DEWALD RADIO

MODEL B-401

DEWALD RADIO

MODEL B-504

The DeWald model B-504 is a combination portable battery receiver. This receiver uses the latest type tubes for best performance. The circuit used is designed for excellent reception and long battery life.

The receiver uses an "A" supply of $4\frac{1}{2}$ volts and a "B" supply of $67\frac{1}{2}$ volts.

For good reception the life of the batteries is from 70 to 80 hours when the receiver is used about two hours per day.

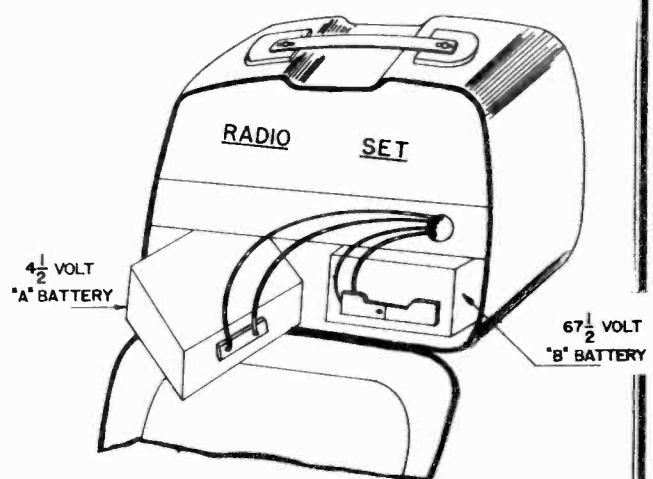

The following or similar batteries may be used with this receiver:

"A" BATTERY $4\frac{1}{2}$ V "B" BATTERY $67\frac{1}{2}$ V

Eveready #746	*467
General #3H3	*W45A
Ray O Vac #P83A	*P4367
Burgess #G3	*XX45

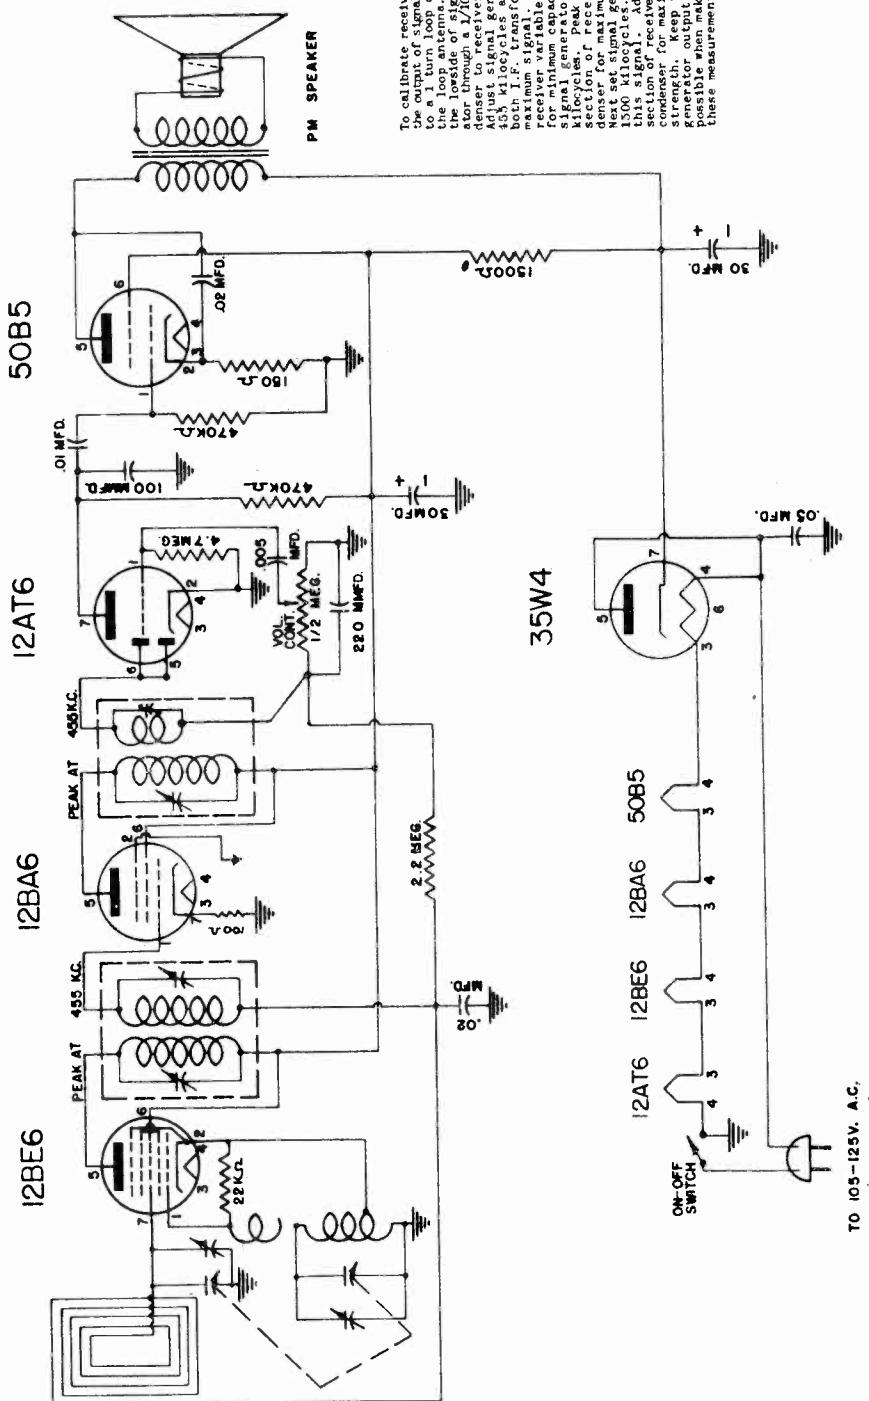

To install the batteries in the receiver, proceed as follows:

1. Open back by inserting fingers in slots provided on top of cabinet and pull back open.
2. Connect battery clips to batteries.
3. Put batteries in set as shown in sketch.
BE CAREFUL NOT TO BREAK WIRES CONNECTED TO LOOPTENNA.

With the receiver on and the volume control at maximum, connect the signal generator to the coupling loop and bring the loop close to the receiver chassis. Adjust the signal generator output to minimum necessary to give a suitable indication on the output meter, which should be connected from B minus to the plate of one output tube. CAUTION: Make sure the output meter is isolated from DC by a series blocking condenser.

With the gang condenser fully meshed, adjust the pointer so that the left hand edge of the pointer saddle is one inch from the end of the dial frame. (See Dial Installation drawing) Using the dial scale contained in this Service Bulletin, align the pointer to the indicated reference mark with the pointer set as above. Then proceed with the alignment in accordance with the chart below:

SET SIGNAL GENERATOR AT	SET GANG	LOOP DISTANCE	ADJUST TRIMMER	TUNE FOR	OPERATION
455 KC	Meshed	Close	9a 9b 10a 10b	Max.	Align - I.F.
1720 KC	Fully Open	Close	20a	Max.	Align Oscillator
1400 KC	1400 KC	Close	20b	Max.	Align - R.F.

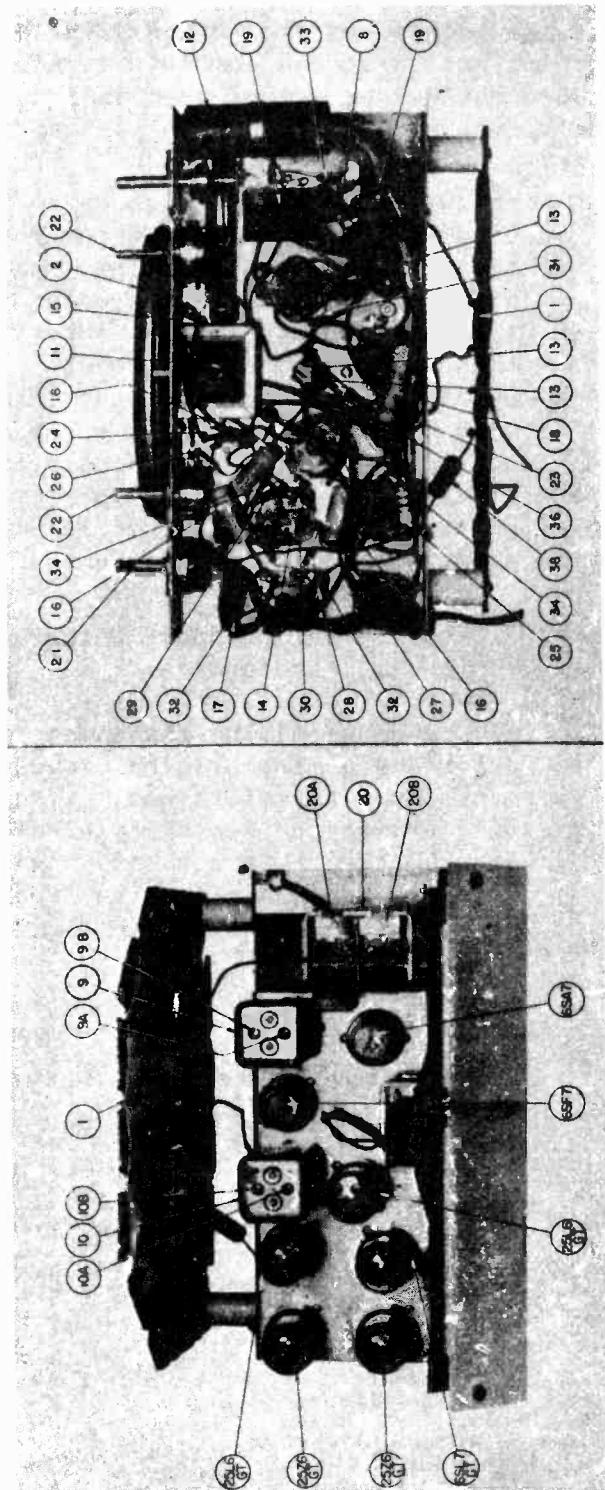

All DC voltage measurements in this Service Bulletin have been made with a 20,000 ohms per volt voltmeter, using B minus as a common reference point. All AC voltage measurements are with 1000 ohms per volt voltmeter. Line voltage was maintained at 117 volts for all voltage measurements. The condenser gang should be fully meshed and the volume control at its minimum point. Voltages may vary $\pm 10\%$ from the indicated nominal value.

Measurements of oscillator grid bias voltage should be made with a 50,000 ohm resistor in series with the negative probe of the meter, and the positive prod connected to B minus. Rotate the tuning condenser throughout its complete range with the meter connected. Absence of bias voltage at any point is an indication that the oscillator is not functioning.

Alignment Procedure

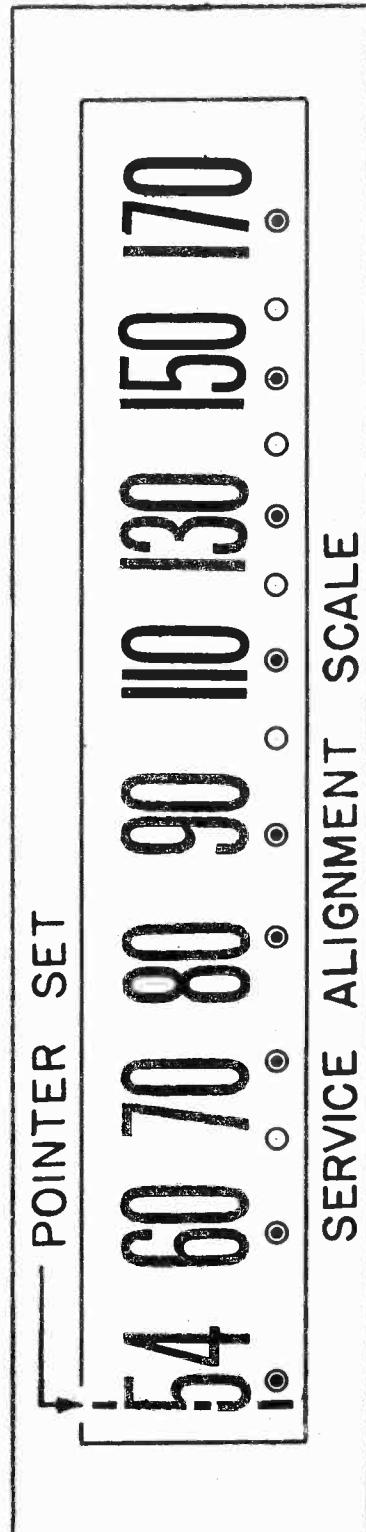

In order to make a proper alignment, the following equipment is required:

1. A signal generator capable of providing a modulated radio frequency output over the frequencies required.
2. A suitable output meter or sensitive AC voltmeter with a .1 mfd series blocking condenser.
3. A coupling loop, made of three turns of stiff hookup wire, 4 inches in diameter, mounted on a suitable block of wood or stand.
4. A non-metallic screwdriver.

Chassis Top View

**Replacement of I.F. Transformers**

When replacing intermediate frequency transformers, either input or output, use caution to observe original lead dress.

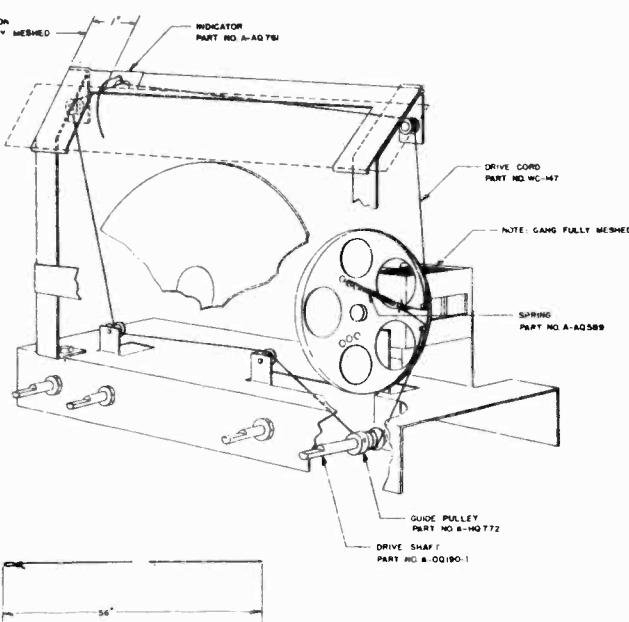

MODEL 132

ELECTRONIC CORP. OF AMERICA
 Replacement of Dial Drive Cord

Completely remove remainder of defective dial cord. Inspect all pulleys and make sure they revolve freely. Determine that no grease or oil is present on any pulley surface. Attach the cord spring, part #A-AQ589, to one end of the drive cord. Fully mesh the gang condenser and hook the spring to the hole closest to the cord cutout on the dial drum. Proceed to string dial cord in accordance with the detail drawing. Take two full turns around the drive drum, part #A-HQ772. Pull the cord snug at this point. Wrap one complete turn around gang drum and pull cord snug. Securely tie free end of cord to the cord spring. Next, adjust spring tension by moving the hook end of the spring into the next spring hole.

Clip the pointer on to the dial cord with sufficient tension so as to prevent slippage and adjust pointer position, so that with fully meshed gang,

the left edge of the pointer saddle is one inch from the edge of the dial support frame. Insert chassis in cabinet and check pointer and scale agreement. Then make final adjustment of pointer position. Remove the chassis and firmly crimp the pointer prongs on the dial cord, and secure with a small drop of speaker cement.

