must be analyzed. This particular phase of design may develop into a highly involved process. There is a universal lack of uniformity in the definitions of terms. In one particular instance involving a million dollars or more worth of transducers, a vendor is said to have spent two hundred fifty thousand dollars on standardization adjustments before the situation was resolved. The controversy stemmed from differences in term defini-

Having selected a suitable transducer, arrangements must be made to present the data therefrom in a form most suitable for the purpose in mind. Quite often the readout must provide a quick look

as well as transmittal and storage. The quick look may involve a meter or a strip chart. Transmission may involve radio linkage if the pickup is moving, or simply a transmission line with suitable terminations, as in ground support installations. In both airborne and ground installations, magnetic tape and/or photographic film may be used for storage purposes.

The economic aspects of the problem may loom very large depending upon the time schedule and the urgency involved. If the program is on a crash basis, with no holds barred, costs can be ignored and procurement facilitated at least as far as purchasing is concerned.

Then again if the urgency is not quite so great, a target date, subject to revision may be established with specified limits on overtime, premium cost payments, etc.

Finally, the more normal approach is involved when a decision is made to develop a certain system with the schedule fitted into the programmed activities of a department.

From General Electric . . . PLAIN TALK ON TANTALYTIC\* CAPACITOR AVAILABILITY It's time for plain talk on the facts of tantalum electrolytic capacitor availability. There is no "availability" problem as far as General Electric is concerned. Here's why:

- No metal shortage-Stocks of capacitor-grade tantalum have doubled within the past year.
- No production capability shortage—General Electric's production facilities have tripled in the past year.
- No delivery bottlenecks-General Electric's improved manufacturing processes and techniques have virtually eliminated production rescheduling.
- Few military directive priorities—Since the supply of Tantalytic capacitors has met demand, the military requirements can be met without directive priorities.

This is why we say—now and in the future, General Electric will continue to provide Tantalytic capacitors in the types and ratings you want-when you want them.

For specific information on Tantalytic capacitor ratings, prices, deliveries, contact your nearest General Electric Apparatus Sales Office or write to General Electric Co., Section 449-4, Schenectady 5, N. Y.

## **DESIGN FORUM**

Unusual output circuitry, an ultrasonic carrier, and combined feedback, help make a very stable, efficient power supply

WHEN a power supply can provide zero, or even negative output impedance—that's unusual. In our July 1, 1957 issue, we described the performance of this supply, its excellent regulation, its negligible drift, and its fast response.

Now we want to describe how it works. Manufactured by Optimized Devices, Inc., of White Plains, N. Y., the power supply uses negative voltage and positive current feed-back, and a modulated ultrasonic carrier.

It's well known how output impedance can be reduced with negative feedback, as in Fig. 1, by increasing the feedback-gain product, in the expression  $Z_{out} = Z_{int}/(1-\beta K)$ . But  $\beta K$  would have to be infinite to provide zero output impedance and large  $\beta K$  values can introduce

Fig. 1. Basic arrangement for negative voltage feedback.

# Output Impedance-Zero

serious instability.

And that's where positive current feedback enters the picture. The output impedance in Fig. 2 is  $Z_{out} = R(1-K) + Z_{int}$ . With this scheme, R can be varied to make  $Z_{out}$  zero or negative.

The power supply block diagram of Fig. 3 and the schematic in Fig. 4 show how the combination feedback is used. This low voltage supply is a closed loop system with two main feedback paths.

The negative feedback is from the output, through R1 to the second grid of the differential input amplifier V1. This feedback helps reduce the output impedance and noise, and regulates the output voltage. The "Z<sub>o</sub>" control provides positive feedback to reduce the output imped-

ance further to zero or small negative values. " $Z_o$ " taps off the output driver where there is a square wave voltage proportional to the load current. The 0.1  $\mu$ fd capacitor across " $Z_o$ " averages the square wave to provide dc.

The coarse and fine controls deliver a reference voltage from an OB2 105 v VR tube, while the R2,3,4, combination supplies a line regulation compensating voltage.

The dual cathode bias arrangements in both V1 and V2, a second differential amplifier, help stabilize the output against the effects of filament voltage variations and tube aging.

V2 modulates V3, a free running multi-vibrator whose frequency varies inversely with load current from 20 to 50 kc. Thus, with light loads, this carrier frequency is high, resulting in very low ripple. The frequency drops with heavier loads, resulting in increased selenium rectifier efficiency.

V4 amplifies the ultrasonic carrier and drives the output tube. The unusual drive circuitry and power output circuitry (V5) make for a highly efficient power amplifier. It can deliver high power output with an 80 per cent theoretical plate efficiency. Yet V5 dissipates very little power when lightly driven. Its average bias as a switch is proportional to the driving signal, with the tube operated as a switch (either saturated or cut off). Hence no fixed or cathode bias.

For more information turn to the Reader-Service card and circle 100.

Fig. 4. This low voltage power supply uses negative voltage feedback, positive current feedback, line regulation, and a very unusual output stage. (Internal power supply not shown, uses traditional circuitry).

# **NEW PRODUCTS**

Covering all new products that might generally be specified by an electronics engineer engaged in the design of original equipment.

#### DC AMPLIFIER

A solid state chopper, consisting of a magnetostriction driven capacitor, is featured in the model 74 dc amplifier. The chopper provides  $\mu\nu$  per day stability. Chopper frequency is 8 kc, well outside the 1-kc bandwidth of the amplifier, and therefore chopper intermodulation is prevented. Input is differential, with infinite impedance to dc, and it is entirely isolated from ground. Either side of the floating output may be grounded. Common mode rejection is 100,000:1 for common mode signals of 100 v.

# WESTINGHOUSE TAKES A GIANT STEP IN SILICON POWER TRANSISTORS

Through major improvements in silicon purification and transistor fabrication, Westinghouse has broken down the previous limitations of Silicon Power Transistors. The result is a new series of Westinghouse Power Transistors which can operate at high efficiencies in the "true power range."

LIFE-SIZE DRAWING shows how Westinghouse Silicon Power Transistor is designed for attachment to heat sink with a screw stud. All leads are in the base.

	Some Track	10.168		personal subjects
*	CURRENT		VCE (VEB=0)	Rs
WX1015	2 AMPERES	30-300V	30-300V	0.5 OHMS TYPICAL
WX1016	5 AMPERES	30-300V	30-300V	0.4 OHMS TYPICAL

Thermal resistance—Junction to case, 0.7°C/watt typical. Current ratings based on the current at which current gain is equal to or greater than 10. It is possible to switch higher collector currents with some sacrifice in gain.

These are the first members of an entirely new family of Westinghouse Silicon Power Transistors, which have the advantages associated with silicon (high voltages and high operating temperature) without the disadvantages (high losses). As you can see from the chart below, these units possess exceptionally low saturation resistance—less than one half ohm. This low saturation resistance results in low internal dissipation. Coupled with high power handling capacity, it makes possible silicon transistors which can efficiently handle 1000 or 1500 watts. For example, as a DC switch, handling 1.5 kw (300 volts at 5 amperes) the internal dissipation of the units is about 12.5 watts with a resulting efficiency of better than 99%.

Like other silicon devices, these transistors can operate in ambient temperatures up to and exceeding 150°C while germanium units are limited to 85°C. Thus, where the higher power rating is not required these units may be used for their high temperature capabilities. It also follows that wherever germanium power units are presently employed, a switch to silicon transistors will result in higher reliability of operation, because of the greater margin of safety with respect to operating temperature.

There are a great many circuits for which this new type of silicon power transistor is made to order. It will

YOU CAN BE SURE ... IF IT'S

Westinghouse

find use in inverters or converters (AC to AC, AC to DC, DC to AC, DC to DC), to control frequencies for data processing, servo output, and other aircraft information applications. It will serve as a low frequency switch, as mentioned above; it will operate efficiently with low power supply voltages; and it will find a number of uses in class A amplifiers. There are also many additional applications—too numerous to list here.

These Westinghouse Silicon Power Transistors are available in sample quantities for your testing and immediate application. Call your Westinghouse representative or write directly to Westinghouse Electric Corporation, Semiconductor Dept., Youngwood, Penna,

LOW SATURATION RESISTANCE is exhibited in this graph showing values for a typical Westinghouse Silicon Power Transistor driven to 5 amperes. The values are fractions of those observed in other silicon transistors.

U. S. Air Force personnel remove 25,137 hour klystron from advanced Pole Yault base. Department of Defense Photograph.

#### **Eimac Klystrons Going Strong**

after 25,000 Hours in Pole Vault Tropo-Scatter Service

After 25,137 hours on the air, and still in perfect operating condition, this Eimac 3K50,000LF UHF klystron has been acquired through the cooperation of the U.S. Air Force and Canadian Marconi, Ltd. This klystron was one of the original tubes installed in Project Pole Vault, the first tropo-scatter communications line ever established. The tube is just one of a number of Eimac klystrons that have exceeded 25,000 hours of reliable on-the-air time in this system. Eimac klystrons are used as final amplifiers in the Pole Vault 10 kilowatt transmitters that handle multiple-channel voice and teletype communications. Experience with this first system in our early warning defense network confirmed klystron-powered tropospheric scatter as an outstandingly dependable system of long distance communication.

The exceptional performance of these tubes under the difficult logistical and environmental conditions of the far north is indicative of the reliability and conservative rating of performance-proved Eimac external-cavity klystrons. Eimac amplifier klystrons are now being used extensively for tropo-scatter communications throughout the United States, Canada and other regions of the world. Eimac klystrons for communications and pulse applications are now available covering frequencies from VHF to SHF and to multi-megawatt output powers.

For further information, write for a copy of the 24-page booklet "Klystron Facts Case Five."

# THE INCREDIBLE SHRINKING RESISTOR ...

Daven has always been the leader in the miniaturization of precision wire wound resistors. Now, due to further advances in resistor manufacture, Daven is able to offer higher resistance values in smaller sizes than ever before. Typical miniature units, with their new maximum values, are tabulated here.

For guided missiles, airborne radar, telemetering, and for any application where extremely small size

and dependability are of prime importance, specify Daven miniature wire wounds.

# THE SPRAGUE TRANSI-LYTIC\* FAMILY

of tiny electrolytic capacitors for every requirement in entertainment electronics . . . pocket radios, wireless microphones, miniature tape recorders, auto receivers

# LITTL-LYTIC\*

Sprague's new Type 30D hermetically-sealed aluminumencased capacitors are the tiniest electrolytic capacitors made to date . . . and their performance is better than ever. Their remarkable reliability is the result of a new manufacturing technique in which all the terminal connections are welded. No pressure joints . . . no "open circuits" with the passage of time. And check this for ultralow leakage current: for a 2 µf, 6 volt capacitor . . . only 1.0 μa max.; for a 300 µf, 6 volt capacitor ... 3.5 µa max.! Engineering Bulletin No. 3110 gives the complete story. 85°C standard.

\*Trademark

POR ENGINEERING BULLETINS on the industry's first complete line of subminiature aluminum electrolytic capacitors, write Technical Literature Section, Sprague Electric Company, 347 Marshall Street, North Adams, Massachusetts.

# VERTI-LYTIC\* CAPACITORS

These space-saving Type 89D 'lytics are designed for easy manual upright mounting on printed wiring boards. Keyed terminals assure fast mounting and correct polarity. No reworking on the assembly line. Sturdy pre-molded phenolic shell with resin end-fill gives excellent protection against drying-out of the electrolyte or the entry of external moisture. The phenolic case eliminates the necessity for additional insulation. Reasonably priced for mass production receivers. Engineering Bulletin No. 3060 lists standard ratings with performance data.

# Cera-lytic\*

The ideal capacitor for applications where low cost is the primary consideration is Sprague's new Type 31D. Capacitor sections are housed in a dense steatite tube with resin end-fill to provide protection against mechanical damage and atmospheric humidity. This construction results in excellent capacitor performance for all miniature electronic circuits. Size for size, they're the smallest the industry has produced in a ceramic-cased aluminum electrolytic. Engineering Bulletin No. 3010 details standard ratings and gives performmance data.

# Volume output makes Tung-Sol/Chatham 6528 available for widespread use!

Enthusiastic acceptance of the 6528 Twin Power Triode forced rapid expansion of production quotas, in turn resulting in lower manufacturing costs. These savings are reflected in lower prices to the user making Type 6528 economically practical for a vast number of new industrial and military applications.

Type 6528 requires fewer passing tube sections . . . permits lower range control circuits . . . and combines low internal tube drop with top control sensitivity — a definite advantage over previous series regulators. Also, 6528 triodes may be used in parallel or separately. This simplifies circuitry . . . saves space.

DESIGN FEATURES OF TUNG-SOL/CHATHAM TYPE 65281

- 1 Hard glass envelope permits full out-gassing . . . takes higher temperatures without gas evolution . . . increases thermal shock resistance.
- 2 Zirconium-coated graphite anodes assure excellent gettering. Graphite virtually unaffected by heat.
- 3 Oversize cathodes provide adequate emission reserve . . . eliminate standby deterioration.
- 4 Extra-rugged grids. Sturdy chrome-copper side rods support gold-plated molybdenum lateral wires.
- 5 Overall ruggedness. Metal snubbers and ceramic insulators support mount. Heavy button-stem has rigid support leads.

Tung-Sol Electric Inc. specializes in special-purpose tube development . . . can match any design requirement you have. # FREQUENCY, TACHOMETRY INSTRUMENTS

#### -hp- 500B Electronic Frequency Meter

Model 500B is a rugged, precision instrument widely used for direct-reading laboratory or production line measurements of ac frequency from 3 cps to 100 KC. With -hp-508A-D Tachometer Generators or -hp-506A Optical Tachometer Pickup, the 500B also provides direct tachometry readings.

Typical applications include rf signal beat frequency comparisons, crystal frequency deviations, audio frequency and FM measurements, oscillator stability, machinery rotational speed, average frequency of random events, checking vibration or torsion in gear trains, etc.

Model 500B has an expanded scale feature permitting

any 10% or 30% of selected range to be viewed full scale. It also offers a pulse output synchronous with an input pulse for measuring FM components of input signals or syncing a stroboscope or oscilloscope. Readings are independent of line voltage, input signal or vacuum tube variations. \$285.00.

-hp- 500C Electronic Tachometer Indicator

Model 500C is identical to 500B except for meter calibration which is in rpm for greater convenience in tachometry measurements. With appropriate -hp- transducers (506A or 508A-D series), -hp- 500C will measure rpm from 15 to 6,000,000 rpm in 9 ranges. \$285.00.

#### -hp- Rotational Speed Transducers

#### NO MECHANICAL CONNECTION

-hp- 506A Optical Tachometer Pickup measures speeds 300 to 300,000 rpm of moving parts which have small energy or can not be connected mechanically to measuring devices. Employing a phototube and operated by reflected-light interruptions from light and dark areas on a shaft, -hp- 506A may be used with -hp-500B Electronic Frequency Meter, -hp-500C Electronic Tachometer Indicator, -hp-521A or 521C Electronic Counters, and similar instruments. Output voltage is 1 volt rms minimum into 1 megohm; light source is a 21 candlepower, 6 volt automotive bulb; phototube is Type 1P41. \$125.00.

The G-E Power Tube Microwave Laboratory is located at Stanford Industrial Park, Palo Alto, California where it was one of the Park's pioneer installations. Its staff of scientists and engineers has the advantage of technical exchange with Stanford University faculty and research staffs, as well as with General Electric's own Research and General Engineering Laboratories.

## RADAR CAPABILITY BROADENED BY HIGH-TUBES DEVELOPED AT GENERAL ELECTRIC

Development of advanced high-power, pulsed traveling-wave tubes at the Power Tube Department's Microwave Laboratory at Palo Alto, California, is contributing substantially to the broadening of radar frequency ranges. Vital accomplishments provided are: high pulse powers over wide instantaneous bandwidths; periodic permanent-magnet focusing; novel, light-weight, rugged tube structures. In addition to systems-oriented work at X band, developments are progressing at L, S, C, and K bands.

Traveling-wave tube pioneering is only one of a broad range of microwave activities being conducted at the G-E Microwave Laboratory. The Laboratory's fields of activities are applied research, advanced development, and product design in microwave tubes and microwave techniques. All development work is done with an eye to practical, economical manufacture—thus minimizing the time lapse between prototype development and quantity production—and to the realistic tube needs of future microwave equipment. Technical inquiries pertaining to advanced microwave tube development invited. Power Tube Department, General Electric Company, Schenectady, New York.

\*

Professional opportunities available for engineering and scientific personnel. Inquiries invited.

Pulse Engineering, Inc., Dept ED, 2657 Spring St., Redwood City, Calif.

# Purified Silicon

#### cuts the guesswork out of doping

Now semiconductor-device manufacturers can dope silicon to the exact resistivity range desired without complicated doping procedures. New Sylvania purified silicon ingots are swept clean of virtually all impurities and are essentially uncompensated since only minute amounts of boron remain. Because the boron is present in known quantities, the amount of doping agent needed to obtain an exact resistivity range can be easily calculated. As a result, there is a higher yield of usable material per doped crystal.

Sylvania p-type purified silicon is available in three standard grades based on minimum resistivity—1, 40, and 100 ohm cm. The ingot is 50 mm

half round in cross section by 25-30 cm (10-12 in) in length. It weighs approximately 15 g/cm (40 g/in) which is practically of theoretical density.

In addition, Sylvania supplies germanium and silicon in cast rods 4 mm to 15 mm in diameter from 8" to 18" in length. Undoped single crystals and polycrystalline purified ingots and as-reduced ingots of n-type germanium are available, also. Both silicon and germanium are available in cut pieces to fit crystal-growing boats or crucibles of all types. Contact Sylvania's Chemical and Metallurgical Division for further information on new purified silicon and on the full line of other semiconductor materials.

#### Flexible Terminal Blocks

Have self-locking screws

Imported from West Germany, Flex-o-Block terminals are made of unbreakable, nonporous, completely flexible vinyl plastic. Blocks are in strips of 12 that can be cut with a pocket knife. Screws, enclosed in plastic molding, have a tapered head which gives locked-in protection without washers. Resistant to environments, the terminals withstand temperatures from -65 to +100 C. Resistance is  $2.5 \times 10^{15}$  per in.; dielectric constant is 3.5 at 60 cps. Units come in 10, 20, 30, and 50 amp capacities.

#### **Composite Transistors**

High gain

These composite transistors and diodes feature stability, high gain, and the elimination of ancillary circuitry. The 2N626 npn and ARA-25P ppp power transistors are for use in circuits where high impedance driving sources exist in common emitter, common base, or common collector configurations. The ARA-25N-H pnn and ARA-25P-H npp power transistors are germanium-silicon power hook collector transistors designed to be used in their stable configurations. The ARA-D1528 shunt regulating diode consists of a Zener diode coupled to a high power composite transistor.

# **BASIC RELIABILITY**

Starts in the nerve system...wire!

Eliminate the possibility of wire failure and you've licked the first "if" of circuit functioning.

At Hitemp Wires, Inc., Teflon\* wire, cable and tubing must pass grueling countdowns. Rigid inspections screen all incoming raw materials. During and after insulating with the most modern equipment, more than 30 electrical, mechanical and environmental tests assure uniform high quality.

Such exhaustive procedures of continuous inspection and quality control are unequalled in the wire industry.

These extra steps, however, are well worth the time and effort. They give you a built-in safety factor—the factor of *predictable* dependability. Hitemp Wires, Inc. products more than meet MIL specifications.

The ability of Hitemp Wires, Inc. products to exceed the exceptionally high requirements of the military in virtually all key missiles—guarantees wire, cable and tubing users in other fields the highest order of basic reliability. Write Department 968 today for more information and our newest catalog.

MICROPOTS MICRODIALS MOTORS

ELECTRONIC DESIGN • September 17, 1958

Where to lay the scalpel is rarely the result of engineering considerations alone. Those responsible for the successful operation of the system must consider: (1) the requirements of the system as a whole, and (2) the ability of suppliers to furnish that level of subassemblies or units which fulfill overall system requirements with maximum efficiency.

In the field of servo control systems and assemblies, Daystrom Transicoil has demonstrated the necessary engineering and production experience to achieve full optimization of sub-systems and assemblies—involving the use of servo motors and motor generators, gear trains, synchros, servo ampli-

fiers, servoed indicators, and other servo components. Our work, to date, has included missile guidance assemblies, autopilot subsystems, radar control systems for aircraft, position display devices for shipboard navigation, air-borne camera control assemblies, flight control assemblies for supersonic aircraft... and our experience is growing as fast as the servo field itself.

The specialized help you need to turn modern system requirements into optimized working sub-systems and assemblies is part and parcel of our business. Contact us direct or through our local representative. And if you need servo motors and motor generators in a hurry, check into our 24 Hour Service.

KEEP UP-TO-DATE ON MAGNETICS

# Now-guaranteed practical inductance limits for regular and frequency-stabilized permalloy powder cores

Call them frequency-stabilized or temperature stabilized, the important thing about these new molybdenum permalloy powder cores made by Magnetics, Inc., is our *guarantee* of core inductance within realistic limits. You can write—right now—for these guaranteed limits.

Filter circuit designers will take note that these guaranteed limits for permalloy powder cores are far tighter than those published before. Note also that they are guarantees on inductance which is the parameter of chief concern to the core user rather than on permeability.

This can save you dollars on your production line-by cutting down on adjustment of number of windings on coils. And you know, too, that temperature stabilization eliminates difficult compensation problems.

But did you know that we guarantee these new inductance limits for all of our permalloy cores, whether stabilized or not? For all the facts, write us at Magnetics, Inc., Dept. ED-47, Butler, Pennsylvania.

CIRCLE 125 ON READER-SERVICE CARD

## World's Biggest Eater Dines Without Interruption

Typical insulator and insulating bolts used on power shovels.

You are looking at 3 million dollars' worth of power shovel, a 14-story monster capable of biting off 70 cubic yards of dirt at a clip.

Continuous operation is essential because downtime on a shovel of this size could top 500 dollars an hour. Reliability is shared by many interrelated parts. Some are made of Synthane laminated plastics.

Why Synthane? Because Synthane laminated plastics have the right combination of properties—dielectric strength, mechanical strength, and ease of machining. And Synthane uses only first-quality raw materials, watches every step in the production and fabrication of the laminate,

is deeply concerned about delivery requirements.

Good materials, competent people, excellent tools and workmanship may not guarantee reliability but they're strong assurance of it.

If you are interested in a reliable source of laminated plastics—sheets, rods, tubes, or completely fabricated parts, write for an interesting catalog or call our representative near you.

Experience—the added alloy in A-L Stainless, Electrical and Tool Steels

# GUARANTEED PERMEABILITY... and at higher values than old average values in AL-4750

AL-4750 nickel-iron strip now has higher permeability values than ever before . . . and the new, higher values are guaranteed. For example, using the standard flux density test, at 40 induction gausses, AL-4750 now has 57% higher permeability than in the past. And permeability values are guaranteed.

ability values are guaranteed.

This guaranteed permeability means greater consistency and better predictability for magnetic core performance...permits careful, high performance design.

The improvement in AL-4750 didn't just happen. It is the result of Allegheny's electrical alloy research and production program in nickel-bearing steels. A similar improvement has been made in AL Moly Permalloy. And research is continuing on silicon steels including AL's famous Silectron (grain oriented silicon steel), as well as on other magnetic alloys.

Another service of Allegheny Ludlum includes complete facilities for the fabrication and heat treatment of laminations. Years of experience in AL's lamination department means that Allegheny Ludlum has encountered and solved most problems common to core materials. This practical know-how is available to all. Call us for prompt technical assistance. Write for blue sheet EM-16 for complete data on AL-4750.

# New Humphrey dual-rate gyros do the work of two units

Now important reductions in the space required for instrument and control packages can be made with the introduction of a new Humphrey rate gyro that replaces two ordinary gyros. The new design utilizes a single motor to drive two separate wheels in one unit. With this new development, it is possible to measure rates about two different axes with an RG-18 Series Gyro or cover two different rate ranges about the same axis with a single RG-20 Series instrument.

RG-18 gyros should find widespread use for applications now requiring two instruments. For example, one unit could be used to measure both pitch and yaw. The RG-20 Series, with its two different rate ranges, may be applied to instrumentation systems where greater accuracy is required. For example, a single unit can be furnished to cover the rate ranges from 0–20 degrees/second and from 0–200 degrees/second. In effect, you expand the dynamic range of your instrumentation system from 100 to 1 to 500 to 1. This expanded scale gives you far greater accuracy.

The new rate gyros are built with two independent pick-offs—one for each axis or one for each range. They meet tough environmental conditions, such as temperature from -65°F to 180°F while operating, relative humidity 100%, unlimited altitude and excellent resistance to acceleration, vibration and shock. Phone or write today and let the kind of engineering that developed these new dual-rate gyros go to work for you.

# Quick-Opening Fasteners

# Selecting Small Fastenings for Metal Closures

"Use captive fasteners wherever feasible . . . Avoid the use of loose washers and loose nuts . . . Fasteners on equipment covers should be operable either with no tools or with standard hand tools"\*

(John D. Folley, Jr. & James W. Altman, Research Scientists, American Institute for Research)

#### Quarter-Turn Fastener

Lion Fasteners open and close with a ½ turn, hold sheets tightly under the compression of a rugged spring. Quickly operated and fully retained in the outer panel, they are approved under U. S. Government military specifications. Stud and receptacle float for easy alignment and simplified hole preparation. Flush, oval, wing, knurled, ring, and key head styles available. Sizes—No. 2, No. 5, and High Strength for extra heavy duty.

Cabinet Latch

Just drill a hole, push the fastener stem through, and slide the special push-on clip into place. No welds, screws, bolts or rivets: the fastener is permanently installed in seconds!

Adjustable to any grip length or panel

Adjustable to any grip length or panel thickness, the pawl is fixed in place by a single set screw. The fastener's brightly finished knob is set off by a plated washer. Also furnished with screwdriver operated flush head.

#### Adjustable Panel Latch

Small doors and panels can be fastened with greatest speed and lowest cost with the Southco Adjustable Latch.

The entire fastener is quickly installed through two holes punched in the door; no bolts or rivets are needed.

It operates with a quarter turn, requires no striker plate. An extra twist after the nylon pawl is engaged pulls up the door to form a seal and eliminate vibration.

Available with wing, knurled, or Phillips head.

hinged panels the Southco Arrowhead Latch is recommended. It locks or opens with a quarter turn yet occupies less than ½" inside space.

Doors are held under spring tension—

Doors are held under spring tension—a push against the arrowhead knob relaxes this tension, allows operation with fingertip ease. Drill a single hole for installation—no fastening to the door is necessary. No striker plate is needed.

Pawl stop is eliminated—arrowhead shows at a glance exact position of pawl.

Free Fastener Handbook

Send for your free copy of Fastener Handbook No. 7, just released. Gives complete engineering data on these and many other special fasteners. Fifty-two pages, in two colors.

Write on your letterhead to Southco Division, South Chester Corporation, 235 Industrial Highway, Lester, Pa.

... for as little as \$148.50

# New K&E Paragon Auto-Flow gives you faster, easier drafting 5 ways...

The first time you use it, you'll know that K&E's light-weight Paragon® Auto-Flow™ Drafting Machine is a truly great advance in working ease and range. Here are 5 specific reasons why.

It's more versatile. Stays in perfect balance at any board angle, from vertical to horizontal. No adjustments needed, except a simple turn of a tension spring wheel for angles below 15 degrees.

It's more compact. The balance is built right into the machine itself. There's no need for counterbalances that project over the top of the board.

It's better made. Glides smoothly and easily on finely-ground, stainless steel rails with K&E precision and quality in every detail.

It's more adaptable. You get a full sweep of every size of board.

It's far easier to use. The scales move smoothly, at the slightest touch. Long lines up or across can be drawn in a single motion. Scales lock in place to eliminate "drift". Greater rigidity produces truer lines.

The 30" by 40" Auto-Flow costs only \$148.50... the 36" by 60" only \$160. All standard sizes; left-hand models available. Mail coupon for details.

## KEUFFEL & ESSER CO. Dept. ED-9, Hoboken, N. J.

#### WESTON INSTRUMENTS: STANDARDS OF STABILITY IN SCIENCE AND INDUSTRY

#### WESTON'S BROAD LINE OF RUGGEDIZED INSTRUMENTS WILL TAKE THEM EASILY IN STRIDE

New design concepts, new materials and new production techniques . . . these are the ingredients of Weston's '58 line of Ruggedized Instruments. Now, more than ever, they insure dependable, accurate service under extremes of shock, vibration, temperature, humidity and general abuse.

Mechanisms are mounted on metal decks. The decks and terminals are then molded into a specially compounded, shock-resistant rubber. This results in a well-insulated, leakproof, and virtually breakproof seal. Damage from impact to jewels and pivots is eliminated through spring-backed mounting. Tough

plastic windows make the use of zero correctors practical. The entire mechanism is housed in a rigid steel case which provides excellent shielding against external magnetic fields. The instruments may be mounted interchangeably on either magnetic or non-magnetic panels without loss of accuracy.

Consult your local Weston representative for complete details... or write for Catalog A-38. Address: Weston Instruments, Division of Daystrom, Inc., Newark 12, N. J. In Canada: Daystrom Ltd., 840 Caledonia Rd., Toronto 10, Ont. Export: Daystrom Int'l., 100 Empire St., Newark 12, N. J.

#### NEW CMC DUAL PRESET COUNTER FOR

coil winding...motor speed control...shearing to length...batching, packaging, and stacking by number...variable pulse interval generation...process programming...measurement of elapsed time between selected number of events...and used with a CMC frequency meter, very accurate frequency measurements.

Only CMC's new
Dual Preset Counters have

Modes of Operation

New CMC Dual Preset Counters provide output information at any two pre-selected counts within the capacity of the unit up to 40 kc. Input pulses are obtained from any standard transducer. With an 0.05 v rms input sensitivity, external amplifiers are seldom necessary.

CMC's unique digit circuitry prevents miscounting and extends the capacity of the instrument beyond its apparent range — in some applications, a 4 decade CMC instrument offers the same operating performance as other 5 decade types.

#### KEY SPECIFICATIONS

DECADES 3, 4, 5 or 6 • COUNT CAPACITY Up to 1,000,000 INPUT FREQUENCY To 40 kc • OUTPUT Pulse and relay simultaneously • OPTIONS Rack mount, 400 cps operation, 5 digit mechanical register, 5 mv preamp, digital printer or inline readout output • PRICE 3 decade \$615; 4 decade \$715; 5 decade \$815; 6 decade \$915.

CMC engineering representatives are located in principal cities. After you've checked the key specifications, give your nearest CMC representative a call. He'll be happy to arrange a demonstration. For complete technical information, please write Dept. 199.

5528 Vineland Ave. • No. Hollywood, Calif. Phone Stanley 7-0401 • TWX: NHOL 8290

CIRCLE 313 ON READER-SERVICE CARD

#### MODES OF OPERATION

With RECYCLE switch in the OFF position, output information is obtained at both the first and second preset selections but the counter continues to totalize, until the maximum count capacity of the instrument is reached. The counter then resets to zero and repeats the cycle as above.

With RECYCLE switch in the A position, (a) output information is obtained from the A channel and the instrument recycles on A. (b) If the B channel selected number is less than the A channel number, the unit will provide output information at B and continue on to the A channel selection as above.

With RECYCLE switch in the B position, (a) output information is obtained from the B channel and the instrument recycles on B. (b) If the A channel selected number is less than the B channel number, the unit provides output information at A and continues on to the B channel selection as above.

With RECYCLE switch in the A & B position, the instrument provides output information and recycles alternately on the A & B channels. For example, when the unit is recycling on A, B is ignored and when recycling on B, A is ignored. This position is ideal for generating a chain of variable spaced pulses.

KAY Vari-Sweep

> MODEL 400 Cat. No. 867-A

#### WIDER RANGE, ALL-ELECTRONIC SWEEPING OSCILLATOR, OR (with sweep off) CONTINUOUSLY TUNED CW SIGNAL SOURCE

The new Kay Vari-Sweep Model 400 is a highly versatile laboratory sweeping oscillator and signal source. Its wider range of continuous frequency coverage is combined with accuracy and performance standards previously associated with limited, fixed-frequency-band sweeping oscillators. The high RF output is held constant over the range by a fast acting AGC circuit. A variable sweep rate down to 10 cps permits checking of high-Q circuits.

#### SPECIFICATIONS

Freq Range (CW or Sweeping): Fundamental frequency, 15-470 mc, cont. variable in 10 switched overlapping bands. Direct-reading frequency dial.

Sweep Width: 60% of center freq to 50 mc; at least 30 mc max 50-400 mc; approx. 20 mc max above 400 mc.

Sweep Rate: Cont. variable, 10-40 cps; locks to line freq.