Replacement of Audio Output Transformers

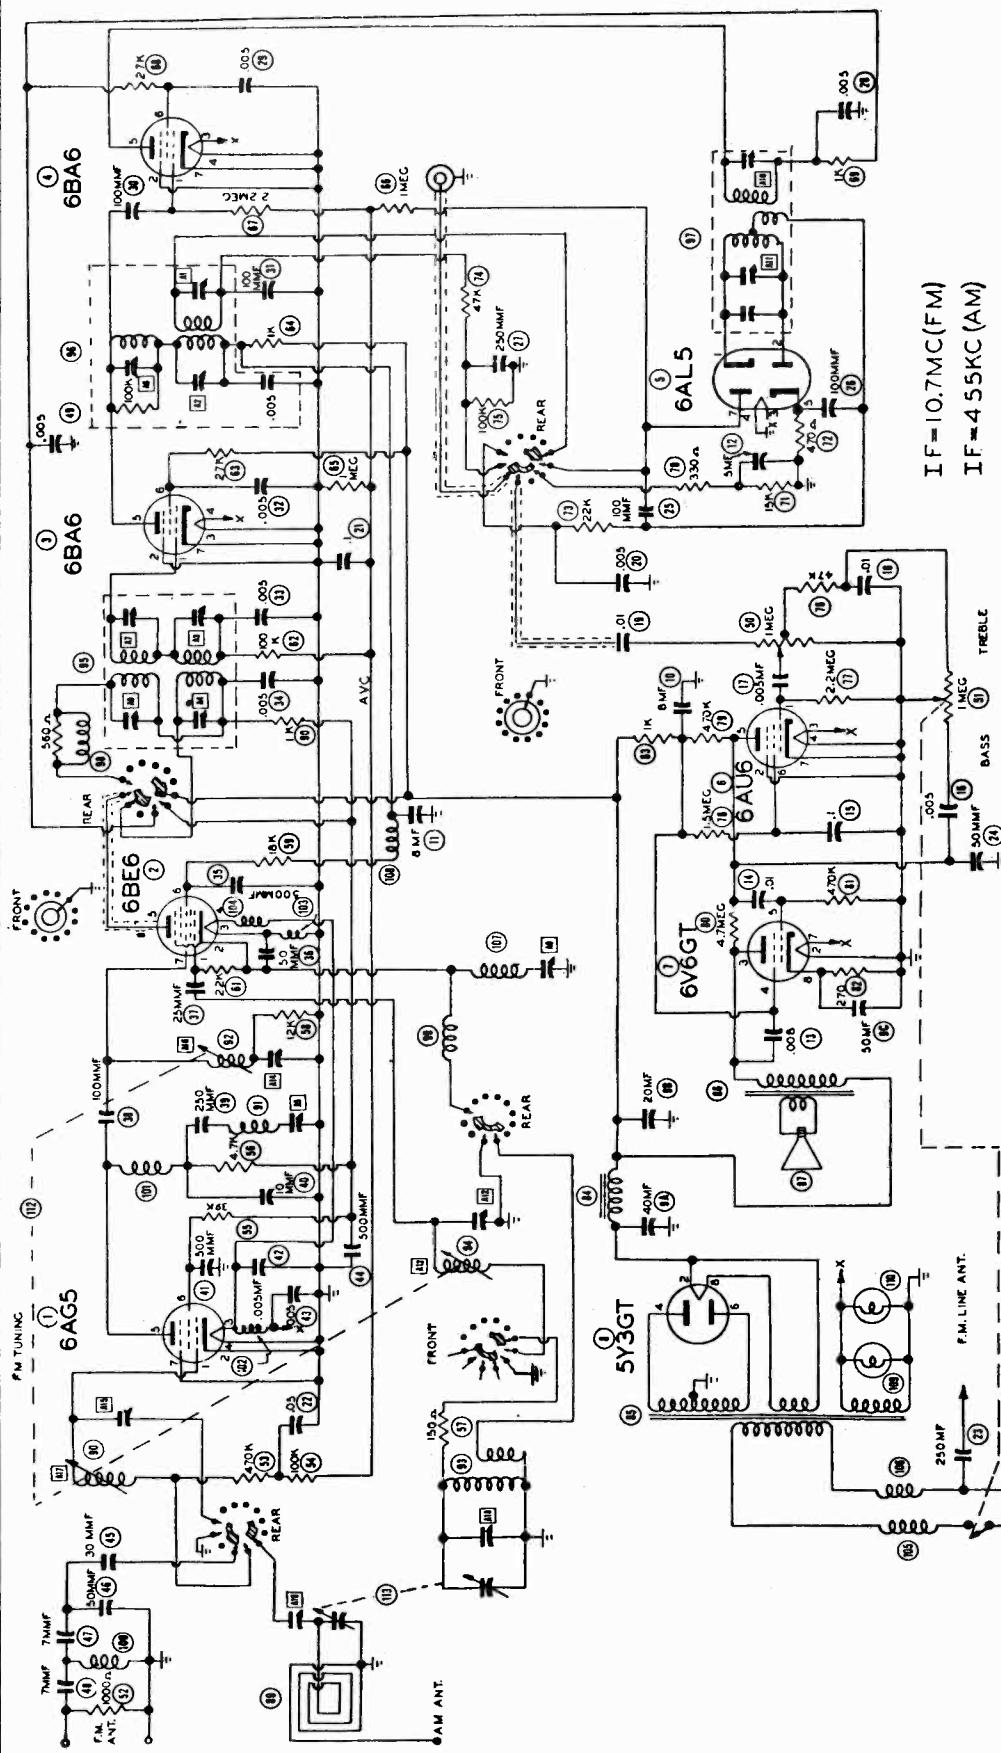

When replacing the audio output transformer, original lead dress must be maintained. If either primary or secondary windings are reversed, the set will have a severe audio oscillation, due to the inverse feedback network.

EMERSON RADIO AND PHONO. CORP. MODEL 528,
CHASSIS 120038

DESCRIPTION

TYPE: Amplitude modulation (AM) and frequency modulation (FM) superheterodyne.

FREQUENCY RANGE:

Broadcast band (AM) — 530-1620 kilocycles
Frequency modulation band (FM) — 87.75-108.5 megacycles

TYPE OF TUBES:

- 1—6AG5, r-f amplifier
- 2—6BA6, first i-f amplifier and FM second i-f amplifier
- 2—6BE6, converter
- 1—6AL5, FM-AM detector, a.v.c.
- 1—6AU6, a-f amplifier
- 1—6V6GT, power output
- 1—5Y3GT, rectifier

POWER SUPPLY: 60-cycle a.c.
VOLTAGE RATING: 105-125 volts.
POWER CONSUMPTION: 80 watts.
CURRENT DRAIN: 0.75 amp. at 117 volts a.c.

CHASSIS 120038

ALIGNMENT

To set pointer turn variable condenser fully closed and set pointer to last reference mark at low-frequency end of dial. To inject signal in Steps 4, 5 and 6, remove tube and connect wire to pin 1. Replace tube, making certain that wire does not short to shield base. For Step 8, connect two 100,000 ohm resistors in series from pin 7 of 6AL5 to chassis. After Step 8, turn variable condenser fully counterclockwise and check adjustment of FM tuning unit per dial cord drawing. Volume control should be at maximum position; output of signal generator should be no higher than necessary to obtain an output reading. Use an alignment screwdriver for adjusting.

	DUMMY ANTENNA	SIGNAL GENERATOR COUPLING	SIGNAL GENERATOR FREQUENCY	BAND SWITCH POSITION	RADIO DIAL SETTING	OUTPUT METER	ADJUST	REMARKS
1	0.1 mfd.	High side to stator of front section of the variable condenser. Low side to chassis.	455 kc	BC (center position)	High frequency end of dial.	Across voice coil.	A1, A2, A3, A4	Adjust for maximum output.
2	0.1 mfd.	High side to stator of front section of the variable condenser. Low side to chassis.	455 kc	BC (center position)	Low frequency end of dial.	Across voice coil.	A5	Adjust for minimum output.
3	0.05 mfd.	High side to pin 1 (grid) of 6BA6, 1st 1-f tube (3). Low side to chassis.	10.7 mc (unmodulated)	FM (fully clockwise)	High frequency end of dial.	VTVM connected to pin 7 of 6AL5 and chassis.	A6	Adjust for maximum deflection.
4	0.05 mfd.	High side to pin 1 (grid) of 6BE6. Low side to chassis.	10.6 mc (unmodulated)	FM (fully clockwise)	High frequency end of dial.	VTVM connected to pin 7 of 6AL5 and chassis.	A7	Adjust for maximum deflection.
5	0.05 mfd.	High side to pin 1 (grid) of 6BE6. Low side to chassis.	10.8 mc (unmodulated)	FM (fully clockwise)	High frequency end of dial.	VTVM connected to pin 7 of 6AL5 and chassis.	A8	Adjust for maximum deflection.
6	0.05 mfd.	High side to pin 1 (grid) of 6BE6. Low side to chassis.	10.7 mc (unmodulated)	FM (fully clockwise)	High frequency end of dial.	VTVM connected to pin 7 of 6AL5 and chassis.	A9	Adjust for maximum deflection.
7	0.05 mfd.	High side to pin 1 (grid) of 6BA6, 2nd 1-f tube (4). Low side to chassis.	10.7 mc (unmodulated)	FM (fully clockwise)	High frequency end of dial.	VTVM connected to pin 7 of 6AL5 and chassis.	A10	Adjust for maximum deflection.
8	0.05 mfd.	High side to pin 1 (grid) of 6BA6, 2nd 1-f tube (4). Low side to chassis.	10.7 mc (unmodulated)	FM (fully clockwise)	High frequency end of dial.	VTVM connected from junction of two 100,000 ohm resistors and junction of condensers 25 and 26. (See preliminary alignment notes.)	A11	Adjust for zero deflection.
9	150 ohms in series with each lead.	High side to "A," low side to "G" on FM antenna terminals. Disconnect internal antenna.	108 mc (unmodulated)	FM (fully clockwise)	108 mc	VTVM connected to pin 7 of 6AL5 and chassis.	A 12	Adjust for maximum deflection.
10	150 ohms in series with each lead.	High side to "A," low side to "G" on FM antenna terminals. Disconnect internal antenna.	88 mc (unmodulated)	FM (fully clockwise)	88 mc	VTVM connected to pin 7 of 6AL5 and chassis.	A 13	Adjust iron core (hold brass in position) for maximum deflection.
11	150 ohms in series with each lead.	High side to "A," low side to "G" on FM antenna terminals. Disconnect internal antenna.	98 mc	FM (fully clockwise)	98 mc	VTVM connected to pin 7 of 6AL5 and chassis.	A 13	Adjust brass and iron cores (one screw) for maximum deflection. Repeat steps 9, 10 and 11 until no further improvement can be made.
12	150 ohms in series with each lead.	High side to "A," low side to "G" on FM antenna terminals. Disconnect internal antenna.	106 mc	FM (fully clockwise)	Tune for maximum deflection.	VTVM connected to pin 7 of 6AL5 and chassis.	A 14, A 15	Adjust for maximum deflection.
13	150 ohms in series with each lead.	High side to "A," low side to "G" on FM antenna terminals. Disconnect internal antenna.	90 mc	FM (fully clockwise)	Tune for maximum deflection.	VTVM connected to pin 7 of 6AL5 and chassis.	A 16, A 17	Adjust iron cores (hold brass in place) for maximum deflection.
14	150 ohms in series with each lead.	High side to "A," low side to "G" on FM antenna terminals. Disconnect internal antenna.	100 mc	FM (fully clockwise)	Tune for maximum deflection.	VTVM connected to pin 7 of 6AL5 and chassis.	A16, A17	Adjust both iron and brass cores for maximum deflection. Repeat steps 12, 13, and 14 until no further improvement can be made.
15	200 mmfd.	High side to "A," low side to "G" terminals of AM antenna terminals.	1600 kc	BC	1600 kc	Across voice coil.	A18	Adjust for maximum output.
16	20 mmfd.	High side to "A," low side to "G" terminals of AM antenna terminals.	1400 kc	BC	Tune for maximum output.	Across voice coil.	A19	Adjust for maximum output.

DIAL CORD DRIVE
DIAL CORD

INSTRUCTIONS FOR VOLTAGE AND RESISTANCE READINGS

- All readings taken in broadcast position except those for item 4A, 6BA6 tube, which should be taken in FM position.
- Voltage readings are in volts and resistance readings in ohms unless otherwise specified.
- D-C voltage measurements are at 20,000 ohms per volt; a-c voltages measured at 1,000 ohms.
- Socket connections are shown as bottom views.
- Measured values are from socket pin to common negative.
- Line voltage maintained at 117 volts for voltage readings.
- Nominal tolerance on component values makes possible a variation of $\pm 15\%$ in voltage and resistance readings.
- Volume control at maximum, no signal applied for voltage measurements.
- Resistance readings in the B+ circuits may vary widely according to the condition of the filter capacitors.

- If replacements are made or the wiring disturbed in the r-f section of the circuit, the receiver should be carefully realigned.

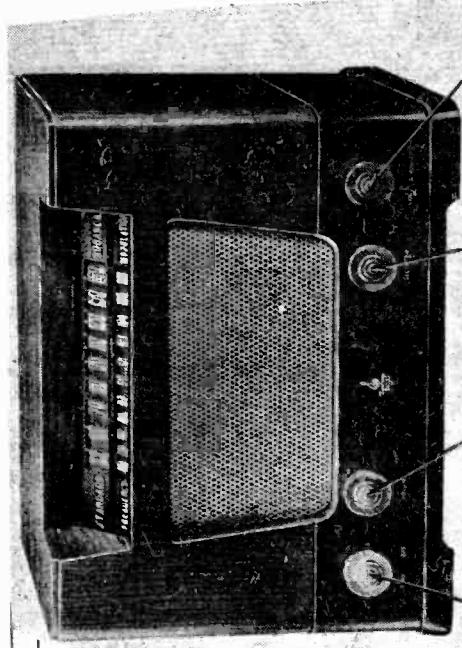

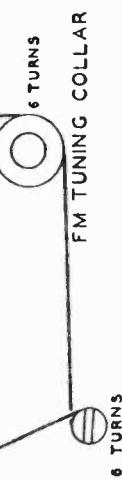

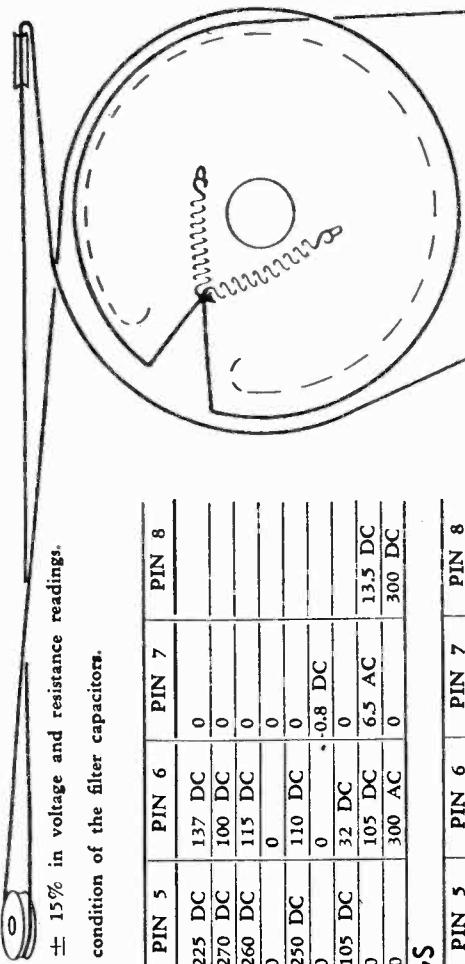

- The color coding of the i-f transformer leads is as follows:
Low—Green
Plate—blue
Grid—red

- A self-contained loop antenna is provided for broadcast band reception. For permanent home installation, however, if it is desired to improve reception of weak stations, an additional outdoor antenna may be used. Connect the outdoor antenna to the single screw terminal on the loop terminal marked BCST. ANT. The loop antenna operates at maximum efficiency when its position is at right angles to the broadcasting source. Once the station is tuned in, rotate the cabinet back and forth through a quarter of a circle, leaving it in the position where the station is received with maximum volume.

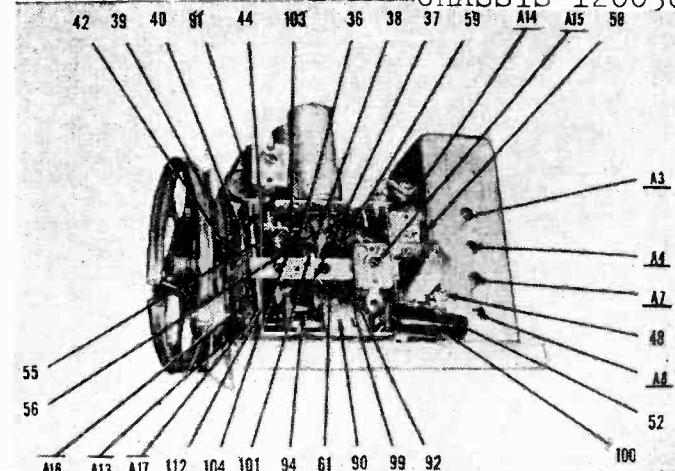

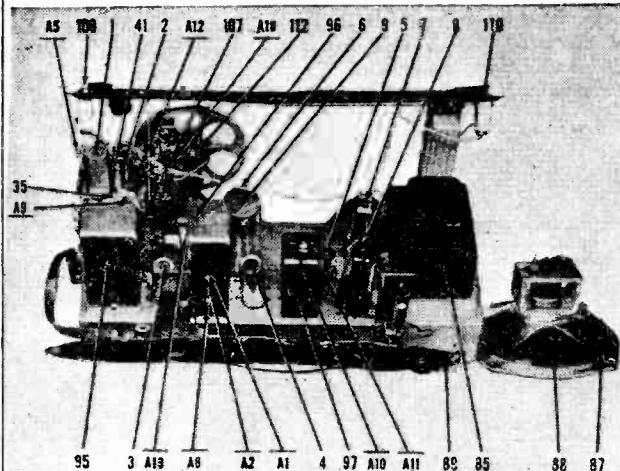

- An internal power line antenna is provided for FM operation in relatively strong signal areas. An external dipole antenna is recommended for maximum FM operation. To connect the dipole, remove the wire from the FM ANT. screw terminal "A" and connect the dipole leads to "A" and "G".
- A ground connection is not required for AM or FM operation.

ALIGNMENT

To set pointer on Models 540 and 564, turn tuning slugs completely in and set pointer to top reference dot on right side of dial backplate. On Model 572 set pointer in extreme clockwise position. Use isolation transformer if available. If not, connect a condenser in series with low side of signal generator and chassis. Volume control should be at maximum position; output of signal generator should be no higher than necessary to obtain an output reading. Use an insulated alignment screwdriver for adjusting.