RF Output: 1.0 V rms (metered) into nom 70 ohms (50 ohms on request) to 220 mc; 0.5 V rms to 470 mc. AGC'd constant over

widest sweep and entire range to  $\pm 0.5$  db. Attenuators: Switched 20, 20, 10, 6 & 3 db plus cont. variable 6 db.

Sweep Output: Reg. sawtooth in sync with oscillator. Amplitude 7.0 V approx.

Power Supply: Input approx. 100 watts, 117-V (±10%) 50-60 cps ac. B+ electronically

Dimensions:  $9\frac{1}{9}$ " ×  $19\frac{1}{2}$ " × 13".

# AHEAD AGAIN

U. S. Radium's Newest Instrument Dial

A current problem in integral instrument lighting is that of obtaining, at reasonable cost, a dial for a particular unit which will light within the brightness ratio spec of MIL-L-25467A. Since different instruments will have different lighting systems and will require different dial configurations and indicia, the dial contractor must be able to vary the opacity of his dials in order that the finished instrument assemblies will light to MIL spec, regardless of the internal light levels and the number and position of the lights.

U. S. Radium's new production process for MIL-L-25467A dials permits the variation of the opacity factors of the background and indicia within wide limits, to provide a compatible instrument-dial assembly. It also allows piece-to-piece uniformity which excels conventional methods for meeting this spec, and at lower unit cost. These advantages, plus the availability of U.S. Radium's light engineering service during the formative stages of light housing design, provide a foolproof working method for eliminating light engineering headaches, cutting costs and speeding delivery.

For information, contact Department D9.

CIRCLE 158 ON READER-SERVICE CARD

The Saucer Fan represents an entirely new design concept whereby the driving motor is built within the propeller hub limiting its axial length to the minimum measurement required by a highly efficient motor. Ideally suited for tightly packed electronic packages, where space is critical, the Saucer Fan will provide cooling air to the amount of 280 cfm. Power requirement is 115 vac. 50-60 cps, 1 0.

The fan's pressure performance is tailored to the requirements of a modern, washable dustfilter. "Servo type" mounting flanges at each end of the venturi ring permit simplicity of mounting without loss of space. Direction of airflow may be easily reversed by turning the fan end for end. Electrical connections are made to a compact terminal block.

# New Ruggedized Westinghouse Image Orthicon!

DURABLE NEW WL-7198
WITHSTANDS SEVERE
ENVIRONMENTAL CONDITIONS,
SHOWS NO DEGRADATION
AFTER 30 G'S!

Now Westinghouse has developed an image orthicon tube that's rugged enough to withstand 30 g's... yet sensitive enough to perform efficiently at low light levels. The new WL-7198 is ideal for military, industrial and scientific applications subject to extreme environmental conditions.

#### TYPICAL CHARACTERISTICS OF THE WL-7198 ARE:

- Vibration: (1) Operable throughout MIL-E-5272A Procedure I (10 g's from 50 to 500 cps)
  - (2) 350 lines horizontal resolution at 5 g's from 50 to 500 cps with 3 x 10<sup>-2</sup> footcandles on photocathode.

Shock: No degradation after 30 g's.

Low light level performance: 250 lines minimum resolution 3 x 10<sup>-4</sup> foot-

candles on photocathode.

Sample quantities of the WL-7198 are available for immediate delivery.

WESTINGHOUSE ENGINEERS WILL HELP YOU SOLVE YOUR IMAGE ORTHICON PROBLEMS UPON YOUR REQUEST.

# NEW Power Ferrite for Flyback Transformers offers

- Higher Flux Density
- Lower Core Losses
- Higher Curie Point

Now, with Allen-Bradley's new Class W-04 ferrite, you can design smaller flyback transformers with smaller cores. This saves space... saves weight...saves copper...and you have a saving in over-all cost!

Specify Allen-Bradley's new W-04 ferrite for your flyback transformers. The table below compares its superior properties with Allen-Bradley's "premium quality" W-03 ferrite.

Write for complete data, today!

a LOT of Relay in a little space

This latest Automatic Electric achievement compacts all the features of the famous Class "B" relay in minimum space and weight—with no sacrifice of quality or ruggedness.

#### LOOK AT THE IMPORTANT FEATURES THIS NEW CLASS "E" OFFERS:

miniaturized; telephone-style base mounting for rear-connected wiring heavy-thickness armature arms prevent loss of stroke with large pileups heavy-duty backstop that won't break or wear out adequate terminal clearances for easy wiring long-life, lubricant-retaining bearing arranged to provide a visual check of the heel-piece airline setting without disturbing the adjustment twin contacts standard; all springs bifurcated for maximum independence sturdy, strain-relieved heelpiece insures stability of adjustment 13 springs can be provided in certain applications

#### Class "E" Relays are available in the following series:

EQA—Quick Acting ESA—Slow Acting\*
ESO—Slow Operate EFA—Alternating Current

ESR-Slow Release EMS-Snap Action Contacts

\*slow operate and slow release

Class "E" Relays can be supplied plug-mounted (with or without cover) or hermetically sealed (maximum 4 springs per pileup) in enclosure AE-3300.

For more information, call or write Automatic Electric Sales Corporation, Northlake, Illinois. *In Canada:* Automatic Electric Sales (Canada) Ltd., Toronto. *Offices in principal cities*.

New Class "E" Relay

99% pure isn't pure enough — the relay iron we use at Automatic Electric must meet specifications of 99.8% purity, including, for example, carbon content limit of .02. To obtain highest magnetic permeability, material is treated for periods up to 7 hours in roller hearth annealing furnaces. Highest standards of quality control insure the well-known dependability of AE Relays and Switches.

Memo to: COMPONENTS MANUFACTURERS

Electronics business is good in New England. Are you getting your share from the Nation's sixth largest electronic market?

Did you know that the top 10 giants in the electronic industry which serve the computer, missile, and aircraft fields all have large plants in New England?

ATLANTEX CORPORATION is an established manufacturers representative (New England and Long Island) with 15 years of successful marketing. Successful because its team of graduate sales engineers are thoroughly trained to sell at the applications and design engineers level. This seasoned group gives you the equivalent of 4 high priced sales engineers, with complete and thorough coverage.

If your components meet the highest standards for quality and performance why not write or call . . . attention of Paul Wallins.

TYPE DCM-99K-1 DC MODULATOR

# tired of CHOPPER

troubles?

This new, hermetically sealed, single pole, double throw DC MODULATOR is virtually free from DC drifts. Each individual unit has less than 5 microvolts DC offset and drifts less than 2 microvolts over long periods of time. Normal contact dwell time is 55%, other dwell times being available. Constancy of dwell time better than 2% for first 1000 hours operation, less change afterwards. Life expectancy 10,000-25,000 hours.

Due to their rigid production standards these modulators are freely interchangeable, normally not requiring re-zeroing after replacement.

A new magnetic driving system provides unprecedented freedom from magnetic and electrostatic interference between coil and contacts making hum immeasurably small. A radically new contact design and contact treatment keeps RMS contact—noise voltage—generation well below 1 uV.

This DC modulator is used in the most stable amplifiers and DC vacuum tube voltmeters available on the market today.

#### **NEW PRODUCTS**

#### **Preset Counters**

Modular design

Series 320 preset electronic counters are available in every size from 2 to 6 digits. They consist of a pluggable amplifier and control unit plus any combination of pluggable 2 and 3 decade modules. Maximum rate is 5000 counts per second.

Erie Resistor Corp., Dept. ED, 644 W. 12th St., Erie, Pa.

CIRCLE 214 ON READER-SERVICE CARD

## RF Power Dividers

General purpose 100 to 200 mc and 200 to 400 mc dividers for connecting 2 to 12 loads to one source. Input vswr is less than 1.25; loss about 0.1 db; power rating 500 w at 150 F.

Adams-Russell Co., Inc., Dept. ED, 292 Main St., Cambridge 42, Mass.

CIRCLE 215 ON READER-SERVICE CARD

Stitched Wiring Modular circuit method

In this method, wire is stitched to a standard terminal board with

eyelets or eyelet terminals to form complete circuits. Insulating sleeves allow wires to be crossed so that all wiring is stitched to one side of the board. Changes may be made by cutting wires and soldering in new leads

Electronic Techniques, Inc., Dept. ED, 13761 Saticoy St., Van Nuys, Calif.

CIRCLE 216 ON READER-SERVICE CARD

#### Mercury Push Button Switch

No contact bounce

Trapped pools of mercury slide in and out of contact to operate this push button switch. The spdt break before type unit has no contact bounce or chatter. It mounts in any position and stands 15 g shock and vibration.

Electrosonic Engineering Co., Inc., Dept. ED, 2120 Pontius Ave., Los Angeles, Calif.

CIRCLE 217 ON READER-SERVICE CARD

Directional Couplers

For 100 to 1000 mc use

For 100 to 1000 mc use, series DC directional couplers come with type N, BNC, and TNC connectors. Directivity is 20 db minimum above coupling factor. Vswr is 1.3 maximum in the primary arm and 1.5 maximum in the secondary. Coupling factor is 30 db at 100 mc and 10 db at 1000 mc.

Maury & Associates, Dept. ED, 10373 Mills Ave., Pomona, Calif.

#### Accelerometers

Tri-axial

Three mutually perpendicular sensing elements are mounted in these small accelerometers. The units have 25 kc frequencies and 5 to 9 mv per g sensitivities. Model 2230 operates to 200 F; model 2243 to 500 F.

Endevco Corp., Dept. ED, 161 E. California St., Pasadena, Calif. CIRCLE 219 ON READER-SERVICE CARD

#### **Shorting Switch**

Assures one position

Switch shorts out every position but the one in use. Useful in the metering of a single position or for the gathering of pertinent information on it.

The Daven Co., Dept. ED, Livingston, N. J.

CIRCLE 220 ON READER-SERVICE CARD

#### **Dual Servo Multiplier**

Modular construction

Providing a static nulling error of 0.02 per cent, the DLI-101 servo multiplier has two channels, each of which multiply three variables by a fourth. Its automatic gain control feature maintains constant loop gain for reference voltage variation in the 2 to 100 v range. The unit is composed of Digitrol plug-in building blocks.

Electro Precision Corp., Dept. ED, P.O. Box 669, Arkadelphia, Ark.

## Bendix - Pacific SUBCARRIER OSCILLATOR

Here is the all-new Bendix-Pacific TOE-40 Voltage Controlled Oscillator which offers new instrumentation accuracy and new freedom from inflight calibration. It is characterized by a high degree of frequency and sensitivity stability with exceptional linearity. In addition, the new Bendix-Pacific unit is reduced in size to almost half that of former equipment.

#### CHARACTERISTICS:

Available Bands: All standard IRIG telemetering bands for channels 3 through 18 & A through E. Input Ranges: 0 to +5V DC, 0 to -5V DC,  $\pm 2.5$ V AC, 0 to +3V DC, 0 to -3V DC,  $\pm 1.5$ V AC. Bands 3 through 18 (3 and 5 volt ranges)—1 megohm

Input Impedance: Bands A through E (5 volt range)—1 megohm
Bands A through E (5 volt range)—1 megohm
Bands A through E (3 volt range)—600 kilohm
Input Intelligence Frequency Response: Within ±0.5 db from zero to five times the IRIG channel signal frequency.

Output Amplitude: 2.0 volts rms (Min.) open circuit.

Signal Output: 200 kilohms.

Monitor Output: 25 kilohms nominal.

Output Distortion: Less than 1% at maximum voltage over the bandwidth.

Linearity: Less than  $\pm 0.75\%$  bandwidth deviation from straight line.

Weight: Approximately 7.5 oz.

Bendix-Pacific provides a complete telemetering service consisting of transmitting and receiving components, application engineering, systems and field services.

Write for complete information.

PUBLISHED BY ROME CABLE CORPORATION, ROME, N.Y. PIONEERS IN INSTRUMENTATION CABLE ENGINEERING

POLITE POLICEMAN—Tomorrow's vehicle control system might parallel the electronic traffic control system of RCA's David Sarnoff Research Center. Transistorized detector units at the Center count passing cars on roads, measure their speed, and flash a polite warning saying "Slower Please" to drivers exceeding the posted speed limit.

AROUND THE MOON IN 208,000 WATTS—Data-seeking rockets and missiles present a new challenge to telemetry equipment. For example: with present equipment, Army missile experts estimate it would require 208,000 watts to relay a TV panorama of the moon back to earth. Needed: new concepts of conveying data through space.

INSTRUMENTATION CABLE BULLETIN—This 8-page illustrated bulletin discusses cable insulation and jacketing material and lists typical multi-conductor cable constructions available for use with telemetering equipment, data recording equipment, circuit control testing and electronic computers. Every design engineer working with electrical

cable should have a copy! To obtain your *free* copy write to Rome Cable Corporation, Dept. RCD-400, 421 Ridge Street, Rome, New York.

**WEE WIRING**—Printed wiring boards, already small, might get even smaller soon! How? By eliminating the land area around the holes in the board. This is being done experimentally by some concerns by using plated-through hole techniques. Full-scale production of the new, smaller boards may not be far off.

THE SATELLITE SCOREBOARD—At the date of this writing, the batting averages in the ORBIT LEAGUE looked a little onesided: ARMY (with 3 out of 4 EXPLORERS in orbit) .750\*, NAVY (with 1 out of 6 VANGUARDS up) .167.

\*(This, incidentally, was better than Stan Musial's average of .339 at the same date.)

**CABLEMAN'S CORNER**—Not too long ago, a new TV quiz program, entitled "Anybody Can Play," made its debut. No special knowledge was necessary—anyone could answer the questions.

Fine—for TV quiz programs. Dangerous—if applied to cable engineering and manufacture. For 100% reliability in multi-conductor cables—you must call on a specialist!

Why? Here are the reasons. If a cable is to be reliable, it must be: 1. Designed by an experienced cable engineer with a working knowledge of instrumentation problems. 2. Constructed of quality material—with the emphasis on solving the need—and not on the price. 3. Controlled and thoroughly tested during production. 4. Backed up by a reliable manufacturer who will stand firmly behind every cable produced.

Don't sacrifice reliability in cables for price. Call on a Cable Specialist. Our address is Rome Cable Corporation, 421 Ridge Street, Rome, N. Y.

#### **NEW PRODUCTS**

Amplifiers
Recording type

These amplifiers are airborne instruments designed to amplify signals from high impedance transducers. Operating at a temperature range of -65 to +240 F, models F-510TU and F-528LU have extremely high input impedance.

Gulton Industries, Inc., Dept. ED, 212 Durham Ave., Metuchen, N.J.

CIRCLE 226 ON READER-SERVICE CARD

#### **Panel Meter**

Highly readable

Panel meter MM-5 occupies panel space of conventional 4-5/8 in. meters and mounting space of ASA/MIL 3-1/2 in. units, yet provides greater scale length and readability. Tracking can be held to 0.5 per cent of full scale, when plotted linearly or with a protractor reference for deflection angles up to 100 deg.

Marion Electrical Instrument Co., Dept. ED, Grenier Field, Manchester, N.H.

CIRCLE 227 ON READER-SERVICE CARD

Transformers
Miniature

Twenty of these transformers fit into a cubic inch. Suited for missile and transistor circuits, they are uncased, encapsulated, or molded plugin type.

Palo Alto Engineering Co., Dept. ED, 620 Page Mill Rd., Palo Alto, Calif.

Now you can make fast, drift-free measurements of voltage, current and resistance with L&N's 5620 R-I-E Meter. Applications include: voltage measurements of vacuum tube electrodes . . . current measurements in photo-cells, ion chambers . . . resistance measurements of high value resistors, volumetric or surface resistance of samples of small sizes, etc.

Ranges—Volts D-C (4): 0-0.5 to 0-500. Current (6): 0-5 to 0-5x10-5 microamperes. Resistance (6):  $2x10^2$  to  $2x10^8$  megohms.

limits of Error—Current and voltage range,  $\pm 3\%$  of full scale. Resistance range,  $\pm 6\%$  of reading for meter reading of 20 or lower.

Amplifier Output—For use as pre-amplifier for Speedomax® G or H 10 mv Recorders. Provides 10 mv across  $10\Omega$  corresponding to full scale on any selected range.

Controls—Range Switch: 11 positions. Function Switch: 5 positions. Polarity Reversing Switch. Voltage Key: Internal power supply, 10 or 100 volts.

Power Supply—120 volts, 50 or 60 cycles.

Case—Metal,  $7\frac{1}{2}$ " (h) x  $10\frac{1}{2}$ " (w) x  $10\frac{1}{4}$ " (d), with cover.

Price—\$440.00, f.o.b. Phila. or North Wales, Pa. (subject to change without notice). Specify List No. 5620 when ordering from nearest L&N Sales Office or from Leeds & Northrup Co., 4908 Stenton Ave., Phila. 44, Pa.

RECEIVING TUBE.—The 6/12DT5 9-pin miniature power pentode is for use as a vertical output deflection amplifier in 110 deg TV sets.

Westinghouse Electric Corp., Electronic Tube Div., Dept. ED, Elmira, N.Y.

CIRCLE 235 ON READER-SERVICE CARD

These complete tone generator and tone detector circuits, employing Frahm® Resonant Reed Oscillator Controls and Relays, are available as veritable "building blocks" for your communications system.

Applications for these packaged circuits include: selective calling, remote operation, supervisory control, data transmission, telemetering, and monitoring.

The Tone Generators are complete packaged oscillator circuits capable of supplying any one signal frequency within the ranges of 20 to 250 cps or 250 and 1100 cps, with accuracy of  $\pm 0.15\%$ .

The Tone Detectors or receiving circuits, which employ a Frahm Resonant Reed Relay, operate the contacts of the SPDT relay in the unit when a signal of proper frequency and voltage amplitude is applied to the circuit input terminals. They operate with signals having any one frequency in the range of 20 to 1000 cps.

We particularly encourage your inquiries and correspondence on special applications and problems. Complete details on these packaged circuits as well as specifications, characteristics, etc., of our Frahm Relays and Oscillator Controls are available for the asking. Request Bulletins 33 and 34-EE.

## TRANSISTOR TESTER

Accurately Tests Transistors and Diodes
Tests Power Transistors at High Currents

MODEL 150 TRANSISTOR TESTER Net, \$17950 Tests all transistors, and diodes, within 5% accuracy. Tests power transistors at high currents. Measures Beta with 1 KC a.c. signal. Reads  $\beta$  directly on 0-50 and 0-250 meter scales. Power transistor biased at 0.1 amp. collector current, others at 1 ma. Leakage current,  $I_{\rm CO}$ , is read on 0-2 ma scale for power transistors, 0-50  $\mu\alpha$  and 0-200  $\mu\alpha$  for others. Built-in transistor oscillator and buffer. Accurately tests junction and other diodes for forward to reverse current ratio. Long-life mercury cell supply. Instrument and transistors protected against shorts and burn-outs.

## SHORTED TURNS INDICATOR

Tests Coils for Shorts and Open Circuits

—before assembly

MODEL 100 SHORTED TURNS INDICATOR Net, \$17950

Quickly gives "Go-No Go" indication-for production testing, incoming inspection, or laboratory use. Prevents losses in material and labor by finding shorts and open circuits before coil is mounted onto a relay, transformer or other device. Adjustable sensitivity provides selective testing-permits passing or rejecting coils with any particular number of shorted turns. Actually measures the coil 'Q" but under conditions whereby a small difference in "Q" can easily be detected. Fast, easy to use. Safeguards are built-in. No shock hazard to operator. For a fully automated production line, the relay control circuit may be wired to kick out the rejected coil -automatically. 110-120 volts, 60 cycle AC.

## TEST EQUIPMENT CALIBRATOR

Voltage Accuracy 1% or Better

MODEL 750 TEST EQUIPMENT CALIBRATOR Net, \$5495 Enables you to check and adjust your test instruments with laboratory accuracy. Accurately calibrates VOM, VTVM and other meters, signal generators, and oscilloscopes. Provides: DC and AC voltages for checking voltage ranges—standard resistances from 10 ohms to 10 megohms for checking reliability of resistance ranges—crystal oscillator generating harmonics over 300 mc for use as marker generator. Built-in tone generator for signal tracing amplifiers in all audio equipment. Complete with 5 mc crystal. Operates on 110-120 volts, 60 cycles AC.

% STILL OPERATING

## If you want reliable transformers

...don't overlook this old solution

Right now, you demand more from transformers than ever before. You must have high reliability, even at extreme altitudes, and you need smaller lighter units.

Used, and *proved*, for decades, oilencased transformers should not be forgotten in a search for new methods.

Everyone knows the advantages: effective convection of heat, excellent insulating properties, complete insurance against hidden leaks. Oilsealed types (with a nitrogen bubble) are good, light, high-altitude transformers. Gas-free oil-filled types (with a bellows to allow for heat expansion) withstand very high voltage stresses. Except in the smallest sizes, they save space, too.

You can place several high voltage units close together in a single oil-filled case, and save case weight. Those connections moved inside the case no longer need large insulators. Even the units themselves can be smaller. This all adds up—particularly in high altitude service—to interesting savings in space and weight.

We make all sorts of transformers and special assemblies for the communication industry: encapsulated, cast in epoxy or foam, and just potted in pitch. But oil transformers still have an important place.

Whatever type you need, we'll be glad to hear from you. Our facilities in design, production, and quality control are at your service. Our experience, too.

V.C.

TO AUDIO AMPLIFIER

Patent No. 2,832,828. Sidney E. Levy.

An array of l-f and h-f speakers is designed to permit maximum power transfer from the audio amplifier to the speakers. A simple modification of the circuit permits the selection of the transition frequency of the network. Since audio amplifiers having large negative feedback are essentially constant voltage sources, an increase of power delivered to a load at any frequency requires that the impedance of the load be made low at that frequency. Simple analysis of the invention illustrates how the impedance is reduced for the selected range of frequencies. For low frequencies the two woofers are in parallel since the reactance of the condenser is high and the reactance of the inductance is low. At higher frequencies, the woofers are in series and therefore the combination constitutes a high impedance which permits little power to be delivered by the amplifier. By contrast, for low frequencies, the tweeters are in series and for high frequencies the tweeters are in

shunt. Maximum power transfer to the tweeters is transferred properly at the higher frequencies.

The transition frequency may be selected by modifying the capacitance branch to a resistor and condenser either in series or in shunt.

#### Circuits for Controlling the Peak **Amplitude of Electric Current Pulses**

Patent No. 2,822,470. Ronald Charles Imm. (Assigned to the General Electric Co., Ltd.)

The circuit provides a convenient means to control the peak amplitude of electric current pulses in order to shock excite a pulse modulation system for production of pulses of progressively de-

creasing amplitude. In general, the constant amplitude pulses are produced by pulse generator 21 and tubes 24, 15 and 29 suitably biased and clamped. Transformer 3 and diodes 12 and 13 develop the desired trains of positive and negative decremental pulses.

The constant amplitude pulses which excite the antiresonant circuit of transformer 3 are generated as follows.

Grid 23 is clamped to ground by diode 24. Diode 29 has its plate voltage at about 5 v below ground since cathode 28 returns to -150 v through the preset resistor 17. A positive voltage applied to grid 23 causes diode 29 to cut off and the current flowing in the primary winding is set by resistor 17. When the input pulse terminates, there is an appreciable voltage drop in cathode 18 which causes diode 29 to conduct. As a result all of

the current through resistor 17 is bypassed by diode 29 and triode 15 is cut off so that no current flows through primary winding 7.

Pulse current in winding 7 results in a pair of balanced signals at points 10 and 11. Each of these signals has a damped sinusoidal waveform. Diodes 12 and 13 are biased to pass only those portions of the waveforms which are respectively positive and negative with ground. The ratio of the amplitudes of adjacent pulses is determined by the time constant of the transformer secondary circuit.

#### Phase-Inverter Complementary Transistor Amplifier

Patent No. 2,832,846. Frederick D. Waldhauer. (Assigned to Radio Corporation of America)

A phase inverter comprises two complementary symmetry (opposite conductivity) transistors connected in series to produce substantially balanced output current even though the circuit components are not in precise balance. When the phase inverter is combined with a push-pull output stage, a signal from a single-ended source can be used to control the power delivered to the output load such as a speaker. Complementary transistors have two essential properties: 1. Under normal bias conditions the current which flows in each electrode of a pnp transistor is the negative of the corresponding electrode current in the npn transistor; 2. The polarity of an input signal necessary to increase conduction in a pnp transistor is the opposite of that necessary to increase conduction in an

It follows that when complementary symmetry transistors are connected in series, two signals of opposite phase may developed from a single-ended source. Likewise, the invention demonstrates that when the transistors are connected in series with a single battery, the output currents of the transistors are identical. This follows since the sum of the base and collector currents of one transistor equals the sum of the base and collector current of the second transistor. The series circuit has inherent stability because the collector-emitter impedance of each of the transistors provides dc emitter degeneration for the other tran-

The circuit illustrates the phase inverter consisting of npn transistor 18 connected in series with pnp transistor 8, with emitter 18 joined to emitter 12. A single-ended signal is injected on base 10 of transistor 8 while base 20 of transistor 18 is held at ac ground. The equal and opposite signals are ac coupled to npn transistors 56 and 58 which comprise the push-pull output stage driving the load  $\mathbb{Z}_1$ .

An essential feature of the circuit is that a single power source, battery 28, is required for the phase inverter and pushpull output.

#### **Transistor Switching Circuit**

Patent No. 2,829,281. Adrianus Johannes Wilhelmus, Marie Van Overbeek. (Assigned to North American Philips Co., Inc.)

The circuit facilitates the opening of line 1-2 when a negative gate is applied to terminal 17.

In the absence of a gate at terminal 17, transistor  $T_1$  is conducting and line 1-2 is closed through the low emitter to collector resistance of transistor  $T_1$ .

However, transistor  $T_2$  is nonconducting since the base  $b_2$  is at a positive voltage with respect to both collector  $C_2$  and emitter  $e_2$ .

A negative gate applied to terminal 17 causes transistor  $T_2$  to conduct and

It's the

#### FRAME GRID CONSTRUCTION

that makes the difference!

The frame grid is the closest approach to the ideal "physicist's grid"— the grid with only electrical characteristics but no physical dimensions.

#### It results in:

- higher transconductance
- tighter G<sub>m</sub> and plate current tolerance
- low transit time
- low capacitanceslower microphonics
- rugged construction

Amperex FRAME GRID

Grid Voltage (rms)

crossbraces between these rods. Extremely fine grid wire eliminates the "island effect" usually encountered in conventional tubes with equally close grid-to-cathode spacing. Rigid support of fine wires reduces mechanical resonance and microphonics in the grid.

CONVENTIONAL GRID Grid-to-cathode spacing toler accuracy or grid dimension, obtained by stretching on a mandrel, and or colerances of holes in top an octom mica rod supports. Diameter of grid wire must be largenough to be self-supporting.

the voltage at the base b, becomes positive with respect to that of either collector C, or emitter e, of transistor  $T_1$ . Hence transistor  $T_1$  becomes non conducting and line 1-2 is opened. In addition, transmission signals which may be coupled through the capacitance of emitter e, and base b, are shorted to ground through the low resistance existing between emitter  $e_2$  and collector  $C_2$ .

#### **Pulse Amplitude Discriminator**

Patent No. 2,821,626. Melvin B. Freedman. (Assigned to Tracerlab, Inc.)

The pulse height discriminator has a short recovery time. It is adapted to generate an output pulse of uniform amplitude and duration for each of a random series of positive input pulses in excess of a predetermined threshold. The circuit has application in scintillation detectors used with counting rate meters.

In the quiescent state both triode (or pentode) 33 and triode 36 are conducting in accordance with the voltage E on

the cathode of diode 40. A positive impulse at terminal 30 is differentiated by the input re circuit causing triode 33 to conduct. The negative-going voltage on the plate of triode 33 makes diode 40 nonconducting and also reduces the current of triode 36. As a result, a negative voltage is coupled by condenser 39 to the cathode of triode 33 causing the latter to conduct even more. This action carries the circuit rapidly to a state wherein tube 33 conducts heavily and

tube 36 is nearly cut off. The system remains in this state until condenser 39 has almost assumed the charge required by the new state. Thereafter, the tapering off of the charging current of condenser 39 reduces the voltage feedback and tube 33 becomes less conducting. The plate voltage of tube 33 rises, tube 36 becomes more conducting and the signal cross-coupled by condenser 39 to the cathode makes tube 33 less conducting. A cumulative pile up of voltages in the opposite sense reduces the current of tube 33 until the plate voltage assumes the voltage set the reference voltage E. Now, the determining time constant of the circuit is the product of the capacitance of condenser 39 and the cathode resistances of tubes 33 and 36 in series. Since both tubes are conducting at all times, with consequent low impedance, the time constant can be made very short without recourse to an extremely small capacitor. Likewise, it is apparent that the voltage E sets the threshold below which an applied pulse will not produce an output pulse and this, in effect, permits a convenient means to adjust the pulse discriminator level.

gram contains cathode 11, accelerator 14, limiter grid 18, gating grid 19 and plate 12. Its operating characteristics are special since the cathode current is constant, the current through aperture 17 is determined by the limiter grid bias, and the plate current is prescribed by the gating grid bias. Thus the entire cathode current goes to either the accelerator alone or to the accelerator and the plate according to the voltages on the respec-

In the operation of the circuit as a free running oscillator, the gating grid is biased above cut off.

Voltage on the limiter grid increases with the positive going cycle and electrons pass to the plate. Accelerator current decreases, and hence the tank voltage increases causing regenerative buildup of the positive half cycle until the maximum portion of the electron stream reaches the plate. The tank circuit then swings negative, the limiter grid is cut off and the entire electron stream goes to the accelerator until the accelerator voltage reaches a maximum. Feedback is

thus maintained constant. The cycle repeats when the tank swings positive.

Frequency division is achieved by tuning the tank to f/N where N is a multiple of 2 and f is the frequency of the synchronizing voltage. The synchronizing signal drives the gating grid about cut off f-times per second. The tank and the limiter grid, however, swing negative each even multiple of f so that the tank locks to an even division of f.

#### Signal Attenuator

Patent No. 2,835,867. Daniel Golden. (Assigned to Underwood Corp.)

Crystal diodes such as 1N34s are used in series or in parallel or in series-parallel combination to attenuate pulse signals which exceed the constant resistance range of the crystals. For the attenuator shown, voltages in excess of  $\pm 10$  my are attenuated in an inexpensive and effective manner.

The resistance characteristics of crystal diodes prescribe decreasing resistance with increasing positive applied voltage and rapidly increasing resistance as negative voltage increases.

1958

An increase in voltage beyond the redetermined level causes the resistance one of the series diodes to increase after than the resistance of the other iode decreases. In effect, the series ciruit shows higher resistance and therese attenuation of the input. As the input voltage increases further, the resistance of one of the shunt diodes decreases and the resultant parallel resistance decreases to cause additional attenuation of the applied voltage.

OUTPUT

igh Fidelity Audio Amplifier

stent No. 2,828,369. Alpha M. Wiggins.
Assigned to Electro-Voice, Inc.)

An amplifier output stage is designed operate as a high fidelity push-pull utput having unity coupling between tubes, a low impedance output trans-

former and full drive of the entire load by each tube. As a result, the amplifier may be operated Class AB or B with negligible distortion due to transients.

Plate supply of each tube is returned to the cathode of the other tube. Two power supplies obviously are required but the advantages of the circuit are likewise evident. Thus each tube looks into the total load impedance between the cathodes of the tubes as contrasted to one fourth of the total load impedance in a conventional push-pull circuit. Unity of coupling results thus obviating transient switch distortion. The lower impedance required enables the use of a transformer having fewer windings. This produces lower distributed capacitance and, therefore, better frequency response.

#### **COAXIAL TRANSMISSION LINES and COMPONENTS**

Here is a new high in rigid coaxial transmission line efficiency and performance! Now Prodelin has applied its field-proved, reactance-compensated teflon pin insulator support within aluminum outer conductors.

within aluminum outer conductors.

This service-tested construction technique provides constant broadband impedance characteristics consistent with high power handling capability and low VSWR... and aluminum offers strength, corrosion-resistance, lightweight, and handling ease.

VHF SERIES "700" teflon pin supported inner conductor
UHF SERIES "900" service tested reactance compensated
inner conductor support

Both series lines are available in the %", 1%", 3%", 6%" and 10" sizes, 50 and 75 ohm impedances. EIA (RETMA) flanges are available.

#### FOR MILITARY AND COMMERCIAL SERVICES

# **Determining Multi-Pin** Connector Voltage Ratings

William B. Schwartz Continental Connector Corp. Woodside, N. Y.