	DUMMY ANTENNA	SIGNAL GENERATOR COUPLING	SIGNAL GENERATOR FREQUENCY	RADIO DIAL SETTING	OUTPUT METER	ADJUST	REMARKS
1	0.1 mfd.	High side to pin 7 (grid) of 12BE6. Low side to B—.	455 kc	Tuning slugs completely out.	Across voice coil.	A1, A2, A3, A4	Adjust for maximum output. If isolation transformer is not used, reduce dummy antenna to 0.001 mfd. to reduce hum modulation.
2	200 mmfd.	High side to external antenna lead. Low side to chassis.	1600 kc for Models 540 and 564. 1620 kc for Model 572	Bottom reference dot at right side of dial backplate for Models 540 and 564. Tuning slugs completely out on Model 572.	Across voice coil.	A5, A6	Adjust for maximum output.
3	200 mmfd.	High side to external antenna lead. Low side to chassis.	1400 kc	Tune for maximum output.	Across voice coil.	Antenna coil (34)	Loosen screws on bracket of antenna coil (34). Adjust position of coil for maximum output. Tighten screws.

VOLTAGE AND RESISTANCE READING INSTRUCTIONS

- Voltage readings are in volts and resistance readings in ohms unless otherwise specified.
- D-C voltage measurements are at 20,000 ohms per volt; a-c voltages measured at 1,000 ohms per volt.
- Socket connections are shown as bottom views.
- Measured values are from socket pin to common negative.
- Line voltage maintained at 117 volts for voltage readings.
- Nominal tolerance on component values makes possible a variation of $\pm 10\%$ in voltage and resistance readings.
- Volume control at maximum, no signal applied for voltage measurements.

DESCRIPTION

TYPE: Single-band superheterodyne.

FREQUENCY RANGE: 540-1620 kc.

TYPE OF TUBES:

- 1—12BE6, pentagrid oscillator-modulator
- 1—12BA6, first i-f amplifier
- 1—12AT6, diode detector, a-f amplifier, a.v.c.
- 1—50B5, beam power output
- 1—35W4, half-wave rectifier

POWER SUPPLY: A.C. or D.C.

VOLTAGE RATING: 105-125 volts.

POWER CONSUMPTION: 30 watts.

CURRENT DRAIN: 0.24 amp. at 117 volts a.c.

GENERAL NOTES

- If replacements are made or the wiring disturbed in the r-f section of the circuit, the receiver should be carefully realigned.
- In operating the receiver on d.c., it may be necessary to reverse the line plug for correct polarity.
- The color coding of the i-f transformer leads is as follows:

Grid—green

Grid return—black

Plate—blue

B+—red

CHASSIS 120062A**

POWER SUPPLY PLUG
PLUG INTO RECEPTACLE IN
RECEIVER. INSERT PLUG
ALL THE WAY.
FOR BATTERY OPERATION
REMOVE PLUG.

BATTERIES USED IN THIS RECEIVER		
TYPE	MANUFACTURER'S NUMBER	
6 Volt "A"	Olin No. 4919	Eveready No. 724
67½ Volt "B"	Olin No. 1712	Eveready No. 457

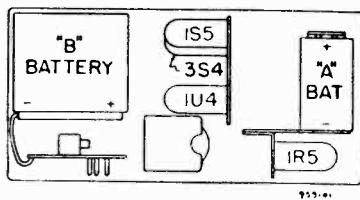

A.C.-D.C. OPERATION—Insert three-prong plug into socket on side of receiver. Plug Rectifier Unit into 105-125 volt wall outlet. Rectifier Unit will normally operate warm. Keep unit free from dust and in a well ventilated location. **OPERATE RECTIFIER UNIT IN HORIZONTAL POSITION ONLY.** If set is inoperative on D.C., reverse plug in wall outlet.

BATTERY OPERATION — Remove the three-prong plug from the receiver; the self-contained batteries will then supply power. Removal of Rectifier Unit from wall outlet is desirable.

BATTERY REPLACEMENT

1. Remove power supply plug from set.
2. Slide the button on the release catch near the handle in the direction of the arrow. This loosens the bottom shell and permits it to be swung open on the hinge, making the batteries accessible.
3. Insert the batteries as shown in the diagram.
4. To reassemble, hold the chassis face down with the batteries in place. Close the bottom shell over the chassis and press the handle end of the shell so that it snaps into place.

TUBE AND BATTERY LOCATIONS

INSTRUCTIONS FOR VOLTAGE AND RESISTANCE READINGS

- 1—DC Voltage measurements are at 20,000 ohms per volt; AC voltages measured at 1,000 ohms.
- 2—Socket connections are shown as bottom views.
- 3—Measured values are from socket pin to common negative.
- 4—Line voltage maintained at 117 volts for voltage readings.
- 5—Nominal tolerance on component values makes possible a variation of $\pm 15\%$ in voltage and resistance readings.
- 6—Volume control at maximum; no signal applied for voltage measurements

ALIGNMENT INSTRUCTIONS

Use battery power when available. If AC power is used, use an isolation transformer when available. If not, connect a .1 mfd. capacitor in series with low side of the signal generator and B—.

Volume control should be at maximum position; output of signal generator should be no higher than necessary to obtain an output reading. Use an insulated alignment screwdriver for adjusting.

	DUMMY ANTENNA	SIGNAL GENERATOR COUPLING	SIGNAL GENERATOR FREQUENCY	RADIO DIAL SETTING	OUTPUT METER	ADJUST	REMARKS
1	.1 mfd.	High side to Pin 6 (grid) of 1R5. Low side to B—.	455KC	Tuning cap. fully open.	Across voice coil.	A1, A2, A3, A4	Adjust for maximum output. If AC power is used without an isolation transformer reduce dummy ant. to 200 mmf. to reduce hum modulation.
2		Loop	1620KC	"	"	A5	Fashion loop of several turns of wire and radiate signal into loop of receiver. Adjust for maximum output.
3		"	600KC	Tune for maximum output.	"	A6	Rock tuning cap. and adjust for maximum output. Repeat Steps 2 and 3 until no further improvement can be made.

DESCRIPTION

TYPE: Three-way pocket portable superheterodyne.

FREQUENCY RANGE: 540-1600 kc.

TYPE OF TUBES:

- 1—1R5, oscillator-modulator
- 1—1U4, i-f amplifier
- 1—1S5, 2nd detector, a.v.c., a-f amplifier
- 1—3S4, pentode output

POWER SUPPLY: A.C.-D.C. (105-125 volts) or self-contained batteries

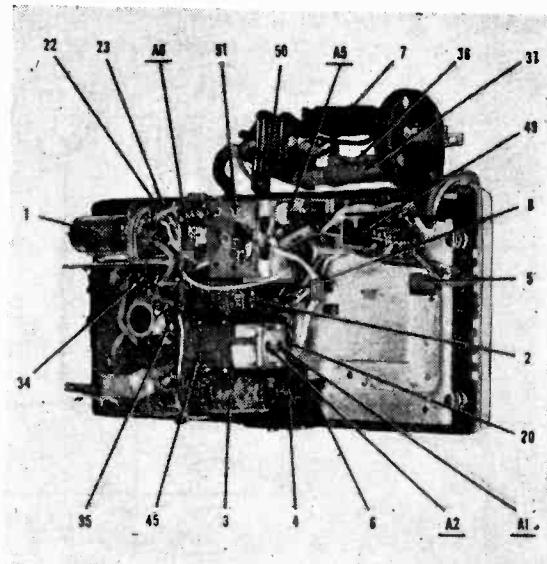

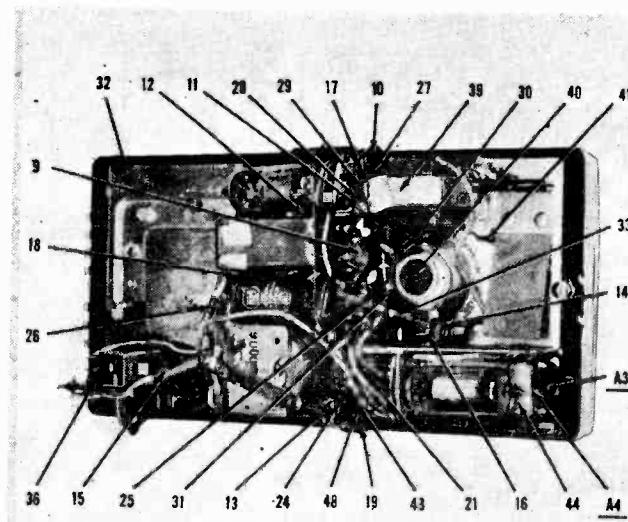

VOLTAGE RATING:

- "A" Battery—6 volts
- "B" Battery—67.5 volts

POWER CONSUMPTION: 11 watts

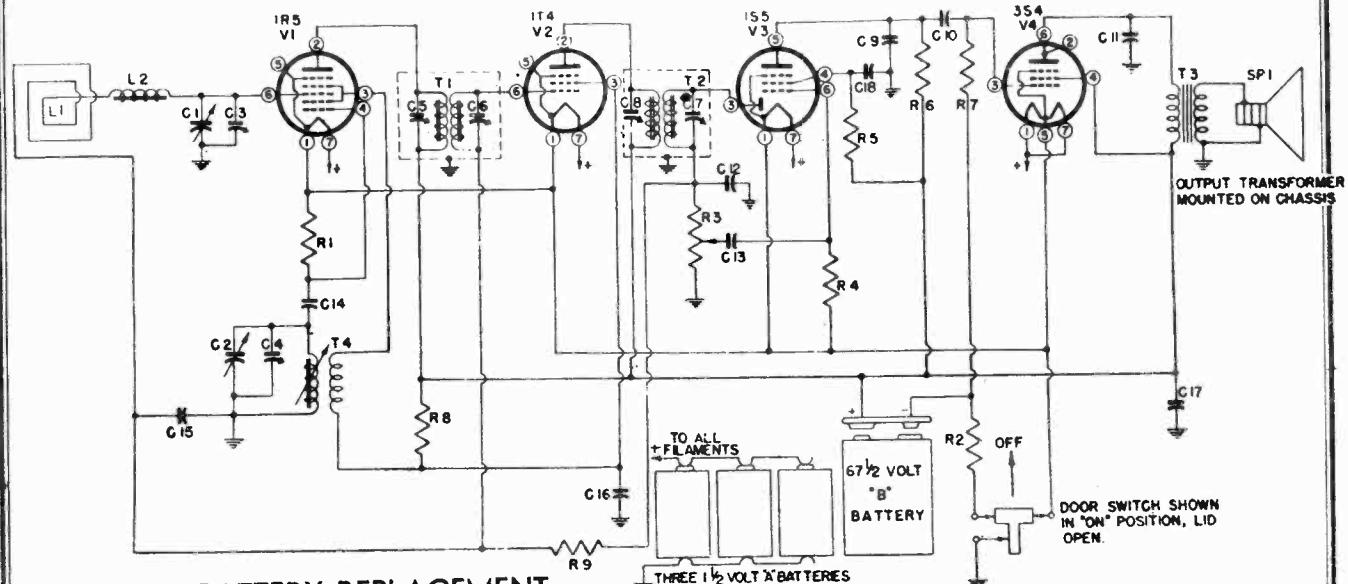

CURRENT DRAIN:

- "A" Battery—60 ma.
- "B" Battery—8 ma.

**BATTERY REPLACEMENT**

TO REPLACE BATTERIES: Close cover and turn set over. Unscrew large screw in center of base and remove bottom panel. This makes batteries accessible. Replace batteries as shown in illustration. Replace bottom panel and tighten screw.

BATTERIES MUST BE LOCATED
EXACTLY AS ILLUSTRATED

955134

**DESCRIPTION**

DESIGNATION: "Memento."

TYPE: Battery-operated superheterodyne.

FREQUENCY RANGE: 540-1600 kc.

TYPE OF TUBES:

- 1—1S5, 2nd detector, a.v.c., a-f amplifier
- 1—1R5, oscillator-modulator
- 1—1T4, i-f amplifier
- 1—3S4, pentode output

POWER SUPPLY: "A" and "B" batteries.

VOLTAGE RATING:

- "A" Battery—1.5 volts
- "B" Battery—67.5 volts

CURRENT DRAIN:

- "A" Battery—0.25 amp.
- "B" Battery—0.0075 amp.

ADJUSTMENTS

An oscillator with frequencies of 455, 600, 1420, and 1620 kc is required.

An output meter should be connected across the primary or secondary of the output transformer for observing maximum response.

Always use as weak a test signal as possible, turning down the output of the test oscillator as the alignment of the receiver progresses.

Turn the volume control on full.

Location of Coils and Trimmer Adjustments

The first i-f transformer is located next to the 1R5 tube. The trimmers are accessible through holes in the top of the can.

The second i-f transformer is located between the 1T4 and 1S5 tubes. Trimmers are accessible through holes in the top of the can.

The oscillator coil is located behind the on-off switch. The trimmer for the oscillator is located on the smaller variable condenser section. The 600 kc oscillator core adjustment is the brass screw protruding from the end of the oscillator coil.

The loop antenna acts as the antenna coil. The trimmer for the loop is located on the larger section of the variable condenser.

VOLTAGE ANALYSIS

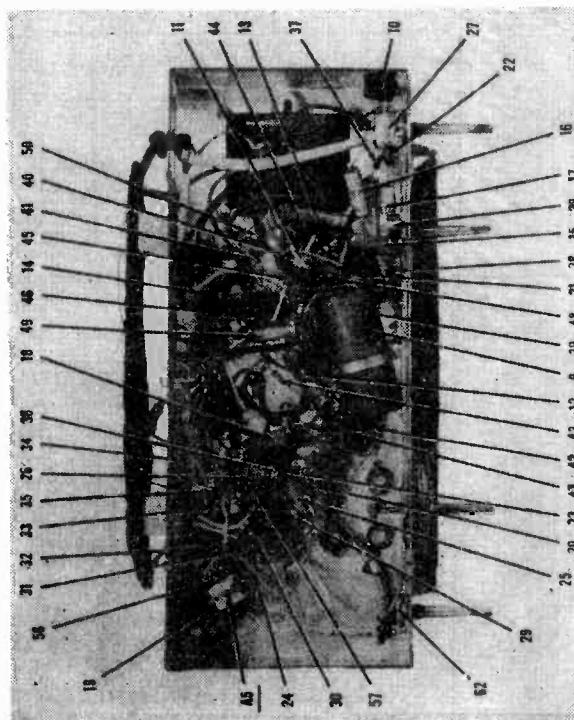

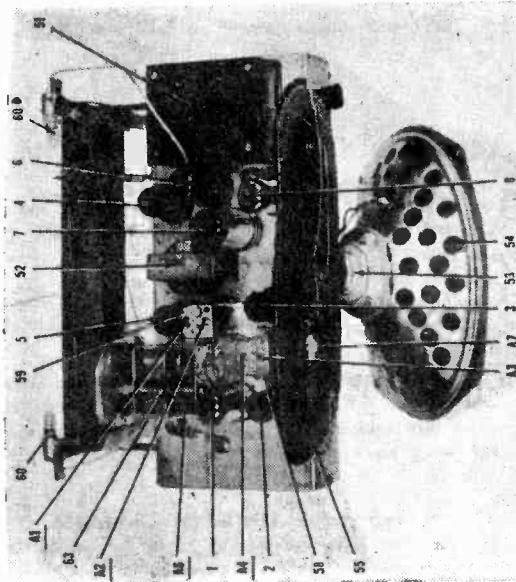

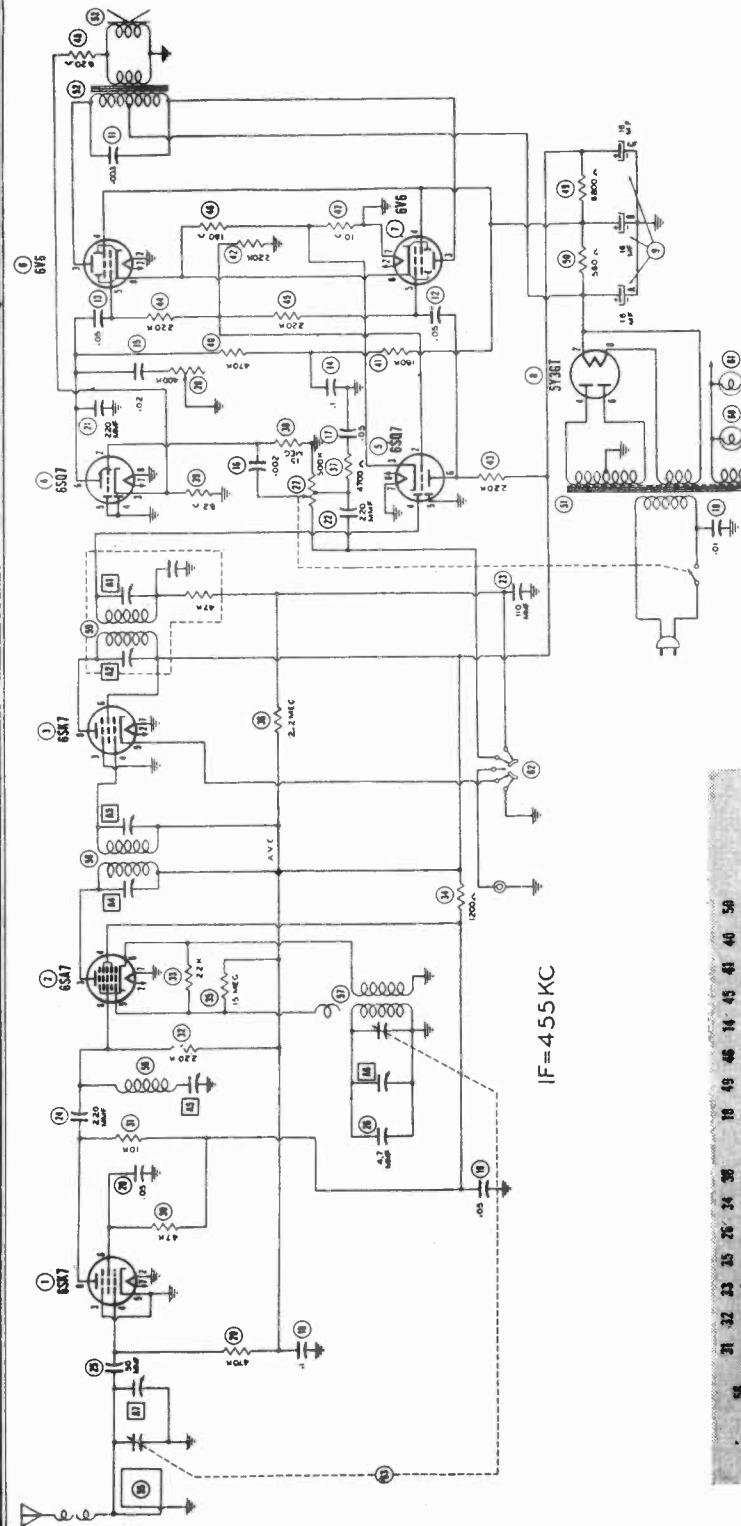

The following voltage readings are d-c measurements taken from B—(chassis) to the indicated tube-socket pin. A 1000 ohms-per-volt meter should be used for all readings except those indicated by an asterisk (*), which should be taken with a d-c vacuum-tube voltmeter. Take readings with the volume control set at minimum and the variable condenser closed. Use fresh batteries.