WHEN DESIGNING electrical connectors for altitude applications it is necessary to establish breakdown voltage at decreased atmospheric pressures. The values shown in the accompanying conversion chart are in accordance with standard multi-pin connector practice (MIL-C-8384A) in which test voltage is equal to three times the working voltage and 75 per cent of the breakdown volt-

Where one parameter is known, such as a required working voltage, the resultant breakdown and test voltage may be determined. The ratings normally supplied by the connector component manufacturer represent the actual air gap breakdown voltage between unprotected contact solder terminals. This rating is useful in fixing a test voltage for component inspection purposes. However, in actual practice increased working voltage results when insulation or potting compound is used between terminals.

Conversion chart values represent reduction in dielectric strength for dry, dust-free air with respect to altitude in thousands of feet above sea level. It should be remembered that the figures shown correspond to cool gaps with only normal ionization. Values can be changed considerably by heating of the air gap during operation of contacts. According to "Paschen's law," the dielectric breakdown voltage for air is a product of pressure and electrode spacing. Regardless of reduced atmospheric pressure or contact spacing, it is impossible to cause break-

down to occur between contacts in air at voltages under 350 v. This minimum breakdown voltage is due primarily to the potential required for ionization of air to occur.

This chart is useful in determining component voltage rating based on a known or estimated breakdown voltage at sea level and at reduced pressure. altitude conditions. When the working voltage is known, the resultant breakdown voltage and required test voltage may be determined. All values are based on sea level ambient conditions. (50-60 per cent relative humidity.)

Example 1. Determine the ratings at 50,000 ft. where the breakdown voltage is found to be 4000 v rms at sea level conditions.

Solution. (a) Locate 4000 v breakdown voltage on sea level reference line (Fig. 1). Read up to test voltage 3000 v and down to working voltage 1000 v. (b) Locate 4000 v breakdown voltage on 50,000 ft. altitude line. Follow down to sea level reference line and convert as in (a) to breakdown voltage 900 v, test voltage 675 v and working voltage 225 v.

Example 2. Determine breakdown voltage and the required test voltage at sea level which will yield a 250 v working voltage for 60,000 ft. operation.

Solution. (a) Locate 250 working voltage (Fig. 2). Read chart up to 60,000 ft. intersection and across to voltage breakdown 5500 v. (b) Convert breakdown voltage 5500 v to test voltage 4125 v at sea level conditions.

THE 1802 HYDROGEN THYRATRON, WITH UNPRECEDENTED PERFORMANCE AND RUGGEDNESS, CERAMIC-ENVELOPED AND FAR SMALLER

The new EG&G Hydrogen Thyratron, Model 1802, delivers 30 megawatts peak power in a smaller package than any comparable unit. It supersedes many older types, and surpasses the performance of the Type 5948/1754 on all counts, in less than 1/7th the size. The new 1802 is air cooled by convection and will tolerate ambient temperatures up to 100° C. Yet its warm-up time is only 5 minutes. Other comparisons with the 5948/1754.

	1802	5948/1754
Input trigger power	250 v at 400 ohms max.	650 v at 250 ohms max.
Delay time	0.5 μs rated (average is 0.25 μs)	1 μs
Jitter	.002 to .005 µs	.02 µs
Reservoir Range	$\pm 10\%$	± 5%
Filament Power	90 watts	200 watts
Ambient Temp. Max.	100° C	75° C

The hydrogen thyratron was invented by K. J. Germeshausen, President of EG&G. Advanced research continues to keep this company in the forefront of hydrogen thyratron development. For specific data on the 1802, and for the most authoritative information on gas-discharge tube types and MILLI-MIKE\* CRT's, TW oscilloscopes and systems, write to us on your company letterhead.

RCA RELAYS

350 SUBMINIATURE TYPES

4 and 6 Pole AC, DC and Dry Circuits

Meet and exceed MIL-R-5757A, B, C and MIL-R-25018 (USAF)!

RCA Subminiature Relays are designed to give maximum reliability and superior performance in missile and airborne applications, as well as critical industrial uses.

More than 350 types are now available to meet the most stringent requirements—exceeding MIL-R-5757A, B, C and MIL-R-25018 USAF specifications.

RCA Relays are sold through leading electronic component manufacturers' representatives located conveniently throughout the country.

Every RCA Relay is precision assembled and incorporates these important construction features!

- Dependable stepped headers on 4 and 6 pole units for greater ease in wiring and inspection.
- Precision balanced rotary motors for high resistance to shock and vibration.
- "Getters," an original RCA development for lower contact resistance, longer life.
- Simultaneous switching of full rated loads and dry circuits.
- Special contact ratings for special purposes.
- Plug-in types in 4 and 6 pole units,
   AC, DC and Dry Circuits.
- Teflon\* Splatter Shields for positive protection against shorting of contacts.
- \*Registered trademark of E. I. Du Pont De Nemours

Send for free copy of 12 page brochure on RCA Subminiature Relays. Includes specifications, type and rating, socket, heater and enclosure diagrams.

# Simplified Rack and Panel Mounting

can be handsome, too

HE STANDARD method of attaching a panel in an instrument case involves screws through the panel to lugs within the periphery of the case. This usually results in poor front panel appearance, inaccurate fit, and awkward panel and chassis removal. Fig. 1 shows a scheme which avoids these problems and eliminates the unsightly gaps which allow dust and water to get into the chassis.

The panel and chassis are bolted together with screws which are invisible when the knobs and dials are in place. A casting, which forms the front of the unit, and requires no costly machining, covers the panel to case gap.

The unit, consisting of the panel, chassis, and casting is secured to the back of the case with two fast-lead screws. A strip of aluminum, spotwelded to the inside of the case, and protruding from its outside edge, locates the edge of the casting exactly with reference to the case by engaging in a slot in the casting. As the locating screws are tightened, the casting, front panel and chassis are firmly pulled into place. The package is completely dust-proof and can be water-proofed easily.

The unit is easily adapted for rack mounting. In this case a rack mounting adapter panel is clamped between the front casting and the instrument case, and held by the fast-lead screws at the back of the case.

Kenneth Ricketts, Southwestern Industrial Electronics Co., Houston, Texas.

1958

Many circuit applications require a single DPDT chopper rather than two SPDT choppers to obtain exact synchronism between the two chopper poles. Here's a circuit that can be used to check both poles simultaneously for phase lag, balance, dwell time, and tracking. The circuit is also useful for matching characteristics in SPDT choppers.

With tracking defined as the difference in phase lag between two switch sections, one can measure it to within one degree.

The circuit shown is simple and easy to assemble. The chopper coil voltage is fed to an RC phase shift network. The coil voltage is sent to the scope X plates and the 90 deg shifted

Fig. 1. This simple circuit can check the tracking of DPDT choppers or it can compare the operation of two SPDT units.

voltage to the Y plates. A second circle is created by periodically reducing the voltage to these plates using an auxiliary SPDT chopper operating at a frequency other than that applied to the DPDT chopper under test.

The "phase control" adjusts the circle for roundness. An additional SPDT chopper, operating at the same frequency as the first SPDT chopper, alternately inserts each section of the DPDT chopper into the blanking circuit. Whenever the contacts of the DPDT chopper open, the trace is blanked. The inner circle represents one set of contacts, while the outer circle represents the other.

Warren E. Hodges, Project Engineer, The Bristol Company, Waterbury, Conn.

#### REPORT BRIEFS

#### **Adiabatic Magnetization**

A study has been made of the adiabatic suppression of super conductivity by the application of a magnetic field. The effects of specimen geometry, rate of magnetization, and departures from the isentropic magnetization path were studied. The excessive heating accompanying adiabatic magnetization was found to arise from thermal effects along the magnetization path associated with hysteresis in the magnetization path. When these hysteresis effects are included in calculations of expected values of cooling good agreement with experimentally observed values is achieved. The exact nature of the hysteresis effect is unknown. Unless control of this irreversibility is possible, the cooling of a superconductor by adiabatic magnetization cannot be utilized effectively for refrigeration nor for producing temperatures much below one degree Kelvin. Traversal of the Intermediate State of a Superconductor by Adiabatic Magnetization, by R. L. Dolecek, U. S. Naval Research Laboratory. Jan. 1958, 19 pages, graphs, table, \$0.50. Order PB 131485 from OTS, U.S. Department of Commerce, Washington 25, D. C.

## PFM Response of Single Tuned Parallel Circuit

The steady state expression of the voltage across a single tuned parallel circuit fed by a current source possessing periodic pulse frequency modulation is computed in the case of relative frequency deviation less than or equal to one. The corresponding envelope and instantaneous frequency are derived and plotted for certain numerical examples. Presented to a conference at the Symposium "La Theorie et la Technique des Impulsions," Paris, France, Oct. 1953. Steady State Response of a Single Tuned Parallel Circuit to a Sinusoidal Current Source with Periodic Pulse Frequency Modulation, by E. Weber, Polytechnic Institute of Brooklyn, Microwave Research Institute, Brooklyn, N.Y. Apr. 1955, 35 pages, diagrams, graphs, microfilm \$3.00, photocopy \$6.30. # Nonlinear and Parametric

Phenomena

In

# Radio Engineering

A. A. Kharkevich
Translated by J. George Adashko

Part 1

We, at Electronic Design, are pleased to present, for the first time, a complete book translation in serial form. Unlike most of our "Russian Translations" this book is not intended to reveal the "state of the art" in the USSR.

It is an excellent and lucid introduction to an important aspect of electronic design—too long neglected by many American design engineers. It is brief, unified, and unexcelled in its clarity.

The Russians are past masters in nonlinear theory. Of American books on the subject, there are but four—three of which have appeared in the last few months. None have been written for the practicing electronic design engineer.

We believe that our translation of "Nonlinear and Parametric Phenomena in Radio Engineering" will provide a genuine service—not for the theorist, nor the mathematician, but for the practicing electronics design engineer.

—The Editors

Prof. A. A. Kharkevich was born in 1904 in Leningrad. He graduated from the Leningrad Electrotechnical Institute in 1930. A doctor of technical sciences since 1938, Prof. Kharkevich became a corresponding member of the Ukrainian Academy of Sciences in 1948. At present he holds a chair as professor of theoretical radio engineering at the Moscow Electrotechnical Institute of Communication. He is Director of the Communication Laboratory of the Academy of Sciences of the USSR.

Prof. Kharkevich's book **Nonlinear and Parametric Phenomena in Radio Engineering**, is the third part of a textbook, the first two parts of which were published under the title *Theoretical Principles* of *Radio-Communications* (State Publishing House of Technical and Theoretical Literature, Moscow, 1957).

#### **Translator's Foreword**

For every electronic engineer exposed to a course on nonlinear mathematics or nonlinear circuit theory, there must be at least a dozen, whose knowledge of the subject does not go beyond the B-H curve, drawing a load line, or calculating harmonic distortion. Yet almost all electronic functions—rectification, oscillation, detection, and so on—are inherently nonlinear. A possible exception is amplification, and even there the linearity is more formal than actual.

There is good reason for this—the principle of superposition. As long as the electronic art was more interested in the circuit aspects, the powerful tools based on this principle (e.g., Thevenin's or the reciprocity theorem, Laplace or Fourier transforms) could not be given up readily, and the various linearization techniques were preferable to "pure" nonlinear analysis.

It seems inevitable, however, that electronics is doomed to leave the straight though not narrow path of linearity (to pitch a wild curve at the metaphor). In the case of transistors, for instance, the old work horse, the equivalent circuit, is frequently quite hard pressed to provide a satisfactory theory, even in the first approximation. It is most likely that twenty five years from now the electronic engineers will wonder how their parents managed to do without a knowledge of Poincaré's theory, just as we marvel how it was possible to get through the EE course in 1933 without a knowledge of Maxwell's equations.

Russian work on nonlinear theory dates back to Liapunov's "Problème Général de la Stabilité du Mouvement" of 1892, but serious work began in the early thirties. The results are not our primary concern here; suffice it to point out that Andronov and Chaikin's "Theory of Oscillations" (Princeton, 1949) and Krylov and Bogoliubov's "Introduction to Nonlinear Mechanics" (Princeton, 1943) are among the most frequently referred-to books when it comes to nonlinear theory.

It is little wonder, therefore, to those who have been following our abstracts in "What the Russians are Writing," that articles on nonlinear circuits or methods appear frequently in Russian electronic literature. There are several books exclusively devoted to "Nonlinear Radio Engineering," one of which is Prof. A. A. Kharkevich's monograph "Nonlinear and Parametric Phenomena in Radio Engineering." It is a brief and clear theoretical introduction to the subject, written for practicing engineers. Your translator liked it, your editors liked it—we hope you like it, too.—

J.G.A.

#### **Author's Introduction**

#### 1. Scope of the subject

This book is devoted to nonlinear and parametric phenomena in radio engineering.

The term "nonlinear" pertains to the physical features of the studied phenomena, features reflected in the mathematical equations for the behavior of various radio engineering elements.

In radio engineering we deal with phenomena that can be described by mathematical equations of the following three types:

1. Linear equations with constant coefficients.

2. Linear equations with variable coefficients.

3. Nonlinear equations.

These three types are quite dissimilar in their properties and must be solved by entirely different methods; hence the traditional division into "linear" and "nonlinear" approaches to radio engineering.

Linear equations with constant coefficients are the simplest type. Their theory has been developed in detail and powerful general methods exist for their solution (for example the Fourier and Duhamel integral methods). These general methods are based on the superposition principle whose applicability serves as a definition of a linear system, i.e., of a system described by linear equations with either constant or variable coefficients.

The general form of a homogeneous linear equation with constant coefficients is

$$a_n \frac{d^n y}{dt^n} + a_{n-1} \frac{d^{n-1} y}{dt^{n-1}} + \ldots + a_1 \frac{dy}{dt} + a_0 y = 0,$$

where  $a_n, a_{n-1}, \ldots, a_1, a_0$  are constants.

A characteristic of linear equations with variable coefficients is that the coefficients depend on the argument t, i.e., they are specified functions of time. The theory of such equations is more complicated and less fully developed. This is why phenomena described by equations with variable coefficients are frequently classified as "nonlinear."

From the physical point of view, equations with variable coefficients describe the behavior of systems with parameters that vary with time in some manner. Such systems, and the phenomena that take place in them will be called *parametric*. Examples of equations with variable coefficients are

$$\frac{d^2y}{dt^2} + ty = 0,$$

$$\frac{d^2y}{dt^2} + (a + 2q\cos 2t) y = 0.$$

are available from stock. The "Detent" model locks in 7 tilt positions. The "Basic" model tilts with no lock assembly. The "EZ Mount" model tilts from mounting on front cabinet rail. These models are available in either lightweight or heavy-duty styles.

Chassis-Trak slides, formed from cold rolled-steel, give complete accessibility and faster servicing... and the ultra-thin design means you can cut engineering costs by mounting 17" chassis in 19" standard stock racks. Plus, a wide bearing area design increases rigidity and reduces the possibility of binding due to misalignment.

In addition to the standard slides in stock, Chassis-Trak engineers will custom-build slides for special installations. All slides meet specifications for government or military projects and RETMA standards.

The latter equation is called the Mathieu equation and plays a very important role in radio engineering.

Finally, nonlinear equations are distinguished in that their coefficients depend on the *function* or on its derivatives. This type of equation is the most difficult to solve. Several general methods will be considered as applied to various radio engineering problems.

Examples of nonlinear equations are

$$\frac{d^2y}{dt^2} + ay^2 = 0, \qquad \frac{d^2y}{dt^2} + \frac{dy}{dt} y = 0,$$
$$\frac{d^2y}{dt^2} + f\left(\frac{dy}{dt}\right) + y = 0.$$

The last equation is quite general; it is encountered in the theory of vacuum tube oscillators.

#### **Mathematical Analysis**

We are interested in the mathematical aspects of this subject because mathematical analysis permits a quantitative investigation of various types of electronic apparatus and, in the final analysis, provides us with a design procedure.

As to the physical and engineering aspects of the subject, it must be mentioned that some of most important phenomena and processes used in radio engineering—oscillation, frequency multiplication and division, rectification and detection, modulation, and frequency conversion are nonlinear or parametric.

They are describable by nonlinear equations or equations with variable coefficients. These equations indeed constitute the mathematical formalism of "nonlinear" radio engineering.

#### 2. Methods of Nonlinear Theory

The principle of the superposition, which is the basis of linear theory, cannot be used for the investigation of phenomena in nonlinear systems.

Let us explain this statement briefly by starting with a linear system, describable by the linear algebraic equation y = ax.

Here x and y are functions of time, x being the input to the system and y the output. The principle of superposition says that if the input to the system is  $x = x_1 + x_2$ , the output will be

$$y = ax = a(x_1 + x_2) = y_1 + y_2,$$

i.e., the two components  $x_1$  and  $x_2$  act independently. Thus, the current resulting from several voltages in a linear system is the sum of the cur-

rents produced by each voltage separately, in the absence of the others.

The principle of superposition is the basis of all general methods for solving many lineartheory problems. We are so used to constant application of this principle, that we must be especially reminded that this principle cannot be employed for nonlinear problems without causing serious errors.

Let us illustrate this with a simple example. Suppose we have a nonlinear, say quadratic, equation.  $y = ax^2$ .

Let furthermore

$$x=x_1+x_2.$$

Then

$$y_1 = ax_1^2, \quad y_2 = ax_2^2.$$

But

 $y = a(x_1 + x_2)^2 = ax_1^2 + ax_2^2 + 2ax_1x_2 = y_1 \times y_2$ , i.e., the square of the sum does not equal the sum of the square.

Therefore, for example, when several voltages act on a nonlinear circuit, one can no longer reduce the solution of the problem to the summation of currents due to each individual voltage. It is necessary to take into account all the voltage components simultaneously.

The situation becomes more complicated when we go from nonlinear algebraic to nonlinear differential equations.

#### **Specialized Methods**

The fact that we are forced to forego the principle of superposition causes us to lose many possible solution techniques. Unfortunately, such powerful and universal methods as are available to linear theory are still missing from nonlinear theory. A worker in the nonlinear field has at his disposal a variety of specialized methods and artifices, each of varying effectiveness and of differing range of applicability. We shall describe these methods briefly, for the moment; later we shall become better acquainted with their applications to various problems in radio engineering.

1. The algebraic problem of finding y(t) for a specified x(t) and for a given nonlinear characteristic

$$y = f(x)$$

can always be solved graphically with any degree of accuracy desired.

2. The same problem can also be solved analytically, i.e., it is possible to find a function

$$y(t) = f[x(t)],$$

(Continued on following page)

# 4 Ounce Contact Force Gives Relay Reliability

Contact force of 4 ounces per contact on 50 "G" models and 2 ounces per contact on 30 "G" models of "Diamond H" Series R and Series S miniature, hermetically sealed, aircraft type relays is one of the most important factors in their proven high reliability.

Though absolute reliability of any similar device is impossible to guarantee—a bitter fact of life recognized by all electronic engineers—close approach to this goal by the relays manufactured by

The Hart Manufacturing Company is the basic reason they are found today on many of this country's headline-making missiles.

In addition to contact force far beyond that found on other relays, "Diamond H" relays have greater contact cleanliness. Selfcontamination is virtually eliminated by a completely inorganic switch mechanism, as well as use of coil materials which will not dust, flake or out-gas.

Finally, the high degree of reliability that is designed into these relays is maintained in their manufacture by high quality workmanship and a stringent inspection policy at every stage.

In addition to missiles, and their ground control systems, Series R and S relays are designed for use in jet engine controls, computers, fire control, radar and similar critical applications.

4PDT units, they offer an extremely broad range of performance characteristics, including temperature ranges from —65° C. to 125° and 200° C.; ratings to 10 A., 120 V., A. C., and 26½ V., D. C., with special ratings to 400 ma. at 350 V., D. C., or down to millivolts and milliamperes. Dry and wet circuits may be safely intermixed.

For more information, write today for Bulletins R250 and S260. For quick facts about "Diamond H" switches, thermostats and other devices, ask also for a copy of the "Diamond H" Check List of Reliable Controls.

provided an analytic expression is available for the characteristic of the system

$$y = f(x)$$
.

Under these conditions it is usually possible to solve differential equations.

3. In must be noted that the characteristic of the system is quite frequently known from experiment, i.e., it is given in the form of a graph or tabulated data. The determination of an analytic expression, representing the actual relation with sufficient accuracy, is thus a very important operation in nonlinear theory. This operation is called the *approximation* of the nonlinear characteristic.

The approximation should, as far as possible, satisfy the following requirements: (a) The analytical expression should represent the approximated relation with sufficient accuracy, (b) it should be amenable to the performance of various required mathematical operations, and (c) it should be as short and simple as possible.

Unfortunately, the existing approximation methods do not satisfy these requirements to an equal extent. The following principal methods are used: (a) approximation by a polynomial, (b) approximation by a broken line, (c) approximation by transcendental functions.

The first methods consist of representing the function y = f(x) in the form

$$y = a_0 + a_1x + a_2x^2 + \ldots + a_nx^n = \sum_{k=0}^n a_kx^k,$$

The number of terms of the polynomial depends on the required accuracy. In any case, the approximation must reflect at least the fundamental qualitative features of the phenomenon. This applies naturally to all approximations.

Approximation by a broken line, also called piecewise linear approximation, consists of replacing the plot of the actual relation with linear segments, the approximation improving with the number of segments employed.

Piecewise linear approximation is particularly suitable for representing characteristics of rectifiers, tube operation at cutoff, etc. This form of approximation is interesting because it permits a special method for solving nonlinear differential equations, the so-called "joining method."

This method consists essentially of representing the behavior of the nonlinear system by different linear equations for different intervals of the values of the variable, and replacing the nonlinear characteristic by a segment of a straight line within each interval. The solutions of the various linear equations must then be "joined" on the boundaries of the intervals, i.e., the value on the end of one interval must be equated to the value on the beginning of the next interval.

ELECTRONIC DESIGN • September 17, 1958

As regards approximation by transcendental functions, for example, by exponential or hyperbolic functions, this method leads to very compact expressions, which give at the same time a very good approximation. Unfortunately the subsequent treatment of these expressions becomes quite difficult.

4. An important role is played in nonlinear radio engineering by so-called "quasi-linear" methods. In these methods the equation of the nonlinear system is replaced by an equation of linear form, but the coefficients of this latter equation are certain average parameters, determined with allowance for existing nonlinearities.

The average values of the parameters thus depend on quantities that characterize the performance of this system. Quasi-linear methods are particularly suitable for the investigation of steady-state response of nonlinear systems to nearly sinusoidal signals.

5. If we are interested in a system approaching steady-state, the quasi-linear method of slowing varying amplitudes can be used to advantage. The general idea of this method is to assume that the steady-state oscillations in the investigated apparatus have amplitudes and frequencies that vary slowly. This permits a substantial simplification in the problem. Subject to certain assumptions (which will be discussed in detail), we obtain as a rule, an equation of one order lower than the initial equation. The method of slowly-varying amplitudes is used principally in cases when it is known beforehand that the oscillation is nearly sinusoidal.

6. Perhaps the most general method is that of plotting integral curves for the given nonlinear differential equation. This is known as the *isocline method*. We note for the time being that the method permits a solution of nonlinear problems of most general character.

It is suitable for both steady-state and transient modes, both sinusoidal and pronouncedly non-sinusoidal, the so called relaxation oscillations. A convenient variant of this method, which reduces the determination of the slope of the integral curve to a purely geometrical construction, is known as the *Lienard construction*.

7. Finally, a general method, which leads (sometimes with great simplicity) to important conclusions of general physical character, is the energy method. It consists essentially of considering the energy balance of the nonlinear system, i.e., of direct application of the law of conservation of energy. This method does not always throw light on the details, but gives reliable generalizations concerning the nature of the phenomenon.

These, in brief, are the research tools which will be used henceforth.

#### **NEW PERIODICALS**

An ambitious undertaking of the Ministry of Higher Education in the USSR is the publication of 23 series of periodicals called "News of the Higher Institutions of Learning of the Ministry of Education, USSR." Those journals of interest to electronic design engineers cover radio engineering, radio physics, and instrument building. Others are devoted to mathematics, physics, electromechanics, and electric power.

We have just received the first issue of the radio engineering journal, *Izvestiya MVO-Radiotekhnika*, dated Jan.-Feb. 1958. Published by the Kiev Order of Lenin Polytechnic Institute, and intended for teaching staffs of higher scientific institutions, graduate students, and technical personnel of commercial and scientific-research institutes, it has a heavy theoretical emphasis.

ELECTRONIC DESIGN will expand its coverage to include abstracts of papers in these journals which are significant to our readers.

#### MODULATION

Use of Controlled Surface Effect for Modulation by V. S. Etkin. RE 3/58, pp 66-69, 2 figs, 1 table.

In an earlier article by the same author (Radiotekhnika i elektronika, April 1957) it was shown that in systems containing ferromagnetic conductors it is possible to obtain modulation by using the dependence of the high frequency resistance of the conductor on

its magnetic permeability (skin effect). This article is a brief summary of experimental results on this effect.

Adoption of Auto-Anode Modulation by A. I. Miroshin. RE 3/58, pp 15-20, 6 figs.

Auto-anode modulation was first developed by M. G. Kruglov in 1949. Extensive tests have been made on this method using short-wave, medium-wave, and long-wave broadcast transmitters, and the results of the tests are reported. It is recommended that this system of modulation be more extensively used.

#### **ACOUSTICS**

Investigation of an Electron-Acoustic Converter by Yu. B. Semennikov. AJ 1-3/58, pp 73-84, January-March 1958, pp 73-84.

Description of a mechanism of an electron-acoustic conversion. The fundamental relations are derived for the output signal of an electron-acoustic converter as a function of the applied sound pressure at a specified contrast of the electric image. A procedure is given for the experimental determination of the equivalent electric parameters of an electron-acoustic converter.

Possibility of Employing Maximum Amplitude Limitation of Speech Signals in Communication Systems by Yu. G. Rostovtsev. EC 6/58, pp 49-52, 5 figs.

The author gives the articulation characteristics of speech signals in the case of strong amplitude limitations. These characteristics were obtained by connecting various linear filters before

Fig. 1. Principle of the inductive linear potentiometer. The voltage across the load resistance is proportional to the angular displacement between rotary transformers I and II.

and after the limiter. It is shown that the use of a limiter of more than 40 db increases the interference immunity of the reception to such an extent, that there is a 7-10 fold gain in power.

author compares such clutches with electric motor, friction, and hydraulic devices with regard to starting time, electromagnetic time constant, control power, and ratio of output to inertia torques. The ferromagnetic clutches appear to be superior to torque motors and friction clutches. Reference is made to "Characteristic of Some Magnetic Fluid Clutch Servo Mechanisms" by Pairiale and Tilton (*Transactions AIEE*, Volume 69, Part 1, 1950).

Calculation of an Adjustable Rectifier with Allowance for the Effect of Phase Overlap by V. N. Aksenov. EC 12/57, pp 30-36, 5 figs, 1 table.

This appears to be the first attempt to analyze inductance loaded, grid-control rectifiers with allowance for the sector of phase overlap. The author gives a procedure for calculations in generalized coordinates of the characteristics, the short-circuit current, and the output ripple. Tables and graphs accompany the discussion.

Grapho-Analytic Method of Calculation of Transients in DC Electromagnetic Mechanisms by R. A. Agaronyants. EC 1/58, pp 34-42, 8 figs.

A rigorous grapho-analytical method is given for solving the dynamic equations involved in transients of moving-armature dc electromagnetic mechanisms. A solution is obtained by numerical integration. The calculations for a telephone relay are presented as an illustrative example.

Mechanism of Action of Cathode-Ray Barrier-Grid Memory Tube for Digital Computers by N. L. Yasnopol'skiy and A. P. Alekseyeva. REE 1/58, pp 142-154, 12 figs.

The fundamental factor that limits the capacity of the memory and the permissible number of addresses in memory tubes for digital computers is the parasitic seeding of neighboring elements of the dielectric target. This is primarily due to secondary electrons, in the recording, reading and recovery of signals in any element. The article gives the results of a direct experimental investigation of the seeding using a grid-barrier tube as a model. On the basis of these results, the authors analyze the processes of recording. reading, and retrieval of binary symbols in this tube. The conditions under which maximum number of addresses are obtained for a specified size of signals are indicated. The increase in the pulse for the recording of a unit obtained by changing over to mode of unbalanced recording.

Forward Scatter Radio Communication at UHF, Employing Meteoric Ionization of the Atmosphere by M. N. Arone. EC 6/58, pp 40-48, 8 figs.

A survey is given of the essential factors that determine the effectiveness of a meteor-burst system for radio communication. Formulas are given for estimates of the power of the received signal. The block diagram, operating principle, certain results of an experimental system of meteor-burst communication are considered. Reference is made to several American and Canadian articles on the subject.

Correlation of Fading in Neighboring Sections of Radio-Relay Communication Lines by Yu. B. Sindler and A. S. Nemirovskiy. RE 11/57, pp 21-28, 4 figs, 2 tables.

The factors that affect the probability of failure of radio relay lines due to fading are analyzed. Certain problems in the statistical analysis of fading in radio-relay lines with a large number of sections are given, along with data on the operation of the Moscow-Gor'kiy radio-relay line during 1954-1956.

Effect of Correlation of Scatterer Velocity on Stalistical Properties of Scattered Radiation by G. S. Gorelik, REE 10/57, pp 1227–1233, 3 figs.

The scattering of radio waves by irregularities, the velocities of which change in a stationary random manner and which are dependent on each other, is investigated. A formula is derived for the correlation functions (spectra) of the scattered field, of the components of its slowly-vary-

Specialty Brazing Laboratory, Riverside, Connecticut, brazes, among other things, a bus bar contact for Rolock, Inc., Fairfield, Connecticut, makers of fabricated metal products. While a relatively simple assembly, it points up the remarkable *fluidity* of Handy & Harman Silver Brazing Alloys.

Both assembly components are copper. Base plate dimensions are  $\frac{1}{4}$ " x  $8\frac{3}{4}$ " x  $2\frac{3}{4}$ ", and the  $\frac{1}{6}$ " thick triangular piece is 3" on its base with  $2\frac{7}{6}$ " sides.

After cleaning, the joint area of the base plate is HANDY-FLUXED and a shim of EASY-FLO 45 is placed on the base plate and the triangular piece set upon the shim. Heating by Selas gas-air burners is done on a 50-second cycle. Alloy cost is approximately

four cents per assembly.

You'll notice, in the photo of the completed assembly, how smooth the alloy fillet is. The capillary action of EASY-FLO causes it to flow out in three directions, providing even joint penetration. This single fact (without going into the qualities of strength, conductivity, corrosion resistance, etc.) makes EASY-FLO a natural for electrical applications. Handy & Harman has, readily at hand, extensive data on the advantages of silver brazed joints for electrical applications. We are always ready and happy to discuss joining requirements and techniques with you. Your call or inquiry will bring complete and beneficial details.

FIRST, BULLETIN 20

This informative booklet will get you off to a good start on the values, techniques and economies of low-temperature silver brazing. A copy awaits your request.

# WITH FAFNIR MINIATURE BALL BEARINGS YOU GET ALL FIVE IMPORTANT FEATURES

VACUUM MELT 440C. Balls and rings of Fafnir miniature bearings are made from vacuum melt 440C stainless steel.

ADVANTAGES. Since vacuum melt steel is extremely clean, balls and races are free from pits and inclusions providing better finishes which result in super sensitive bearings with low torque values.

BALANCED DESIGN. Each size bearing has its "tailor-made" retainer of predetermined weight and dimensions.

**ADVANTAGES.** Pitch circle of the balls is centered between bore and O.D. and bearing is symmetrical in design.

HARDENED RETAINERS. All retainers are made of hardened 410 stainless steel.

ADVANTAGE. Precise hardening, under rigid quality control, provides springiness without brittleness, eliminates bending or distortion.

SWAGED RETAINERS. In manufacture, retainers are swaged so that ball pockets of retainers are ironed outwardly.

ADVANTAGE. Ball runs against a hardened, smooth surface not a rough edge.

**HEAT STABILIZATION.** All rings and balls are heat stabilized to 600 degrees.

**ADVANTAGE.** Standard Fafnir bearings may be used for high temperature applications as well as regular applications.

Fafnir Miniature Bearings—part of a broad line of Fafnir bearings for instruments and precision mechanisms—are made to ABEC-7 standards except for bores where tolerances are  $\pm .0000$  —.0002 for greater flexibility in selective assembly. Balls are lapped to 2.5 millionths for sphericity and 5 millionths for size variation. Open and two-shield types, with or without flanges, are available. Write for Bulletin 469. The Fafnir Bearing Company, New Britain, Connecticut.

#### **RUSSIAN TRANSLATIONS**

ing amplitude, and of its intensity. The general relations are illustrated with the aid of a two-scale model of partially correlated motion of the scatterers. This work extends the investigation, reported by the same author in the June 1956 issue of *Radiotekhnika i Elektronika* (Page 695), dealing with the connection between the theory of scattering of radio waves by wandering irregularties and the theory of turbulent diffusion.