TUBE	PIN NUMBER						
	1	2	3	4	5	6	7

INSTRUCTIONS FOR VOLTAGE AND RESISTANCE READINGS

1—D.C. Voltage measurements are at 20,000 ohms per volt;
AC Voltages measured at 1,000 ohms per volt.

2—Socket connections are shown as bottom views.

3—Measured values are from socket pin to common negative.

4—Line voltage maintained at 117 volts for voltage readings.

5—Nominal tolerance on component values makes possible a variation of $\pm 10\%$ in voltage and resistance readings.

6—Volume control at maximum, no signal applied for voltage measurements.

ESPEY MFG. COMPANY, INC.

MODEL 501

4. Connect the "high" side of the Generator to the antenna terminal with a 200 mmf condenser inserted in series. Connect the "ground" side of the Generator to point "B".
5. Tune receiver to 150 on the dial. Adjust Signal Generator to 1500 kc. Adjust BC oscillator and BC antenna trimmers for maximum output. Use a weak signal for final adjustment.
- FM Equipment:**
 - a) 21.75 kc oscillator.
 - b) FM Signal Generator for 88 to 108 megacycle range.
 - c) Output meter.
1. Connect output meter across points "E" and "F".
2. With set switched on and volume control at maximum, feed modulated 21.75 mc signal into terminals "C" and "D".
3. Adjust tank coil for maximum response on output meter.
4. Disconnect 21.75 kc oscillator and connect FM signal generator to points "C" and "D".
5. Set receiver dial to 88 megacycles and adjust Signal Generator for same frequency. Adjust spacing of FM oscillator coil for maximum signal response.
6. Tune receiver to 108 megacycles and adjust Signal Generator to same frequency. Adjust FM oscillator trimmer for maximum signal response.
7. Repeat operations 5 and 6.
8. Tune receiver to 90 megacycles and adjust Signal Generator for same frequency. Adjust spacing of the FM antenna coil for maximum signal response with minimum background noise. Slowly rock tuning control while performing this adjustment.
9. Repeat operations 8 and 9.

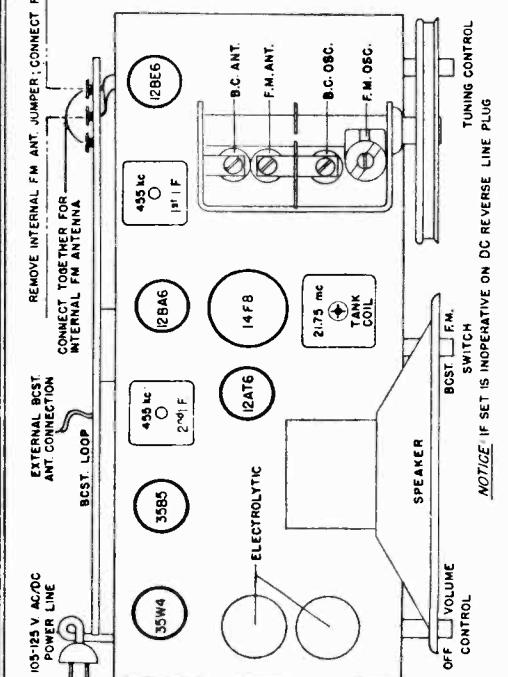

Equipment Required:

- a) 21.75 kc oscillator.
 - b) FM Signal Generator for 88 to 108 megacycle range.
 - c) Output meter.
1. Connect output meter across points "E" and "F".
2. With set switched on and volume control at maximum, feed modulated 21.75 mc signal into terminals "C" and "D".

MODEL 501

ESPEY MFG. COMPANY, INC.

John F. Rider

**POWER SOURCE:**

This receiver may be operated from either an AC or DC line, between 105 and 125 volts. On AC lines the frequency must be 50 to 60 cycles.

TUBE COMPLEMENT:

- 1 12BE6 — AM converter.
- 1 12BA6 — AM intermediate frequency amplifier.
- 1 12AT6 — AM demodulator and AVC; AM-FM 1st audio amplifier.
- 1 14F8 — FM oscillator-mixer-Super Regenerative I.F. amp.
- 1 35B5 — Audio output amplifier.
- 1 35W4 — Power rectifier.

INSTALLATION:**1. Antenna Connection.**

AM—A self contained loop antenna system is provided, which will give satisfactory reception on the standard broadcast band without requiring any additional external antenna. However, if stronger signals are desired from weak or distant stations an external antenna may be connected to the wire extending from the loop.

FM—A self contained line antenna system is provided for reception of stations appearing in the FM band. To use this line antenna a short wire jumper should be connected between the two outside screw terminals of the FM antenna panel, which is mounted on the broadcast loop antenna form. Should poor reception conditions make it necessary, an FM dipole antenna may be connected to the left hand and center screw terminals of the FM antenna panel. In such a case, the line antenna link should be disconnected.

AM Equipment:

Equipment Required:

- a) Broadcast Band Signal Generator.
- b) Output Meter.

1. Set band switch at AM. Advance volume control to full volume setting.
2. Connect output meter across voice control at points "E" and "F".
3. Connect the "high" side of the Signal Generator to point "A" through a .01 mfd condenser. Connect the "ground" side to point "B". Adjust the Signal Generator to 455 kc and with the receiver switched on, adjust the first and second I.F. transformers for peak output as shown on the output meter. The signal injected into the receiver should be as small in magnitude as possible, consistent with a useful deflection on the output meter.

VI. SERVICE ADJUSTMENTS:

This set has been designed to operate without an external ground, and the use of any ground connection is not recommended.

3. Power Connection.

After making certain that the power circuit is rated between 105 and 125 volts extend the line cord to its full length and insert the plug into the nearest convenient outlet. If the supply is DC, and the set fails to operate, it may be necessary to reverse the plug connection to secure operation of the set.

OPERATION:

The left hand knob controls the ON-OFF power switch and volume level. To turn receiver on, rotate this knob in a clockwise direction. Within a few degrees of rotation an audible click will be heard, and the dial will become luminous. After a half minute of warm up the receiver will be in an operating condition. Further advance of this control in a clockwise direction will provide an increase in volume level.

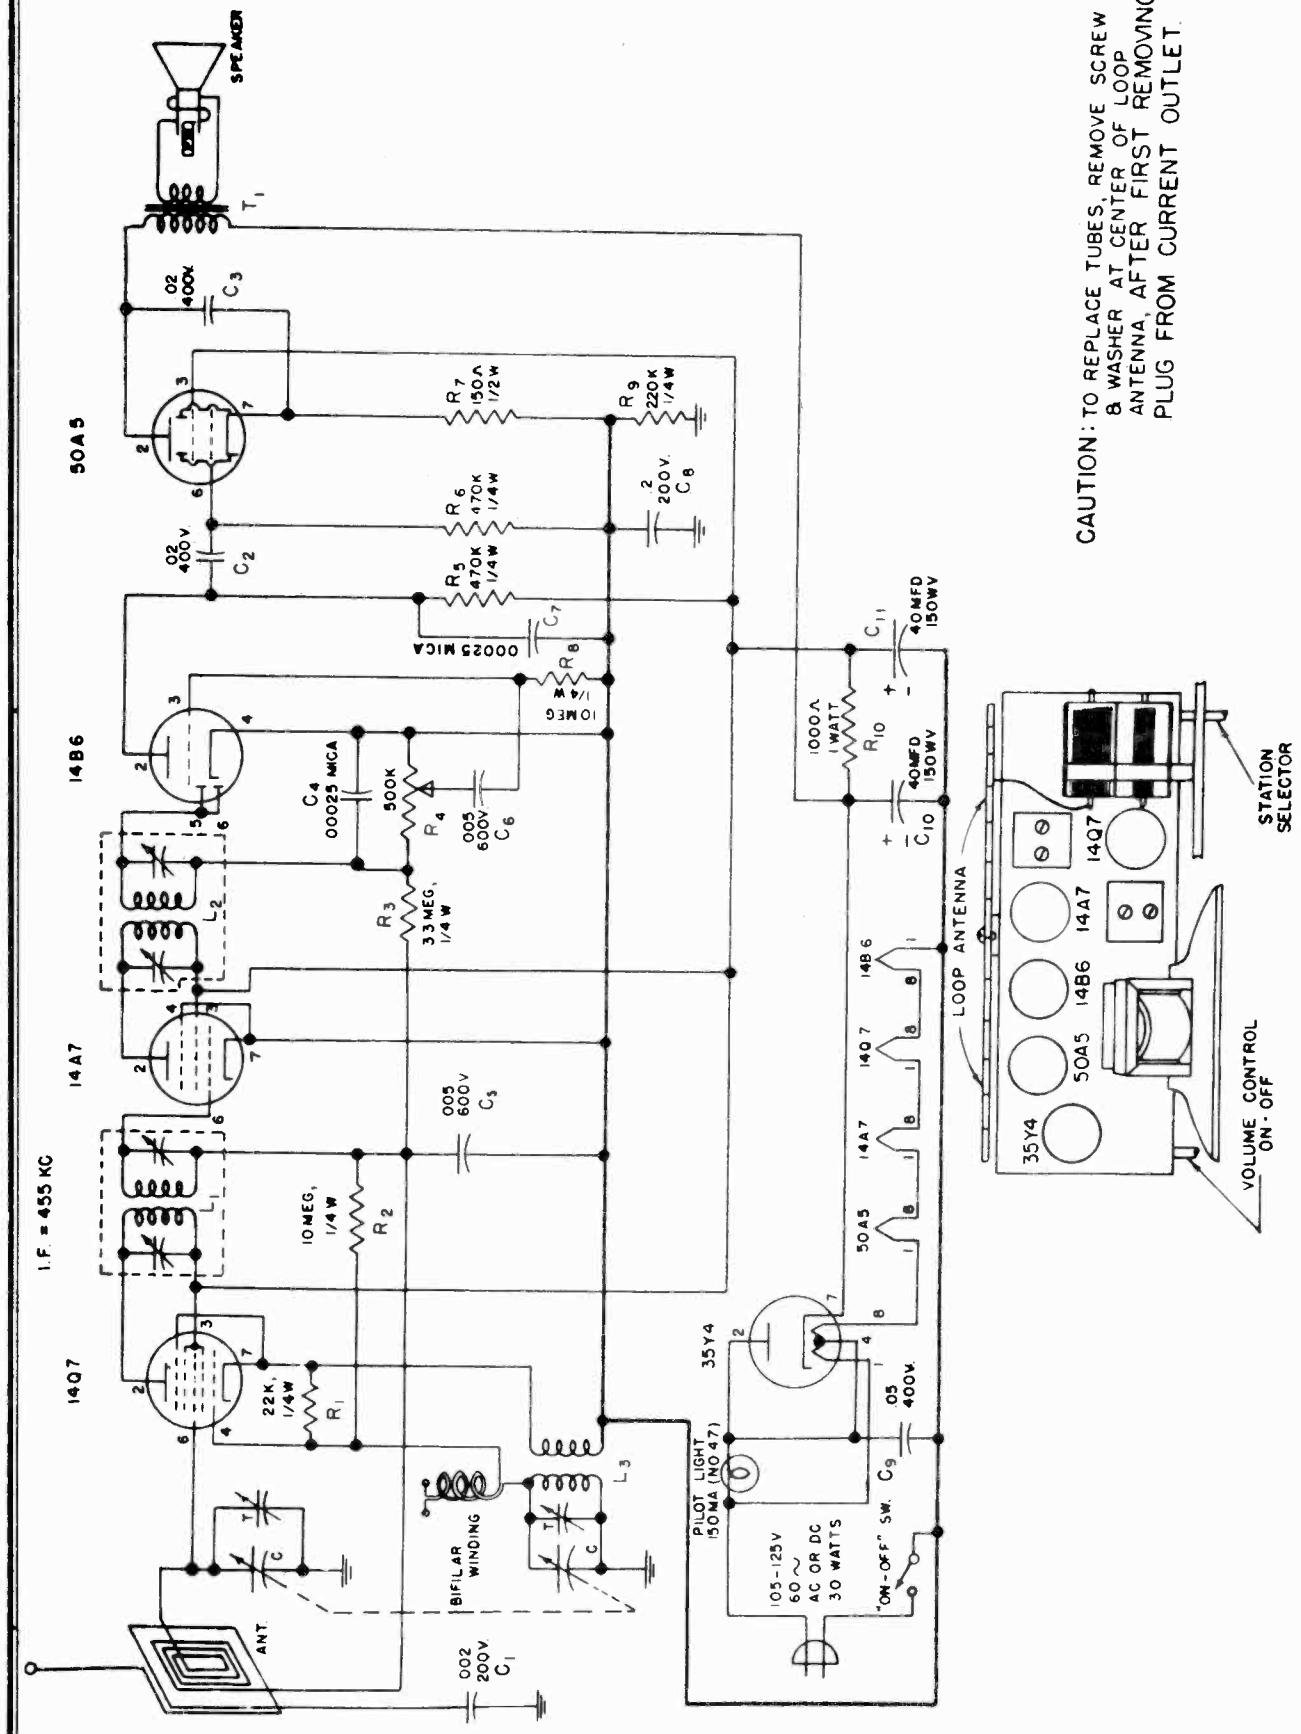

The center knob controls the selection of AM or FM stations. When rotated to the counterclockwise position, operation in the AM (standard broadcast) band is provided. When this control is rotated to the clockwise position, FM stations may be tuned in.

The right hand or tuning knob enables the selection of any desired station as indicated on the calibrated dial. The upper row of numbers is calibrated directly in megacycles and covers the FM band. The lower scale is used to tune in stations in the standard broadcast band. Add one zero to the numbers on this scale to obtain the station frequency in kilocycles.

VII. SERVICE ADJUSTMENTS:

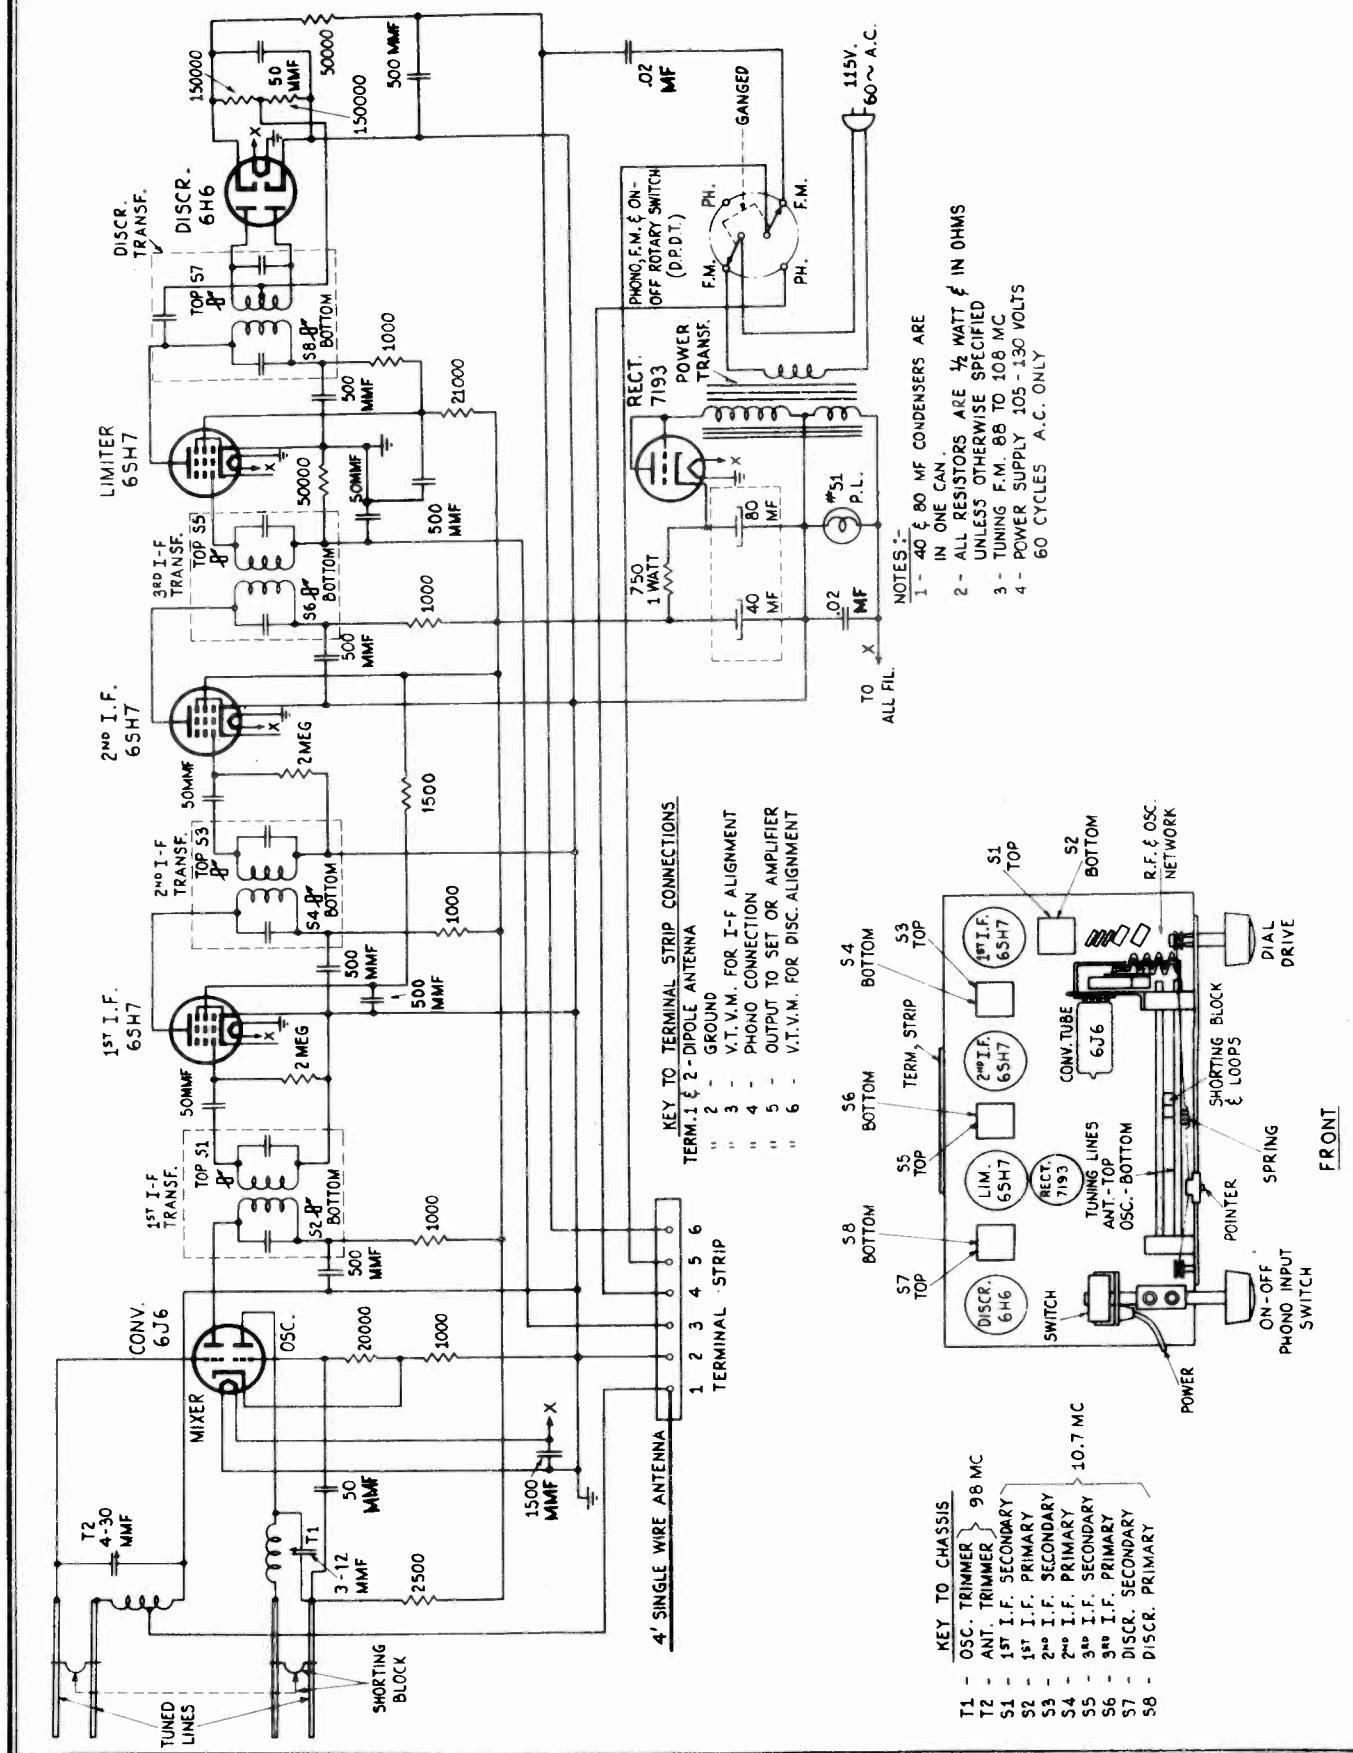

Alignment or adjustment of the various circuits of this receiver can only be made by a skilled radio technician with the proper equipment.

NOTE: Points A, B, C, D, E, and F are noted on the circuit diagram.

MODEL FIDELOTUNER
REVISED

F.M. SPECIALTIES, INC.

ALIGNMENT PROCEDURE

GENERAL NOTES

THE FIDELOTUNER SHOULD HAVE A WARMUP PERIOD OF ABOUT 30 MINUTES BEFORE ALIGNMENT PROCEDURE IS TO BE CARRIED OUT. IN ALL ADJUSTMENTS AN INSULATED ALIGNMENT TOOL IS TO BE USED. IF THE SIGNAL GENERATOR (USED IN EITHER THE METER OR VISUAL ALIGNMENT PROCEDURE) DOES NOT HAVE SUFFICIENT OUTPUT FOR AN INDICATION ON THE METER OR OSCILLOSCOPE WHEN THE OUTPUT OF THE GENERATOR IS FED INTO THE LIMITER OR THE LAST I-F AMPLIFIER THEN IT IS SUGGESTED THAT THE OUTPUT BE PLACED AT THE GRID INPUT TO THE R-F SECTION OF THE QJ6 CONVERTER AND THE REST OF THE ALIGNMENT PROCEDURE FOLLOWED AS IS. HOWEVER IF THE SIGNAL GENERATORS ARE CAPABLE OF STRONG SIGNAL OUTPUTS, THIS OUTPUT SHOULD BE JUST HIGH ENOUGH TO PRODUCE A DEFINITE INDICATION ON THE METER OR OSCILLOSCOPE.

I. METER METHOD OF ALIGNMENT

EQUIPMENT: A STANDARD SIGNAL GENERATOR CAPABLE OF FREQUENCIES ILLUSTRATED BELOW AND A VACUUM TUBE VOLTMETER (VTVM) AS AN OUTPUT INDICATOR. IF NO VTVM IS AVAILABLE USE AS HIGH A RESISTANCE PER VOLT DC VOLTMETER (PREFERABLY 20,000 OHMS PER VOLT METER). THE LOW SIDE OF THE SIGNAL GENERATOR AND METER SHOULD BE CONNECTED FOR ALL ALIGNMENTS TO CHASSIS GROUND OR PIN 2 OF THE TERMINAL STRIP.

STEPS	TUNER DIAL SETTING	SIGNAL GENERATOR FREQUENCY	CONNECT SIGNAL GENERATOR TO	DUMMY ANTENNA	METER CONNECTION	ADJUST TRIMMERS OR COILS IN ORDER SHOWN	REMARKS
A	HIGH FREQ. END OF BAND	10.7 MC UNMODULATED	PIN 4 GRID OF 6SH7 2ND IF AMPLIFIER	0.02 MF	TO PIN 3 OF TERMINAL STRIP	S5, S6	MAXIMUM DEFLECTION ON METER
B	"	"	PIN 4 GRID OF 6SH7 1ST IF	"	"	S3, S4	" " " "

F	TUNE DIAL FOR MAXIMUM METER DEFLECTION	90 MC UNMODULATED	"	"	"	OSCILLATOR COIL	IF DIAL READING IS TOO LOW ACCORDING TO THE FREQUENCY OF THE GENERATOR EXPAND OSCILLATOR COIL SLIGHTLY; IF DIAL READING IS HIGH, THEN COMPRESS COIL. IN EITHER CASE IT IS FOR MAXIMUM DEFLECTION. REPEAT STEPS E AND F FOR BEST POSSIBLE INDICATION.
G	REPEAT STEP D FOR FINAL ADJUSTMENTS OF R-F AND OSCILLATOR SECTIONS						
H	HIGH FREQ. END OF BAND	10.7 MC UNMODULATED	PIN 4 GRID OF 6SH7 LIMITER	0.02 MF	TO JUNCTION OF R11 AND R12 DISCRIMINATOR LOCAL RESISTORS	S8	MAXIMUM DEFLECTION ON METER
I	"	"	"	"	TO PIN 6 OF TERMINAL STRIP	S7	ZERO DEFLECTION (ZERO READING)* ON METER

*VARY SIGNAL GENERATOR BY A SIMILAR AMOUNT ON EITHER SIDE OF THE 10.7 MC SIGNAL AND OBSERVE METER. THE READINGS SHOULD BE THE SAME BUT OF OPPOSITE POLARITY. IF THEY ARE NOT, REPEAT STEPS H AND I IN THE ORDER INDICATED.

II. VISUAL METHOD OF ALIGNMENT

EQUIPMENT: OSCILLOSCOPE AND ANY GOOD STANDARD FM SIGNAL GENERATOR CAPABLE OF FREQUENCIES AND LEVELS LISTED BELOW. THE OUTPUT FREQUENCY OF THE SIGNAL GENERATOR WILL ALWAYS BE FREQUENCY MODULATED. THE LOW SIDE OF THE SIGNAL GENERATOR AND OSCILLOSCOPE HORIZONTAL AND VERTICAL TERMINALS SHOULD BE CONNECTED FOR ALL ALIGNMENTS TO CHASSIS GROUND OR PIN 2 OF THE TERMINAL STRIP. THE MODULATING SIGNAL FROM THE F-M SIGNAL GENERATOR SHOULD, FOR ALL ALIGNMENTS BE ATTACHED TO THE HORIZONTAL TERMINAL OF THE OSCILLOSCOPE.