Medium-Wave Radio Broadcast Antenna on Low Masts by B. S. Nadenenko. RE 7/57, pp 46-55, 12 figs.

A popular article on the same subject appeared in Vestnik Svyazi for May 1957. The present article has an engineering description and various tuning schemes of a slot-type medium-wave antenna, and details a method for the analysis of all the parameters of the antenna.

Limiting Accuracy of Long Range Radar System by G. A. Zuykina. RE 12/57, pp 19-20, 2 figs, 1 table.

The author discusses the effect of propagation conditions on the phase and phase velocity of radio waves in the 100-150 kc band. Results of calculation of correction for phase and phase velocity for the various types of grounds are given. Plots are given for the phase velocity as a function of the ground properties. An estimate is made of the limiting accuracy of long range radar with a phase measurement, as affected by a ground surface.

Calculation of Gain of Periscopic Antenna Systems by A. M. Pokras. RE 11/57, pp 13-20, 5 figs.

Modern periscopic systems can be subdivided into two classes: systems with parabolic radiators, and those with ellipsoidal radiators. Each class can be subdivided into two subclasses, with either plane or parabolic reflectors. Formulas and universal graphs for the gain of a periscopic system with an ellipsoidal mirror radiator, having either a round or square aperture, are derived. Systems with plane and parabolic reflectors are also considered. Refers to an article by E. Bedrosian, Transactions IRE, page 168, 173, October 1955.

Investigation of Upper Layers of the Atmosphere by L. Karyakin. R 12/57, pp 19-20.

Brief popular discussion of the effect of various ionized layers on the propagation of radio waves.

#### **MEASUREMENTS**

Determination of the Error in the Constancy of the Phase Difference Over a Frequency Band by N. Vinogradov. EC 5/58, pp 35-43, 13 figs.

It is required to obtain, in a certain frequency and, constant phase difference between the output voltages of networks I and II in Fig. 3. Errors in the constancy of the phase will rise because of the inexact matching of the wave impedances of the networks to the load impedances. Measures of eliminating these errors are indicated in the article.

Contactless Method of Determining Specific Electric Resistivity by G. G. Yarmol'chuk, AT 3/58, pp 257-267, 10 figs.

Description of a method for measuring specific resistivity. The method is based on the use of high frequency currents induced in a conducting body placed in an alternating magnetic field. The equivalent circuit of the tested body is first developed, and a bridge method is designed for the measurements. In addition, the use of this method for quality control of carbon brushes is described. Reference is made "Now a Useful Nondestructive Testing Tool" by H. Staats Materials and Methods, Volume 38, No. 4, 1953) and "Eddy Current Testing" by R. Hochschild (Control Engineering, October 1954).

#### **TELEMETRY**

Telemetering System With Pulse-Code Modulation by G. V. Burdenkov. AT 1/58, pp 55-63, 11

Examination of a high speed pulse-code telemetering system. It is shown that it is possible to synthesize telemetering systems using magnetic elements with rectangular hysteresis loops in conjunction with transistors and crystal diodes. The fundamental parameters of the equipment are given and an estimate of the telemetering accuracy is made. Refers to "Oxford Pulse-Code Modulation System" (Proceedings IEE, Volume 41, No. 7, 1953), "Coding by Feedback Methods" Proceedings IEE, Volume 41, No. 8, 1951).

#### **RUSSIAN TRANSLATIONS**

Optimum Frequency Deviation in a Single-Channel Telemetering System by Yu. I. Chugin. AT 4/58, pp 346-364, 6 figs.

The author shows that it is possible to obtain, for telemetering systems with idealized receiver characteristics, an analytic expression for the optimum deviation. The computation method is based on an analysis of the noise in the energy spectrum. Standard methods of the theory of random functions are used. Reference is made to "Statistical Properties of Sign-Wave Plus Random Noise" by S. O. Rice (Bell System Technical Journal, Volume 27, No. 1, 1948) and "The spectrum of Frequency Modulated Waves After Reception in Random Noise" by D. Middleton (Quarterly of Applied Mathematics, Volume 7, No. 2, 1949).

Telemetering Balanced Device For the Measurement of Linear Displacements by A. A. Kol'tsov and L. F. Kulikovskiy, AT 3/58, pp 280-284, 7 figs.

Description of an inductive follow-up system for linear displacements, suitable for automation and remote control. A theoretical analysis and construction data of the system are given. The transducers are essentially closed magnetic circuits having one coil, in which the induced voltage is proportional to the linear displacement.

#### **AUTOMATIC CONTROL**

Optimum Transients in an Automatic Control System with a Limited Regulator Position by Ye. K. Krug and O. M. Minina: AT 1/58, pp 10-25, 13 figs, 3 tables.

Optimum transients are determined for control systems that contain objects with different dynamic characteristics, including delay elements, in which the regulator has limited positions. It is shown that it is quite difficult to realize optimum transients in a control system by using continuous-action regulators, since the characteristics of the nonlinear converters of these regulators depend on the magnitude and position of the disturbances and on the initial values of the limited coordinates. It is proposed to employ a discrete regulator for the production of the optimum transients. Reference is made to "Predictor Servomechanisms" by L. Silva (Transactions IRE, March 1954).

Concerning the Synthesis of Linear Dynamic Systems with Variable Parameters by A. M. Batkov. AT 1/58, pp 49-54.

A method is developed for determining the differential equations of a linear dynamic system with variable parameters from a specified pulse

#### Cambion® Battery Holders Hold Tight

CAMBION silver-plated battery holders are designed to grip mercury batteries under severe service conditions. Compact and easy to mount, they are ideal for use in transistorized circuits, printed or otherwise.

Five types are available, accommodating

mercury cells with a .655" nominal diameter. 2233 and 2234 accommodate one or two cell mercury batteries and mount simply with only two rivets or eyelets. Three holders new to the CAMBION line are 2475, 2477, and 2324, to handle three, four, and five cell batteries respectively, and all mount directly to the chassis or printed circuit board. A unique spring-loaded end accommodates the production tolerances of the mercury cell and allows insertion of the cell in tight spots no longer than the holder itself.

All five Cambion holders feature a positive, low resistance contact. Carefully processed from phosphor bronze and finished with .0003" silver plate, they are corrosion-proof even under battery leakage.

If you have battery-securing problems, get the complete specifications for these CAMBION battery holders. Write to Cambridge Thermionic Corporation, 457 Concord Avenue, Cambridge 38, Massachusetts.

transfer function. Reference is made to "Frequency Analysis of Variable Networks" by L. A. Zadeh (*IRE*, Volume 38, No. 3, March 1950) and "Properties of Impulse Responses and Green's Functions" by K. S. Miller (*IRE Transactions on Circuit Theory*, Volume CT-2, 1955).

Frequency Methods of Remote Control of Distributed Objects by V. A. Il'yin and K. P. Kurdyukov. AT 2/58, pp 174-186, 12 figs, 1 table.

The problems involved in the remote control of many small objects (rather than large concentrated objects) are quite different. For example, it is not so much a problem of signal to noise ratio or load capacity of the system (both are high in distributed systems), but a question of reliability of apparatus at unattended points of the system and the simplicity of the system as a whole. The author shows that the frequency method of selecting and controlling distributed objects, using a wire transmission channel, is preferable for such service. The construction of remote control devices, including frequency relays with series tuned circuits, is considered.

Increase of Speed of Certain Automatic Control Systems with the Aid of Nonlinear and Computing Devices by G. M. Ostrovskiy. AT 3/58, pp 208-216, 3 figs.

The problem of introducing nonlinear devices into certain automatic control systems for improving the quality of regulation are discussed. The analysis of a third order control system (one with derivative and acceleration feedback) is analyzed as an example.

#### **ELECTRON PHYSICS**

Concerning the Drift Velocity Method by Yu. N. Obraztsov. Journal of Technical Physics. 2/58, pp 245-249.

The author considers the causes of the apparent discrepancy between the results of calculating the current density by strict solution of the Boltzmann equation and by using the drift-velocity method in the case when the mean free path time depends on the velocity. A correctly performed calculation by the drift-velocity method leads in this case to the correct results. This topic was also treated recently by R. B. Dingle (*Physica*, Vol. 22, page 671, 1956).

Volume Peltier Effect in Germanium by P. I. Baranskiy. Journal of Technical Physics (Zhurnal Tekhnicheskoy Fiziki), 2/58, pp 225-230, 6 figs.

first attempt in an investigation of the volume Peltier effect, which develops at irregularities in the specific resistivity of germanium single crystals. The experimental results show that the Peltier effect is proportional to the current.

Equilibrium Distribution of the Potential, Field, and Carrier Concentration on Fused-In Junctions by E. I. Adirovich, Yu. S. Ryabinkin, and K. V. Temko. Journal of Technical Physics (Zhurnal Teknicheskoy Fiziki), 1/58, pp 55-66, 9 figs.

The authors show that, except in special cases, the thermodynamic equilibrium distribution of the potential, field, and carrier concentration cannot be solved in general by the Shockley method (*Bell System Technical Journal*, Vol. 28, pages 435, 1949). One cannot neglect the concentrations of the electrons and holes in the junction region compared with the concentration of the dominating impurities, and proceed to give a mathematical formulation and a general solution to the problem.

Propagation of Electromagnetic Waves in Decelerating Systems Employing a Helix and a Dielectric by B. M. Bulgakov and V. P. Shestopalov. Journal of Technical Physics (Zhurnal Tekhnicheskoy Fiziki), 1/58, pp 188-201, 7 figs, 3 tables.

The article considers the propagation of electromagnetic waves in a helix, placed in a dielectric medium, in the presence of an electron beam. It also considers the properties of decelerating system, in which it is possible to vary structurally both the helix as well as the dielectric. This article covers much of the ground that is covered also in a similar article by one of the authors (Shestopalov) in the January 1958 issue of *Radiotekhnika i Elektronika*.

Preliminary Results of Nonlinear Theory of Self-Oscillations of Backward Wave Tube with Longitudinal Field by G. N. Rapoport. RE 2/58, pp 249-254, 4 figs.

The nonlinear equations of a type O backward wave tube are formulated for the case of small space charges and small damping. The analysis of the solution is used to consider the bunching of the electrons in the backward wave tube and the causes that reduce the effectiveness of a backward-wave oscillator compared with that of an ordinary traveling wave oscillator. The dependence of the power on the oscillator parameters and the maximum efficiency are calculated. Refers to work by Johnson (*Proceedings*

Calculation of the Dependence of the Current Gain Coefficient on the Emitter Current in Alloy Type Germanium Transistors for Injection and Extraction at High Temperatures by L. L. Makovskiy. Journal of Technical Physics (Zhurnal Tekhnicheskoy Fiziki), 1/58, pp 52-54, 1 fig.

A theoretical explanation is given for the experimental results reported previously in this journal. The explanation is based on work by W. M. Webster, *Proceedings IRE*, Vol. 42, No. 5, 1954. Reference is also made to work by R. N. Hall, *Proceedings IRE*, Vol. 40, No. 11, 1952.

Nonlinear Semiconductor Impedance, Sensitive to Magnetic Fields by G. Ye. Pikus and O. V. Sorakin. AT 2/58, pp 187-188, 1 fig.

A useful property of nonlinear resistances is that the sign of the change in resistance depends on the directions of the electric and magnetic fields. Since the dimensions of the individual resistances are small, a block of such resistances, assembled and oriented in a suitable manner, can be placed as a whole in the gap of a single permanent magnet.

#### RADAR

Influence of Fluctuations On the Operation of an Automatic Range Finder by I. N. Amiantov and V. I. Tikhanov. AT 4/58, pp 325-333, 6 figs.

The article considers the operation of the simplest type of range finder used in automatic tracking systems, in the presence of fairly small fluctuations and a stationary target. Straightforward statistical theory is employed.

#### RELIABILITY

Increase of the Reliability of Systems with Spares by B. R. Levin. EC 11/57, pp 65-72, 6 figs.

The reliability of a system with many elements has been studied by many investigators. This article is devoted to methods of increasing reliability by introducing spare elements. One of the fundamental assumptions that any two elements of the system are independent, i.e., that when one element goes out of order it does not affect the reliability of the second element. Reference is made to work by Moskowitz and McLean "Some Reliability Aspects of System Design" IRE Transactions, PGRQC-8, September 1956.

CIRCLE 382 ON READER-SERVICE CARD

This new portable multimeter incorporates a new technique that protects both meter and entire internal circuit against accidental burn-outs. In fact, any high voltage or current may be applied directly across any function, including ohms, without danger to the meter movement or associated components. Has a sensitivity of 20,000 ohms per volt DC or AC. Has 6-inch meter and full-wave bridge type \$66.50 rectifier circuit. Test leads are included.

#### REGOHM SOLVES Another Electronics Control Problem

# REGOHM REGULATOR MAINTAINS CRITICAL 0.05% ELECTRONIC EMISSION IN DIATRON CIRCUIT

"The final design was made possible by the Electric Regulator Corporation's ten step contact finger regulator . . ."

That is the tribute paid to REGOHM'S multi-contact voltage control by Consolidated Electrodynamics' engineers in speaking of their Type 24-210 Leak Detector.

The REGOHM regulator is used to provide an accurately controlled voltage to the tungsten filament in the Diatron mass spectrometer tube. It is this filament that produces the electron bombardment of the sampled gases passing through a magnetic field—causing each gas ion to assume a distinctly different path. This selective action affords the means for detection, and quantitative measurement, of the specific gas concerned.

Tests with other regulating devices, such as thyratrons or mercury-wetted contact relays, were unsatisfactory — either because of poor performance or excessive costs.

The following distinct advantages were acclaimed for REGOHM by Consolidated Electrodynamics...

- 1. The enormous power gain provided through flat compounding; the current needed to operate all ten contacts being only 5% more than that required for the first stage.
- 2. Relatively low power dissipation in the parallel resistors in ratio to the power fed into the filament.
- 3. Adjustable dashpot to check oscillation tendency in the circuit.
- 4. A compensating relay by-pass provision for holding voltage in the regulator tube when relays are open to prevent destructive surging when filament is switched on.

The REGOHM'S unique combination of advantages—flexibility, plug-in design, compact size, outstanding reliability, and low cost—is providing the answer to difficult regulation problems in many types of circuit. Why not consult our engineering staff to see how well it can fit your application? Please contact Electric Regulator Corporation, Norwalk, Connecticut.

# Analog Solution of Mathieu Equations

THE PRINCIPLE of frequency division by use of mixers with feedback can be used to construct electronic circuits which solve Mathieu's, Hill's and similar linear differential equations with variable coefficients. Such equations describe physical systems with parametric excitations and serve as "auxiliary" equations to determine the stability of solutions of many nonlinear systems.

Frequency division by use of feedback-controlled mixers is illustrated schematically in Fig. 1. Assume a signal of frequency  $f_o$  at the output is fed to a nonlinear circuit in the feedback loop so that harmonics are generated. A filter selects the kth harmonic,  $kf_o$ . In the mixer the frequency  $f_i$  is mixed with  $kf_o$  and a beat frequency is filtered out. Hence, the frequency at the output,  $f_o$ , is an exact submultiple of the input frequency and may be represented by

 $f_o/f_i = 1/(1 \pm k)$ 

For the case k = 1,  $f_o/f_i = 1/2$  and the feedback channel is simplified as shown in Fig. 2 since

Fig. 1. Frequency divider using a feedback-controlled mixer.

Fig. 2. Schematic diagram for frequency division by two.

the harmonic generator and the associated filter may be omitted.

To show how this circuit is related to Mathieu equations, consider first the ideal mixer (which does not load the filter circuit and which has zero output impedance) as shown in the frequency divider circuit (k=1) of Fig. 3. If the mixer is a multiplier so that  $v_m = -v_i v_o / K_m$  then the differential equation for the circuit can be shown to be

$$\frac{d^2v_o}{dt^2} + \frac{1}{LC} \left( 1 + \frac{v_i}{K_m} \right) v_o = 0$$

If the input signal is sinusoidal,  $v_i = V \cos \omega_i t$ , then this equation is of the form

$$\frac{d^2 \vec{v_o}}{dt^2} + \frac{1}{LC} \left( 1 + \frac{V}{K_m} \cos \omega_i t \right) v_o = 0$$

which is a special case of the Mathieu equation  $y^{11} + (\alpha + \beta \cos x) y = 0$ 

If the losses in the mixer and in the filter circuit are included in the calculations as indicated in Fig. 4, then the differential equation for the output voltage has the form

$$\frac{d^2v_o}{dt^2} + 2\delta \frac{dv_o}{dt} + \nu^2v_o = 0$$

# NEW Automatic Electronic Cable-making Machine Announced

(Los Angeles, California) After years of development, The Zippertubing Company announces production of a machine which automatically makes cables at speeds up to 900 feet per hour. This machine, occupying only 24 square feet of floor space, produces cables with up to 108 conductors and is so simple to operate that inexperienced personnel can make cables to any specification.