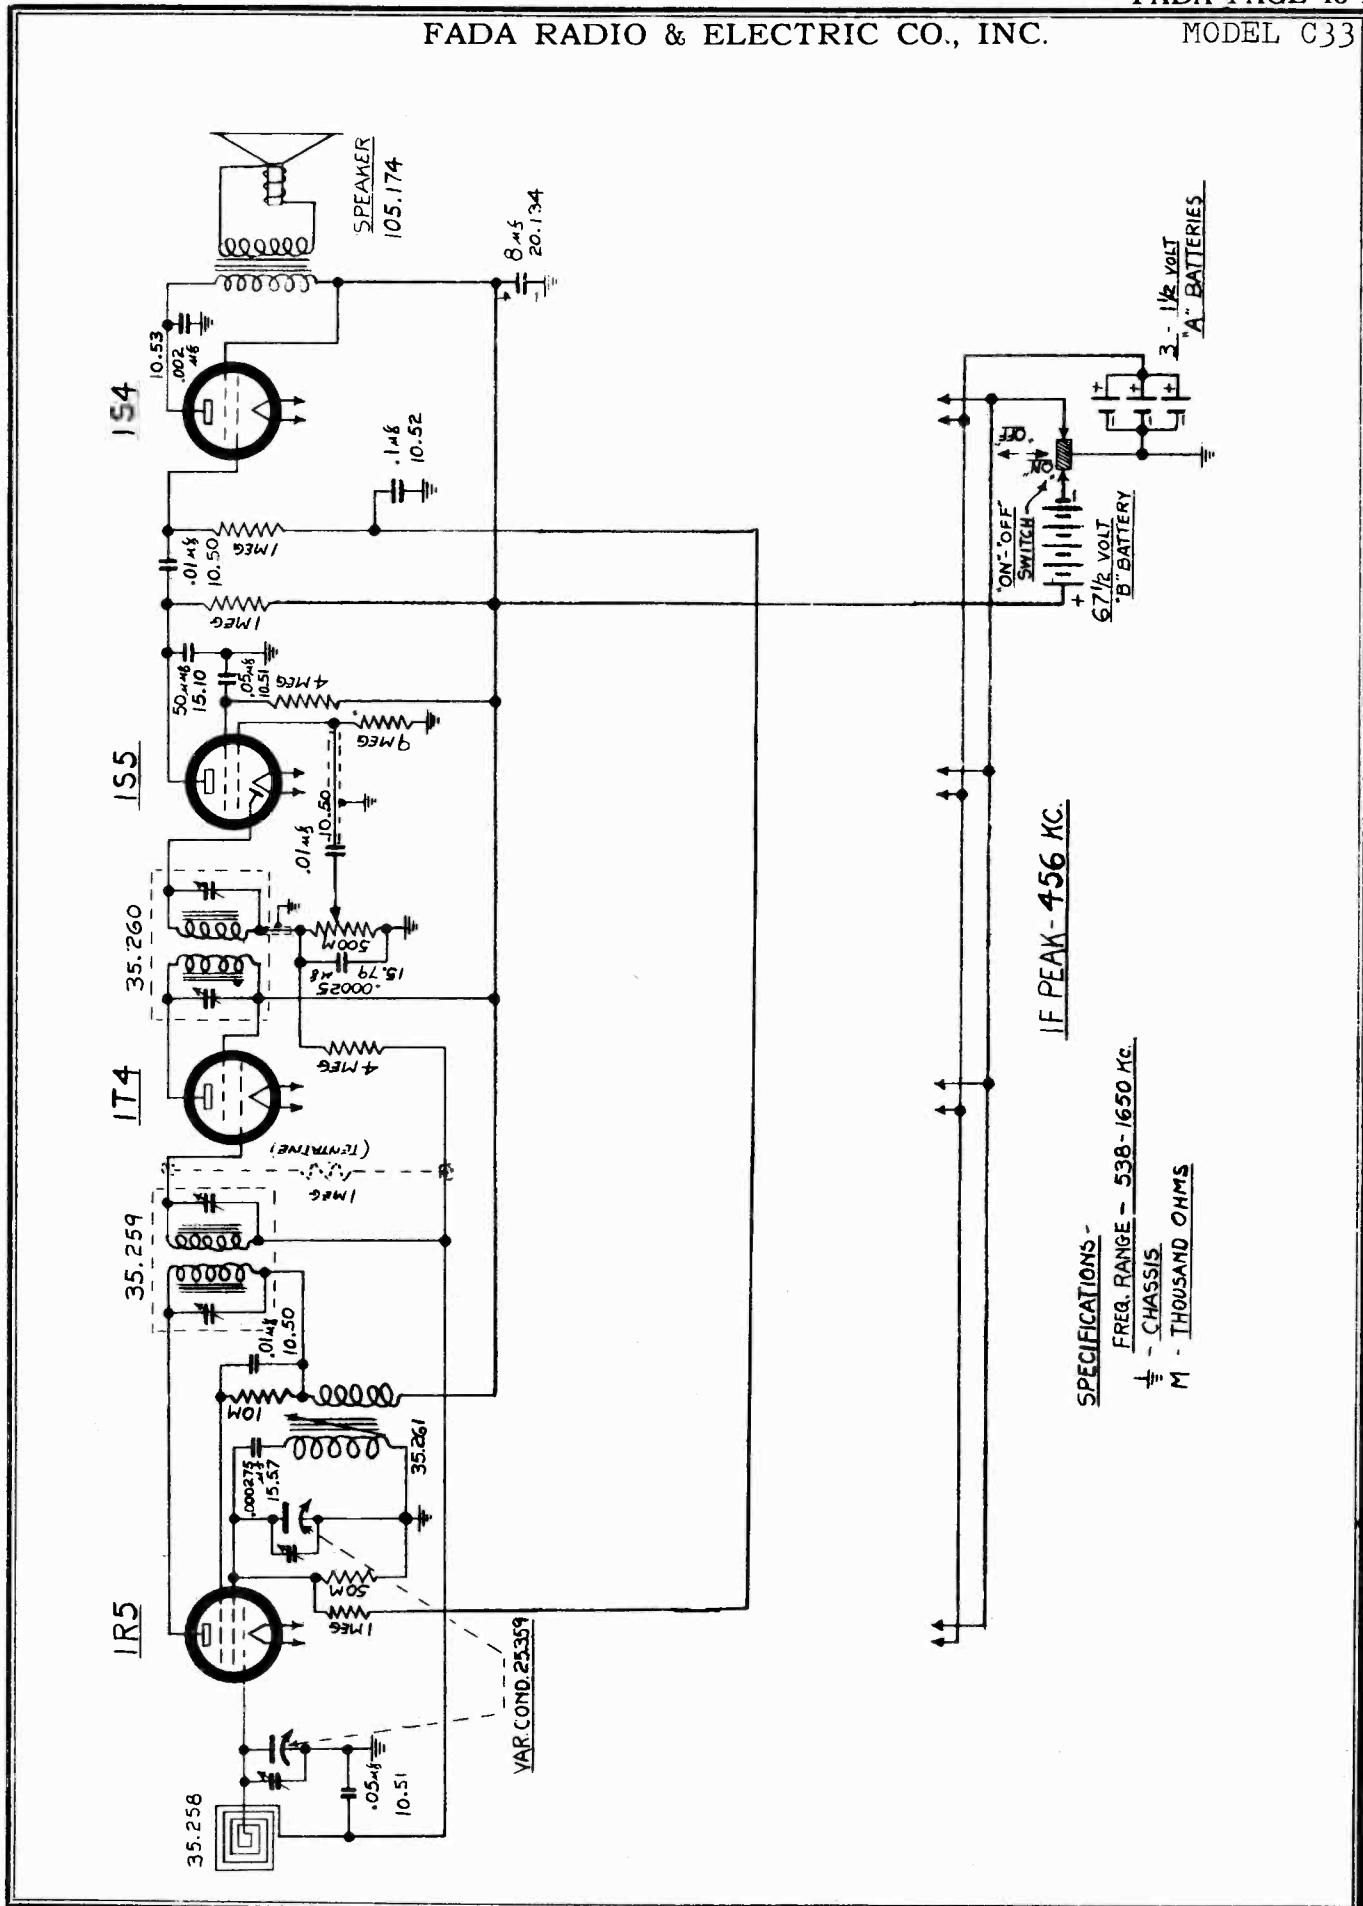

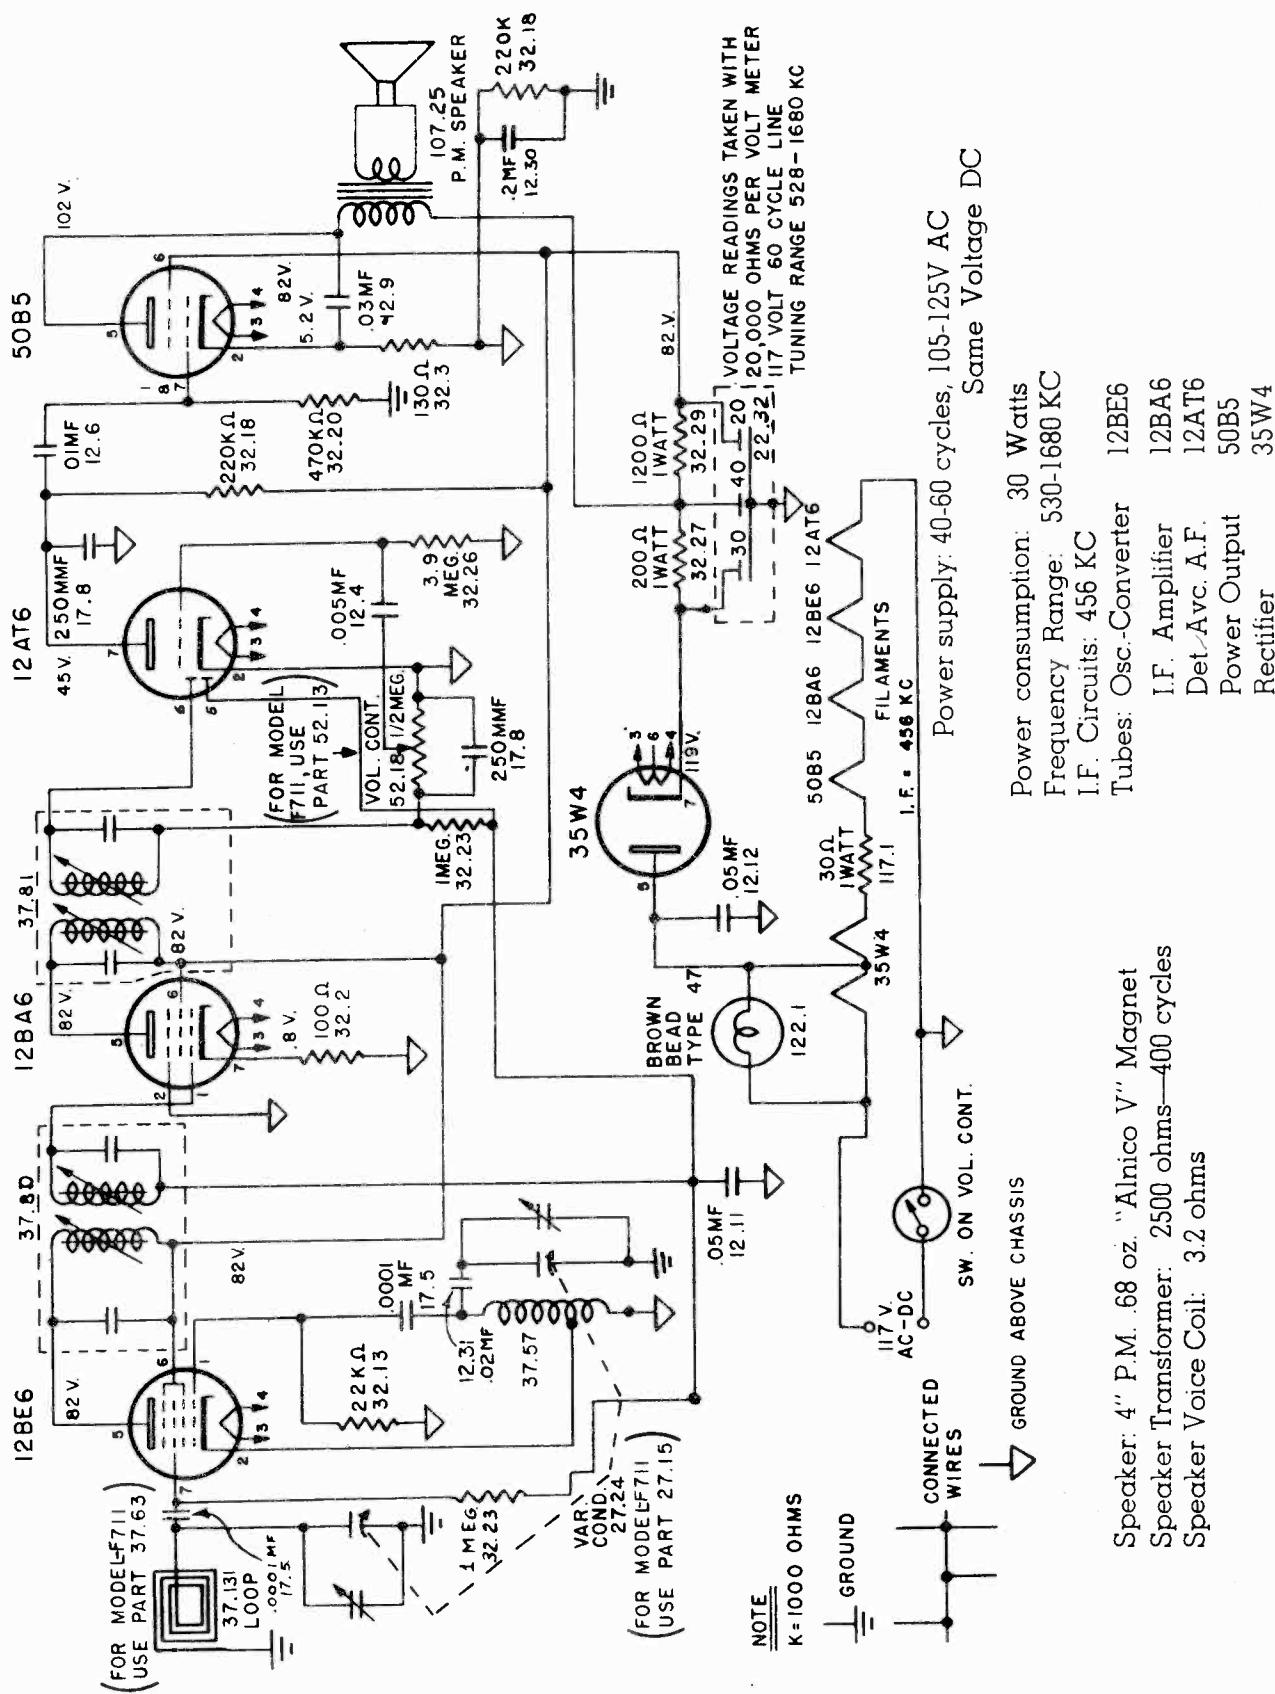

PATTERN A

PATTERN B

STEPS	TUNER DIAL SETTING	SIGNAL* GENERATOR FREQUENCY AND DEVIATION SETTING	CONNECT SIGNAL GENERATOR TO	DUMMY ANTENNA	METER CONNECTION	ADJUST TRIMMERS OR COILS IN ORDER SHOWN	REMARKS

*IF THE F-M SIGNAL GENERATOR CANNOT PRODUCE THE FREQUENCY DEVIATION (i.e., SWEEP FREQUENCY) INDICATED THEN THE LARGEST FREQUENCY DEVIATION THAT THE GENERATOR CAN PRODUCE SHOULD BE USED.

ALIGNMENT PROCEDURE

No attempt should be made to realign the various circuits until all other causes have been checked, unless the condition is so obvious as to indicate that realignment is necessary. Then proceed as follows:

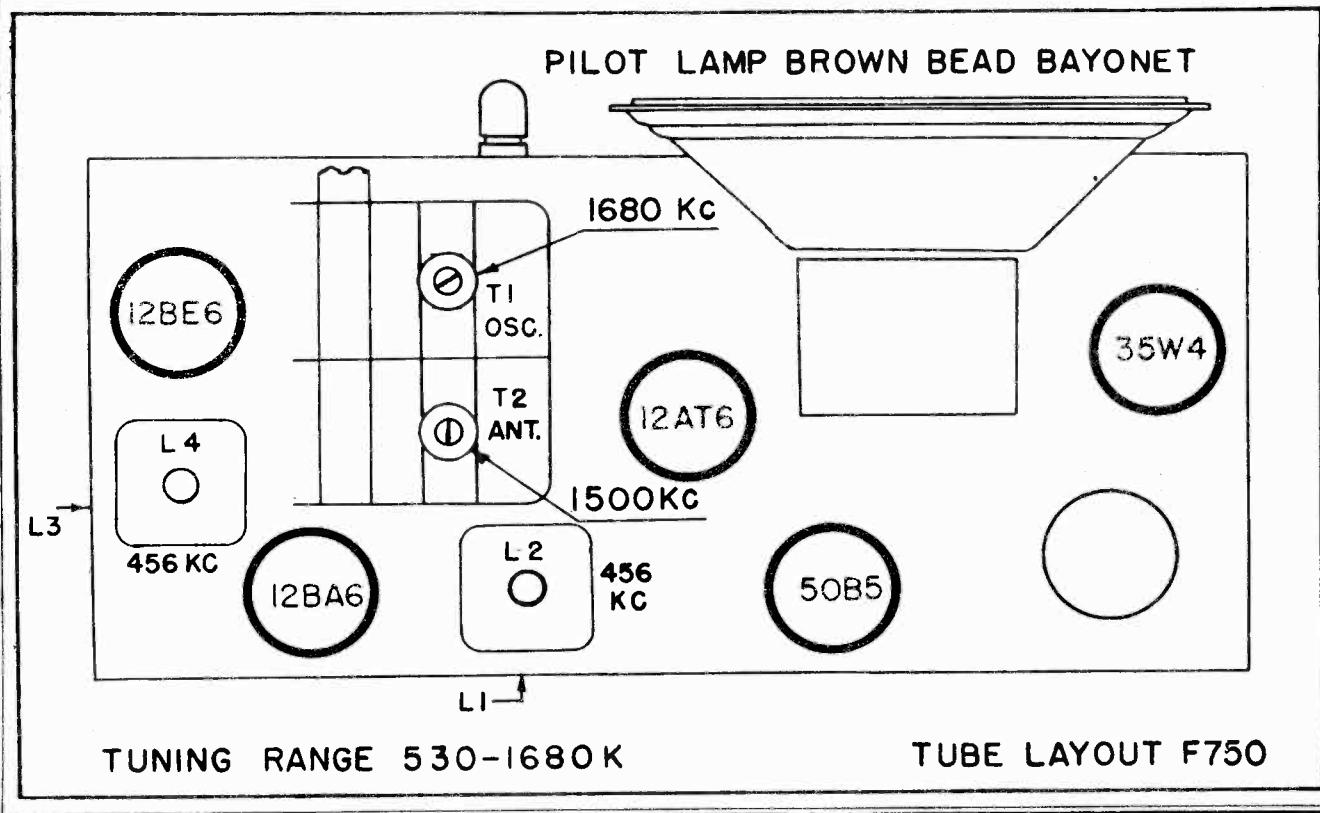

Volume Control full on.

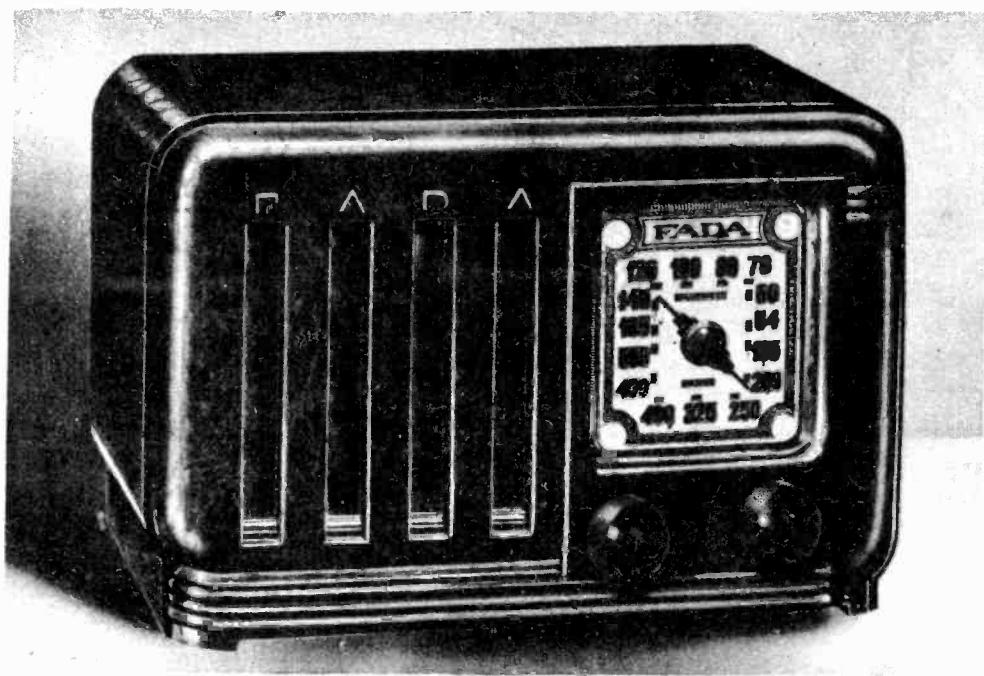

Low range A.C. meter connected across voice coil to indicate output.

Keep signal generator attenuated so as to maintain 1/2 scale reading on output meter.

Make certain that dial pointer is exactly horizontal when variable condenser is fully meshed.