This new equipment utilizes the revolutionary Zippertubing cable jacketing, which is fed into the machine along with the required number of conductors. The Zippertubing then is automatically wrapped around the conductors, zipped closed and, if required, permanently fused with a chemical sealer. The completed cable automatically is wound on the take-up reel for storage or shipping. The machine will produce cable from %" to 2½" O.D. with larger sizes on special order.

Complete unit with wire reels in place.

#### MULTI-JACKETED CABLES IN ONE STEP

By using Zippertubing laminated materials, cables which require jackets of several different materials can be made in one step without costly re-handling. Available jackets include copper, aluminum or Co-netic steel in combination with such materials as vinyl, Mylar,\* or fiber glass. Other laminates for high temperature exposure, abrasion protection, etc., also may be used in the machine.

#### SUBSTANTIAL SAVINGS

Up to 90% of the labor costs formerly involved in fabricating cables are eliminated through the use of the Zippertubing Cable Machine. Only limited floor space is necessary for long-run continuous lengths, and material waste, skilled labor investment and expensive extruding equipment no longer are required. Expensive "minimum" orders for custom extruded cabling as well as delay in deliveries also are eliminated. Because of the flexibility of Zippertubing, small

\*Trademark of duPont.

ductors, virtually eliminating the great costs formerly incurred in correcting mistakes in prototype development.

cable runs for R & D work are economically feasible. Zipper-

tubing cables can be re-opened for additional work on con-

Close-up of head showing Zippertubing jacketing and conductors being formed into cable and automatically sealed.

#### MEET MIL SPEC

Cables produced on this new equipment meet all necessary MIL specs, depending on the jacketing material and the purpose for which it is to be used.

#### CABLE MACHINE FREE

One of the purposes of this new machine is to help manufacturers reduce their capital investment and inventory in electronic cables. A special plan has been developed whereby manufacturers who use 10,000 feet or more of Zippertubing jacketing per month will be provided with one of these machines at no cost. For those with more modest requirements, the machine may be leased very inexpensively with option to buy, or it may be purchased outright. A 100% lifetime guarantee is available under all plans. When ordering, allow three weeks for delivery.

#### AVAILABLE IN THREE PARTS

The Zippertubing cable machine may be ordered in three units: basic unit, which includes the head and sealing device; wire payoff unit, which contains the "tree" and spindles for holding the wire reels; power unit, which has the take-up reel spindle, frame and 115 V AC/DC motor that pulls the cable through the complete process.

For complete catalog information or field engineering service, write to the manufacturer: The Zippertubing Company, 752 So. San Pedro St., Los Angeles 14, California. TWX LA 840. Sales offices and warehouses are located in all principal cities.

# Frequency Cut-Of A

N AN inductive attenuator the  $H_{11}$  mode is excited and received in a cylindrical waveguide whose length is made variable by use of a "line-stretcher" and which is excited by means of coupling loops. The basic arrangement is shown in Fig. 1. In Figs. 2 and 3 the two types of attenuators used are presented.

It can be shown that in a Type 1 attenuator the voltage ratio is proportional to the wavelength. Moreover for small values of distance 1 the voltage division is proportional to sinh (4.81 1/d).

For Type 2 attenuation is independent of wavelength. Both attenuators have similar characteristics as a function of l.

Abstracted from an article by A. Sander, Nachrichtentechnische Zeitschrift, Vol. II, No. I, Jan. 1958, pp. 1-5.

# Modulated Light

HE MODULATION of light by means of standing waves in a fluid is possible because the refractive index of fluids is a function of the degree to which it is compressed. To accomplish modulation an ultrasonic quartz crystal is placed at one end of a column of fluid as shown in the illustration. A reflector is placed at the other end. If the crystal is excited, then standing waves, i.e. compressions and refractions, are set up in the fluid. In order to have the entire surface of the crystal oscillate with the same phase, an excitation frequency somewhat lower than the natural frequency of the crystal is used.

Because of the standing sound waves in the liquid, the refractive index, n, will vary in accordance with the law

$$\frac{C}{n \pm \Delta n} = \Delta v \pm v$$

C is the velocity of light in vacuum, and v is the velocity of light in the fluid under normal presncyResponse of

#### Relays

MIL-R-25018(USAF), RELAYS, MINIATURIZED, HERMETICALLY SEALED, AIRBORNE EQUIPMENT, GENERAL SPECIFICATION FOR, AMENDMENT 1, 12 February 1958

The requirements for Sealing Test 1 have been changed to read: the leakage rate shall not exceed an equivalent rate of 3cc of helium (at standard conditions) in ten years. An alternate method for making this test may use a radioactive tracer method with an inert, nontoxic, radioactive gas such as Krypton.

#### **Switches**

MIL-S-3950A, Toggle Switches, Amendment 1, 1 April 1958

Terminals not functionally required as indicated in the applicable standard need not be supplied. Group A inspection has been revised to indicate that quality acceptance levels shall be as specified in Table II. Major and minor defects shall be as defined in MIL-STD-105.

#### Crystal Holders

MIL-H-10056C, GENERAL SPECIFICATION FOR CRYSTAL HOLDERS, 20 MARCH 1958

The scope of the spec has been changed so that the spec now covers only metal and glass crystal holders. The plastic crystal holder HC-5/U has been deleted. A metal holder HC-21/U, which is electrically and physically equivalent to HC-5/U, has been added.

#### Solenoids

MIL-S-4040C, GENERAL SPECIFICATION FOR ELEC-TRICAL SOLENOIDS, 23 JANUARY 1958

The general requirements for aircraft solenoids are covered in this spec. The solenoids may be either continuous duty or intermittent duty types. Solenoids meeting the requirements of this spec are of compact design and of sufficiently rugged construction to withstand the mechanical shocks and stresses incident to their use in aircraft. The solenoid coils are terminated with an electrical connector conforming to MIL-C-5015 on terminals of the screw-stud type. This spec supersedes MIL-S-004040B(USAF) and MIL-S-

ECTRONIC DESIGN • September 17, 1958

MIL-C-3965B, CAPACITORS, FIXED, ELECTROLYTIC (TANTALUM) GENERAL SPECIFICATION FOR, 3 APRIL

The overvoltage requirement has been replaced by a surge voltage requirement. The life test has been increased from 1000 hours to 2000 hours. Various electrical requirements have been changed. This issue supersedes coordinated spec MIL-C-3965 and single-service spec MIL-C-003965(USAF).

MIL-C-26244(USAF), CAPACITORS, FIXED, PAPER (OR PAPER-PLASTIC) DIELECTRIC, D-C, HIGH RE-LIABILITY (HERMETICALLY SEALED IN METALLIC Cases), 31 January 1958

This spec is intended for capacitors used primarily for filter, by-pass, and blocking purposes, where the a-c component of the impressed voltage is small with respect to the d-c voltage rating. It is the intent of this spec that the manufacturer shall control the quality of his production to an AQL of 0.4% or below. Capacitors having this quality will have a minimum failure rate ranging from 0.01%/1,000 hours to 0.97%/1,000 hours depending upon the manner in which used. Capacitors meeting this spec may be used a full rated voltage at 125°C with an expected failure rate of less than 1% per 1,000 hours. A typical type designation of capacitors meeting this spec is CPV08A1E1041.

#### Microfilm Storage

ASA PH5.4-1957, AMERICAN STANDARD PRACTICE FOR STORAGE OF MICROFILM

Humidity, temperature, dust, or gas will not ruin microfilm records if the microfilm is stored as outlined in this standard. All the problems involved in storge, ways to protect and methods of inspection to insure safety of microfilm, are outlined in this new standard. The standard gives storage provisions for commercial permanence, that is, for microfilm to be used within approximately 25 years; for archival permanence, for microfilm that must be kept safely for maximum period obtainable; and for protection against fire. The standard covers general principles of humidity during storage, temperature, impurities in the air, fire protection, reels on which microfilm is wound, containers for storing microfilm, storage housing, storage rooms, conditions of air and inspection. A comprehensive bibliography is also included. Copies of this standard are available from the American Standard Association, 70 East 45 Street, New York 17, N.Y. at 50 cents a copy.

Research and Development ENGINEERS

opportunities with MOTOROLA in Chicago

Here is opportunity unlimited for men who like challenges and the rewards that go with accomplishment. Grow right along with dynamic 2-way radio communications, or work on important assignments from the armed forces.

You'll enjoy working at Motorola in well-instrumented laboratories, with men of the highest technical competence. Many liberal employee benefits, including an attractive profit sharing plan.

Living in one of Chicago's beautiful suburbs, you can choose from endless social, cultural and educational activities the year round.

# MILITARY POSITIONS OPEN

- Radar transmitters and receivers
- Radar circuit design
- Antenna design
- Electronic countermeasure systems
- Military communications equipment design
- · Pulse circuit design
- IF strip design
- Device using kylstron, traveling wave tube and backward wave oscillator
- Display and storage devices

# CIVILIAN POSITIONS OPEN

#### 2-WAY RADIO COMMUNICATIONS

VHF & UHF Receiver • Transmitter design & development • Power supply
 Systems Engineering • Selective Signaling • Transistor Applications • Crystal Engineering • Sales Engineers

#### PORTABLE COMMUNICATIONS

 Design of VHF & UHF FM Communications in portable or subminiature development.

#### MICROWAVE FIELD ENGINEERS

Positions also available in:

## Phoenix-Ariz.

Riverside, Calif

write

Mr. L. B. Wrenn Dept. J MOTOROLA, INC. 4501 Augusta Blvd., Chicago 51, III.

#### A VIKING Padie

When the terrible green monster suddenly appeared alongside the good ship Viking Queen, all hands save one promptly disappeared over the side into the chill waters of the North Atlantic. Only Lief Smorgasbord, radar operator, remained aboard to face the beast.

If we may take a trembling Lief from history, we will follow the

conversation that ensued:

Lief (trembling): Why . . . why didn't you show up on my scope?

Monster (in a high, feminine voice): I'm enchanted, that's why!

Oh, Mr. Viking, I'm just a poor princess who has been bewitched and transformed into a teen-age she-sea serpent! If you could answer the

Lief (still trembling): The Mysterious Riddle?

Monster (hopefully): It goes like this.

Heart of that which has no ears, but hears; No eyes, but sees; no nose, but knows . . . Tube B or not Tube B, that is the question!

Lief managed to answer the riddle, breaking the spell and instantly transforming the monster into a lovely princess. And so they were married and lived happily ever after.\*

\* The single word was "Bomac," of course. Lief knew "Tube B or not Tube B" must refer to Bomac tubes, heart of any radar system ("that which has no ears, but hears, etc.") Smart one, that Smorgasbord.

#### No. 5 of a series ... BOMAC LOOKS AT RADAR THROUGH THE AGES

\*Bomac makes the finest microwave tubes and components either side of the Atlantic

Leaders in the design, development and manufacture of TR, ATR, Pre-TR tubes; shutters; reference cavities; hydrogen thyratrons; silicon diodes; magnetrons; klystrons; duplexers; pressurizing windows; noise source tubes; high frequency triode oscillators; surge protectors.

# TO MAKE YOUR EQUIPMENT SMALLER YET MORE RELIABLE

#### REVOLUTIONARY TRANSISTOR\* TRANSFORMERS, HERMETIC TO MIL-T-27A

Conventional miniaturized transistor transformers have inherently poor electrical characteristics, perform with insufficient reliability and are woefully inadequate for many applications. The radical design of the new UTC DO-T and DI-T transistor transformers provides unprecedented power handling capacity and reliability, coupled with extremely small size.

#### TYPICAL DO-T PERFORMANCE CURVES

Power curves based on setting output power at 1 KC, then maintaining same input level over frequency range.

DO-T

5/16 Dia. x 13/32, 1/10 Oz.

High Power Rating ... up to 100 times greater.

Excellent Response . . . twice as good.

Low Distortion . . . reduced 80%.

High Efficiency ... up to 30% better.

Moisture Proof . hermetic to MIL-T-27A.

Rugged . . . completely cased.

Anchored Leads . . . will stand 10 lb. pull, plastic leads for printed circuits.

DI-T

1/16 Dia. x 1/4, 1/20 Oz.

To fully appreciate D0-T transistor transformers, the curves indicate their performance compared to that of similar size units now on the market. D1-T transformers are still smaller in size. Power rating and other characteristics are identical to D0-T, but low frequency response (3 db down point) is 30% higher in frequency. Units can be used for different impedances than those shown, keeping in mind that impedance ratio is constant. Lower source impedance will improve response and level ratings... higher source will reduce them. Units may be used reversed, input to secondary.

DO-T No.	MIL Type	Application	Pri. Imp.		D.C. Ma.:	Sec		Pri. Res.	Level Mw.	DI-T No.
DO-T1	TF4RX13YY	Interstage	20,000 30,000		.5 .5	800 1200		850	50

#### **REVOLUTIONARY TRANSISTOR\* TRANSFORMERS, HERMETIC TO MIL-T-27A**

Conventional miniaturized transistor transformers have inherently poor electrical characteristics, perform with insufficient reliability and are woefully inadequate for many applications. The radical design of the new UTC DO-T and DI-T transistor transformers provides unprecedented power handling capacity and reliability, coupled with extremely small size.

#### TYPICAL DO-T PERFORMANCE CURVES

Power curves based on setting output power at 1 KC, then maintaining same input level over frequency range.

\*DO-T units have been designed for transistor application only ... not for vacuum tube service. Patents Pending

> SPECIAL UNITS AVAILABLE TO YOUR SPECIFICATIONS.

# DO-T

5/16 Dia. x 13/32, 1/10 Oz.

High Power Rating . . . up to 100 times greater.

Excellent Response . . . twice as good. Low Distortion . . . reduced 80%.

High Efficiency ... up to 30% better.

Moisture Proof . hermetic to MIL-T-27A.

Rugged . . . completely cased.

Anchored Leads . . . will stand 10 lb. pull, plastic leads for printed circuits.

5/16 Dia. x 1/4, 1/20 Oz.

To fully appreciate DO-T transistor transformers, the curves indicate their performance compared to that of similar size units now on the market. DI-T transformers are still smaller in size. Power rating and other characteristics are identical to DO-T, but low frequency response (3 db down point) is 30% higher in frequency, Units can be used for different impedances than those shown, keeping in mind that impedance ratio is constant. Lower source impedance will improve response and level ratings . . . higher source will reduce them. Units may be used reversed, input to secondary.

DO-T No.	MIL Type	Application	Pri. Imp.		D.C. Ma.‡ in Pri.	Sec. Imp.	Pri. Res.	Level Mw.	DI-T No.

# RCA-6AW8-A

# -Preferred Tube Type-Offers You Extended Life, Improved Performance

The popular RCA-6AW8-A features highly improved performance and longer life in video-amplifier service -improvements resulting directly from RCA's Preferred Tube Types Program!

#### THESE IMPROVEMENTS WERE MADE TO THE RCA-GAW8-A

Precise control of heater coatings eliminates "thin spots"-assures durable heaters which minimize heater-cathode leakage and heater-cathode shorts. Special-alloy cathodes offer better cathode activation which reduces slump and assures stable operation. A new cathode design reduces the number of weldsminimizing handling and contamination.

Heat dissipation is improved by the use of heavier side rods on pentode grid #1. Pure nickel pins reduce pin-contact noise and facilitate insertion and removal of the tube. From tip to stem, the glass is controlled for stress and strain to assure durability under wide variations in temperatures. Final test procedures include cycled operational life tests to

simulate "on-off" usage in the home.
Result: the highly reliable RCA-6AW8-A for superior video amplifier performance. By designing your circuits "around" proved-in-service Preferred Tube Types, such as the 6AW8-A, you take advantage of the benefits of lower tube costs, more uniform tube quality and better tube availability.

There's a Preferred Tube Type to meet virtually all of your TV, AM and FM receiver requirements. Ask your RCA Representative for the up-to-date list of 62 Preferred Types. Or, write Commercial Engineering, Section I-18-DE-2.