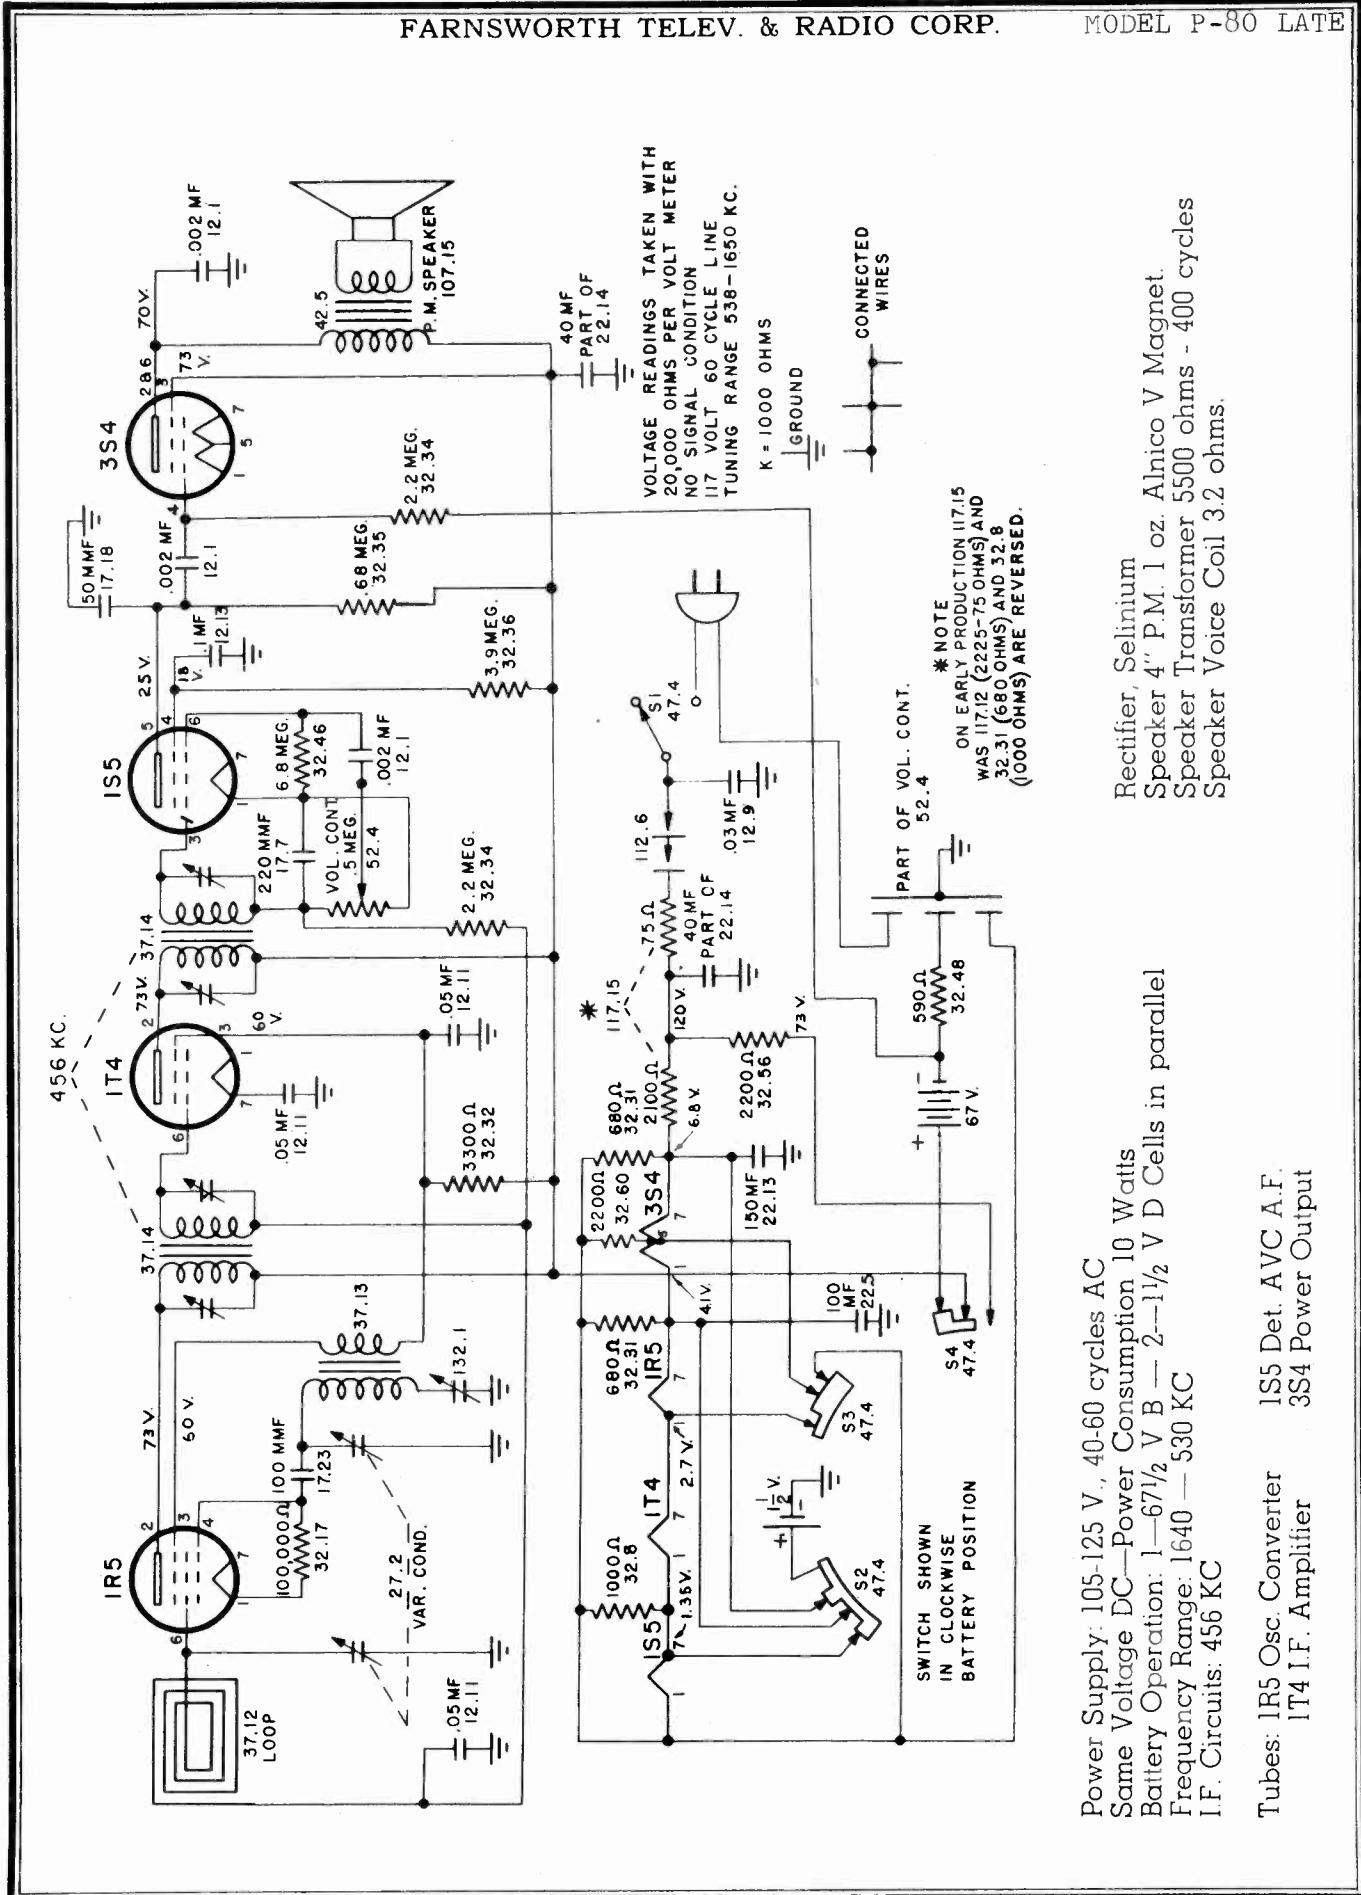

Receiver Dial at:	Signal Generator	Dummy Antenna	Connect Signal Generator to:	Refer to Chassis Layout for Location of Trimmers
1 Full Open	Exactly 456 KC	.1 MF	Control Grid 12BE6 Tube (Top) Rear Section Variable Condenser	Adjust for Maximum Output L1, L2, L3 & L4

ALIGNMENT PROCEDURE

No attempt should be made to realign the various circuits until all other causes have been checked, unless the condition is so obvious as to indicate that realignment is necessary. Then proceed as follows:

Disconnect Loop leads—Remove Chassis from Cabinet.

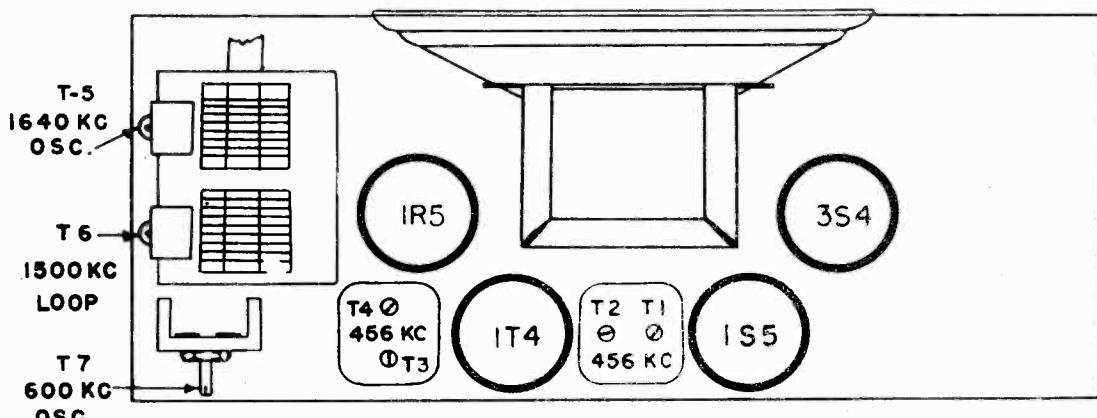

Volume Control full on.

Low range A.C. meter connected across voice coil to indicate output.

Keep signal generator attenuated so as to maintain $\frac{1}{2}$ scale reading on output meter.

Use battery power when available.

Receiver Condenser at:	'Signl Generator	Dummy Antenna	Connect Signal Generator to:	Refer to Chassis Layout for Location of Trimmers
1 Fully closed	Exactly 456 KC	.1 MF	Chassis Ground and Control Grid 1R5 Rear Section Var. Cond.	Adjust for maximum output T1, T2, T3, and T4.
2 Fully closed	Approx. 538 KC	.1 MF	"	Adjust for maximum output T7
3 Fully open	Exactly 1640 KC	.1 MF	"	Adjust for maximum output T5
Repeat Operations 2 and 3.				
The next two operations are performed with the chassis in the cabinet, the loop connected and tuning indicator in position.				
4 Approx. 1500 KC	Approx. 1500 KC		Radiating Loop 20" from Receiver	Adjust T6 for maximum output.
5 Approx. 600 KC	Approx. 600 KC		Radiating Loop 20" from Receiver	Adjust T7 for max. while rocking variable cond.

CHASSIS LAYOUT

DIAL STRINGING

ANTENNA AND OSCILLATOR COILS

EQUIPMENT AND PROCEDURE FOR ALIGNMENT

An output meter and a signal generator are required for proper alignment of these sets. The signal generator should be calibrated at the following points: 455 Kc., 600 Kc., 1000 Kc., 1500 Kc., 3.5 Mc., 7.5 Mc., 9.5 Mc. and 20 Mc. All adjustments should be made with the volume control set for maximum, keeping the signal generator output as low as possible to prevent AVC action and incorrect settings.

Connect the low side of the signal generator to the ground terminal on the chassis. Connect the high side of generator to antenna terminal through dummy load of 200 MMF for broadcast band and a dummy load of 400 ohms for shortwave.

STEPS	DUMMY ANTENNA	SET GENERATOR AT	SET GANG AT	ADJUST	LOCATED	TO OBTAIN	MAXIMUM OUTPUT

50 Cycle operation of changer requires modification

INSTRUCTIONS FOR ALIGNMENT OF FM BAND

1. Necessary Equipment:

RF Signal Generator, Vacuum Tube Voltmeter,
Insulated Screw Driver.

NOTE—All alignment should be done with only sufficient signal amplitude to provide satisfactory signal to noise ratio, and readable output on output meter. The use of excessively strong signal is almost certain to produce misalignment.

2. Procedure for IF Alignment, FM Band

- Connect V.T.V.M. from ground to audio lead of ratio detector (discriminator). Connect generator tuned to 10.7 mc. to grid of third FM IF tube through 0.1 MFD capacitor.
- Turn secondary slug of ratio detector transformer (bottom) out as far as it will turn.
- Tune primary for maximum output.
- Connect generator to the grid of first FM IF tube.
- Turn bottom slug on second FM IF transformer out as far as possible. Tune primary for maximum output. Secondary may now be tuned for maximum.
- Connect generator to the grid of first FM IF tube.
- Turn bottom slug on second FM IF transformer out as far as possible. Using slug number 2, tune primary for maximum out. Tune secondary for maximum, using slug number 4 (bottom).
- Connect generator to converter grid through 10,000 ohm resistor and 0.1 Mfd capacitor.
- Follow same procedure given in paragraph (g), substituting first FM IF transformer in lieu of second IF transformer.
- Tune secondary (bottom slug) of ratio de-

MODELS K-084,
-086, -287, P

tector transformer for zero or minimum output.
k. The FM IF system should be aligned if instructions have been carefully pursued.

3. Instructions for Aligning FM RF Channel

- Equipment required: RF Signal Generator, Range 88 to 106 Mc., Output Meter, Insulated Screw Driver.
- Connect RF signal generator in series with 300 ohm carbon or metalized resistor to "high" side of FM antenna socket. Connect output meter across voice coil of speaker.
- Set tuning control for pointer to calibrate at the equivalent of half way between channels 280 and 300.
- Apply 106 Mc. signal.
- Set converter and antenna trimmers at minimum capacity.
- Adjust oscillator by changing physical location of 9 mmf ceramic capacitor until signal is heard at maximum output.
- Adjust antenna and converter trimmers for maximum output.
- Set tuning controls so that dial pointer calibrates at the pointer's width higher than channel 220.
- Apply 92 Mc. signal.
- Adjust oscillator slug until signal is heard. Adjust converter and antenna slugs to maximum output.
- Repeat operations c to j inclusive.

NOTE—The degree of adjustment required in the tuning of the oscillator slug will determine the number of times operations c to j must be repeated until no further gain in sensitivity is obtained.

- Carefully tune across the entire FM band for the observance of dead or weak spots that may be a result of improper alignment or defective components. This can be determined by carefully noting the degree of receiver hiss in the absence of a received signal.

ALIGNMENT INSTRUCTIONS FOR AM BAND

EQUIPMENT REQUIRED

For proper alignment, a calibrated signal generator having fundamental frequencies from 455 Kc to 1500 Kc should be provided.

The indicating device for showing correct alignment may be a high resistance AC voltmeter or a vacuum tube voltmeter.

Connect the AC voltmeter either across the voice coil of the loud speaker, or if the meter range is high enough, to the plate in the output stage (through a condenser [0.1 Mfd.] to keep the DC out of the meter).

Maintain the output of the signal generator as low as possible to prevent AVC action and false settings.

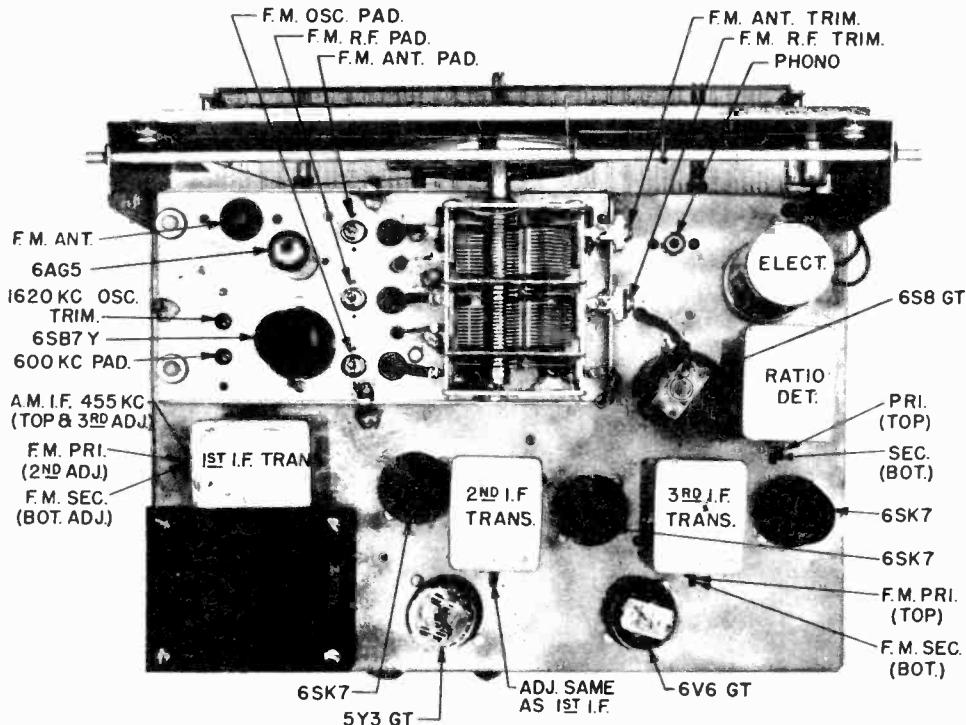

TABULATION FOR AM ALIGNMENT

STEPS		CONNECT GENERATOR	SET GENERATOR AT	SET GANG AT	ADJUST	TO OBTAIN	
1		Set tone and volume controls at maximum					
2	Through 1 Mfd.	Sig. Grid (pin 8) Conv. Tube	455 Kc	Quiet Point	2nd IF Slugs # 1 and 3	MAXIMUM OUTPUT	
3					1st IF Slugs # 1 and 3		
4	Through 200 mmf	External Antenna Post on Loop	1500 Kc	1500 Kc	BC Osc. Trimmer		
5			600 Kc	600 Kc	Osc. Padder*		
6	Through 1 Mfd.	Check dial calibration at several frequencies. If not reasonably correct, adjust oscillator padder. See note 1.

CIRCUIT MODIFICATION

Early sets did not incorporate the coil-condenser combination connecting between the plate of the RF amplifier and the grid of the converter. Below is an excerpt indicating that portion of the schematic of the early-production receiver.

Dial Stringing Diagram

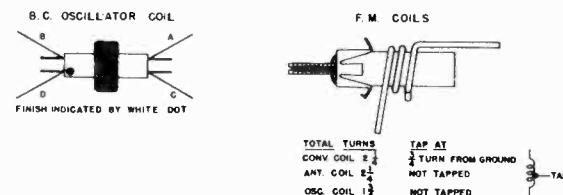

The GK-080 series instruments incorporate two internal antennas; a loop antenna used in broadcast band reception and a folded-dipole antenna used for FM reception.

These internal antennas are intended for use only in the presence of adequate field strength, as in large metropolitan areas where local stations supply the majority of desired programs. Neither a loop nor a dipole element which is within the confines of the cabinet can be considered as efficient signal pickup devices and, should field strength requirements be not fulfilled, it will be necessary, for satisfactory reception, to install an efficient outside folded dipole antenna which feeds the receiver through a 300 ohm transmission line.

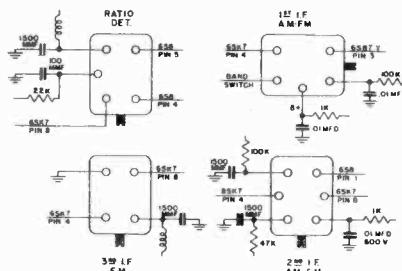

Both the loop and the dipole (internal or external) antennas exhibit certain characteristics of directivity, with which the experienced serviceman is familiar, which should be borne in mind when locating the receiver (or external antenna) in the home. Slight orientation of the receiver may effect more satisfactory reception of desired weak signals.

MULTIPLE RESPONSE AND WHISTLES

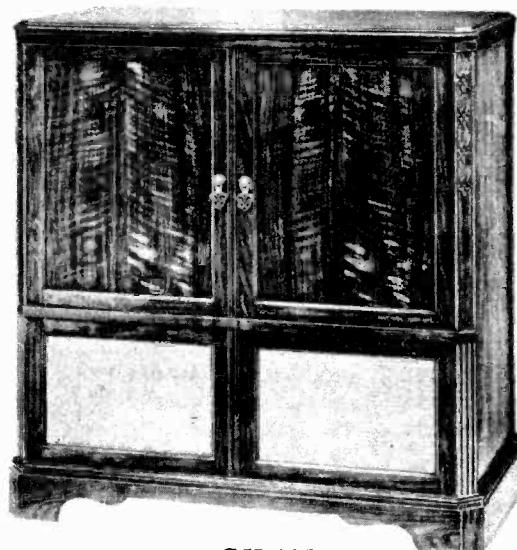

In metropolitan areas with close proximity to several strong transmitting stations, it may be necessary, on early production receivers, to connect a 200 mmf mica capacitor across the wave trap. This must be placed on the band switch so it is switched out on FM. Should oscillation on low end of the band be experienced in the GK-084 (chairside) instrument, it is recommended that a modified wave trap (part No. 38930) be substituted for wave trap connected between ground and terminal C1 of Section 2, front, of band switch.

GENERAL DESCRIPTION

SECTION 2

This Maintenance Manual is intended to assist the serviceman in understanding and adjusting for proper operation of the Capehart, Panamuse N series instruments. No attempt has been made toward a theoretical analysis of the various electrical and mechanical functional parts, for it is assumed that none but qualified technicians shall attempt adjustments.

An entirely new instrument, in most respects, is this first post-war product of Capehart. Cabinets remain the authentic styling that was offered pre-war and basic principles of the 16-E changer are yet unique but otherwise, little semblance is seen to the previous De-Luxe Capehart. This change has been brought about largely by new standards of dependability and excellence, particularly as concerns the tuner-amplifier-speaker combination, established in the many military applications of communications equipment.

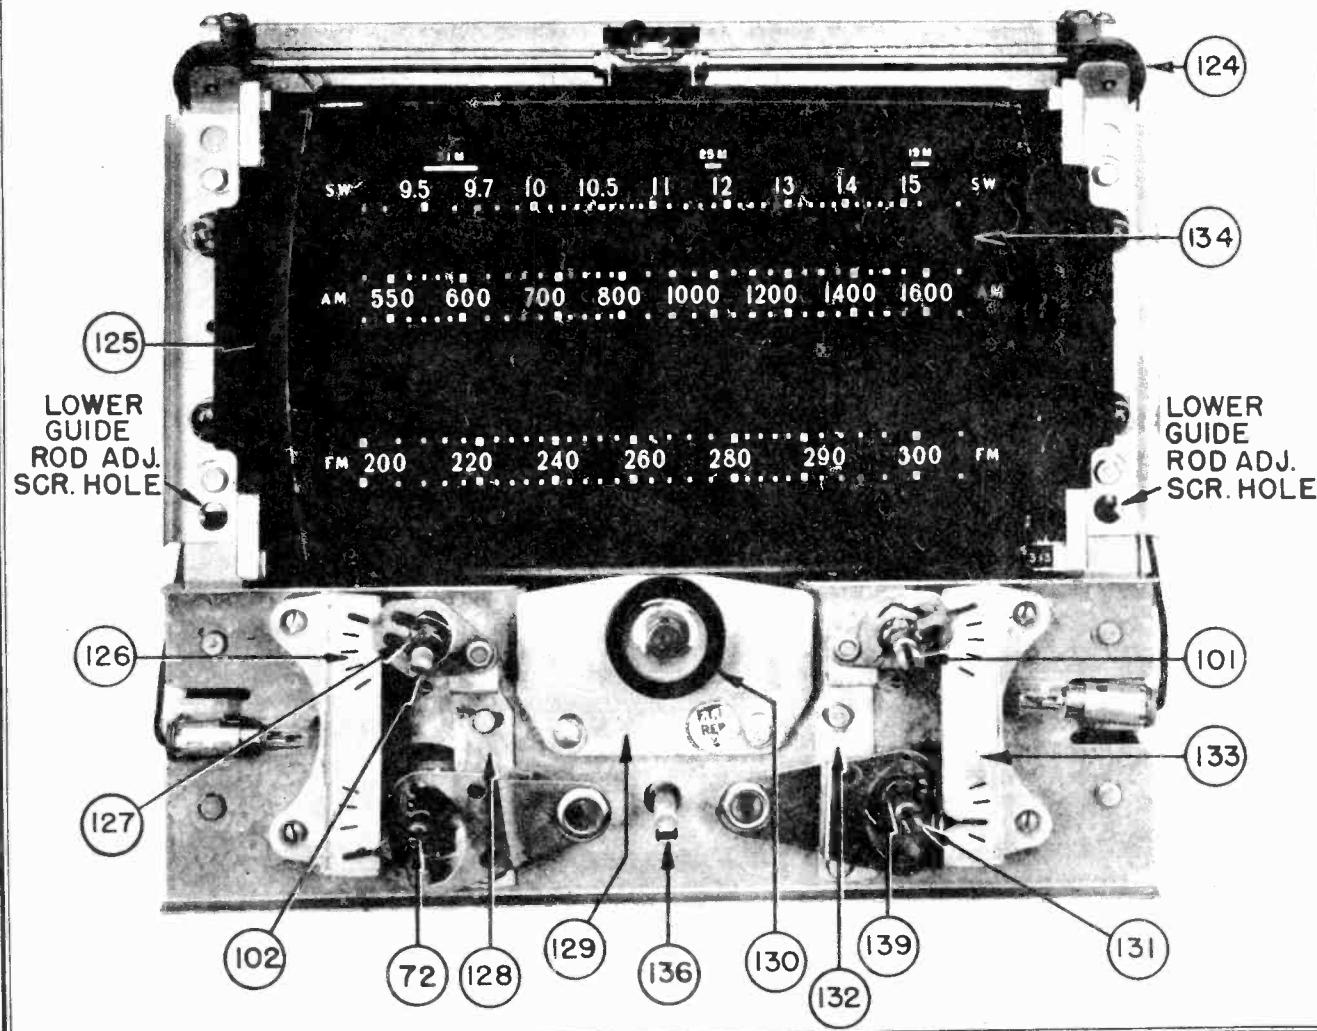

In specifically enumerating these outstanding features and advancements, the several portions of the instrument shall be considered individually.

SECTION 3

THE RADIO TUNER

Those servicemen who dealt with the war-time application of communications equipment will readily recognize "the military" in the radio tuner. Paint over the cadmium chassis plating, bathtub-type oil-filled condensers, strip-mounting of small parts and extensive cabling are all new innovations which were basic to the armed forces' equipment. Other features also contribute to make this chassis, we believe, electrically and mechanically a masterworks:

- A. Completely separate FM-AM circuits up to entry into the audio system, leading to maximum efficiency in each circuit.
- B. Copper FM tuning condenser plates, rubber-mounting of R-F assembly reduce microphonics.
- C. R-F sub-assembly at the rear of chassis, easily removable for service.
- D. Miniature tubes are employed in the FM R-F section for optimum performance in the 100 mc. range of FM.

FARNSWORTH TELEV. & RADIO CORP. MODELS CAPEHART,
PANAMUSE N SERIES

E. Negligible thermal effects in high frequency circuits. Low-drift ceramic condensers, temperature-compensation condensers, silver-plated invar wire to form the oscillator coil and polystyrene coil forms all contribute to frequency stability.

F. Adjustments for accurate tracking calibration. Adjustments are made to inductance, as well as capacity of tracking circuits—a feature usually to be had only in high-grade communications-type equipment.

G. Separate AM antenna coil and selector switch for use of either a loop or an external antenna.

H. Slug-tuned IF transformers and large capacity across tube input afford a high degree of stability. Changing of tubes and the "Miller effect" (a change of tuning under varying AVC potential) produce no detuning.

I. Quarter-wave resonant lines for FM RF circuit elements, accomplish image rejection of 100 decibels—a phenomenally high figure.

J. Cathode degeneration in IF stages enhances stability.

K. Ratio FM detector discriminates against AM (noise), particularly at low signal levels where the discriminator-limiter combination fail. Increased output also allows less gain in IF amplifier, effecting greater stability.

L. No critical wire placement. Detuning is practically impossible as a result of wire misplacement.

M. Improved tuning-eye circuit, showing proper tuning of FM, as well as AM.

N. Low impedance output stage. A cathode-follower provides an output of less than 500 ohms impedance. High frequencies are therefore not attenuated in the inter-chassis connecting line.

O. Reduced potential on those pilot lamps which necessitate chassis-removal for replacement. Lamp life-expectancy in excess of 10,000 hours—probably the life of the instrument.

P. Travel-light dial. By optically projecting a line of light upon the glass face, parallax is wholly eliminated. Positive band-indication is also thereby had.

These enumerate but major features of the tuner. Others, such as separate decoupling R-C networks for each stage, separate bass and treble controls, FM calibration to the new FCC channel assignments are apparent from inspection of the set and schematic. Neither esthetic appeal nor electrical efficiency have been neglected or compromised.

SECTION 4 AUDIO AMPLIFIERS

A portion of the audio system is incorporated in the tuner chassis. This is a 6SN7 tube, one section of which serves as an amplifier, the second section being used as a cathode-follower for low-impedance output. In addition, a 6J7 (triode-connected) gives added amplification in the "phono" position only.

Outstanding features of the amplifier chassis are:

A. N-1 amplifier: Individual output tube bias and hum-bucking adjustment. **N-2 amplifier:** Inverse feedback affords low distortion at high power levels.

N-1 and N-2 amplifiers:

B. Very low inter-modulation distortion.

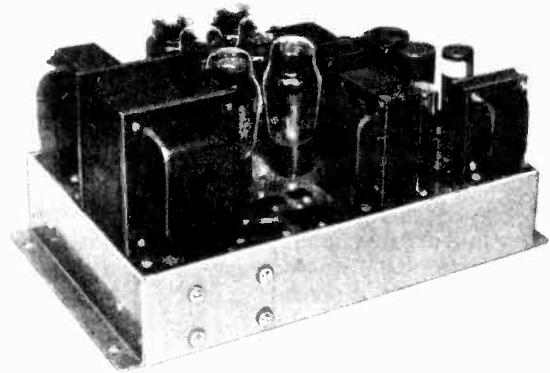

Compensation of deficiencies in one amplifier stage may be made in another stage. Such a practice however, gives rise to intermodulation or "cross-talk," resulting in the production of new and unwanted frequencies. This effect, often overlooked in amplifier design, has here been given particular attention, such distortion being held to less than one-half of one per cent.

C. Frequency response uniform from 50 cycles to 12,000 cycles per record.

D. Gain control in amplifier permits any "reference level" setting of the tuner-chassis control.

E. Auxiliary input provides for the use of wire recorder or other signal source.

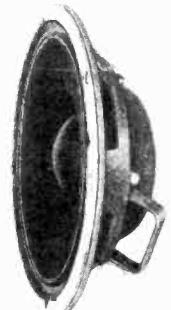

F. Fuses in both primary of transformer and output of rectifier, affording complete transformer-rectifier protection.

G. Resistor in —B lead to avoid shock. To prevent hum pickup in the power cable, grounding between the two chassis is made through the audio cable. Should this cable be removed, there remains 33 ohms between chassis, maintaining continuity and preventing high electrical potential between chassis.

SECTION 5 SPEAKERS

400N Series Instruments. The single speaker in the 400N Series instruments results from military-sponsored design to produce the finest of sound-reproducing units. This speaker, exclusively used for home-reproduction in The Capehart, is in reality a 2-cone unit for high-fidelity response to both high and low frequencies. Both cones are driven by a 4-inch voice coil of 4 ohms impedance, a helix of spirally-wound copper ribbon, operating in the intense magnetic field produced by 5 pounds of alnico metal. Its power capacity is in excess of the thirty watts delivered by the N-1 amplifier.

For proper frequency response, the speaker must be contained within a full enclosure of volume not less than 2½ nor more than 4 cubic feet, having firmly attached a lining of suitable absorbent material such as hair-felt.

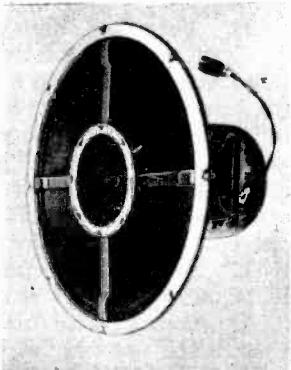

MODELS CAPEHART, FARNSWORTH TELEV. & RADIO CORP.

PANAMUSE N SERIES

N Series Instruments

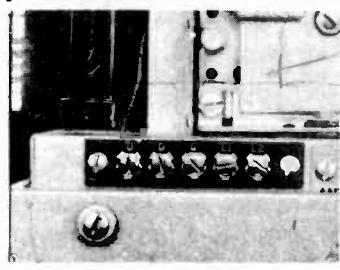

Instruments. Although but a single mounting is required for the reproducing unit of the 100-Series instrument, it consists of 2 speakers coaxially-mounted. One, with 15-inch cone, is responsive to low frequencies while the other, a 5-inch unit, acts as high-frequency reproducer. Both are field-excited by heavy alnico permanent magnets. Such a "woofer-tweeter" combination has long been accepted in high-fidelity sound reproduction since but a single cone is incapable of proper response to both low and high-frequency electrical impulses.

The combined voice-coil impedance of the 2 units is 8 ohms.

SECTION 7 ANTENNAS

Capehart N-series instruments incorporate 2 internal antennas; a loop antenna used in broadcast-band reception only and a folded-dipole antenna used for FM reception. The latter is also, as a straight-wire antenna, employed in short-wave reception, and, if desired, in broadcast reception. This latter function is accomplished by a switch at the rear of the chassis.

These internal antennas are intended for use only in the presence of adequate field strength, as in large metropolitan areas where local stations supply the majority of desired programs. Neither a loop nor a dipole element which is within the confines of the cabinet can be considered as efficient signal pickup devices and, should field strength requirements be not fulfilled, it will be necessary, for satisfactory reception, to install an efficient outside folded dipole antenna which feeds the receiver through a 300 ohm transmission line.

Both the loop and the dipole (internal or external) antennas exhibit certain characteristics of directivity, with which the experienced serviceman is familiar, which should be borne in mind when locating the receiver (or external antenna) in the home. Slight orientation of the receiver may effect more satisfactory reception of desired weak signals.

An external folded-dipole antenna will, of course, afford optimum signal pickup on FM or short-wave AM and, when the rear-chassis switch is at the "antenna" position, it will provide a good external "flat-top" for broadcast-band reception.

The internal loop antenna connects to terminals L1, L2 of the rear-chassis terminal strip; the internal or external folded-dipole antenna connects to terminals D, D on the same strip—both without regard to polarity. Terminal "G" is the connection to an earth ground.

SECTION 8

SETTING UP FOR OPERATION

We cannot overemphasize the necessity for more than a perfunctory check of the instrument prior to demonstration on the dealer's floor or to installation in the home. Improperly installed or improperly operating when installed, extra service costs and customer dissatisfaction rise rapidly, overshadowing the short added time necessary to a thorough checking routine. At least the following items should be covered and if you are thorough in your work, you undoubtedly will make additions to the list.

SUGGESTED INSPECTION ROUTINE FOR THE CAPEHART INSTRUMENTS

1. Unpacking. Carefully remove the instrument from its shipping case.
2. Inspect condition of cabinet. Packing case should be scrutinized. If panel is broken, look for concealed damage—if cabinet is damaged by rough handling in transit, concealed damaged claim should be filed with the "carrier."
3. See that all shipping tie-downs are removed from back of magazine, reverse-arm guide, tone-changer-arm and swing lever and that the cardboard block is removed from under the reverse arm lock. It is important that the reverse-arm lock be checked to see that it is not caught behind the stop, which would cause the changer to jam when started. To release such a jam, remove screws 55010 (see 41-E changer instruction manual). Set selector lever in one side position and run through 1 cycle. Although changer is shipped in 1 side position to prevent jam, main cam switch 57155 (see 41-E manual) may shift in transit, resulting in a jam.
4. The record changer must be free-floating and all 4 cushion supports in proper position. If changer is not free-floating, its position should be shifted slightly until there is no tendency to touch against any part of the mounting frame.
5. Level the cabinet with adjustable glides which are contained in a separate bag attached to the inside of shipping case. This is important for proper automatic phonograph operation.
6. Check level of changer mechanism in cabinet.

**FARNSWORTH TELEV. & RADIO CORP. MODELS CAPEHART,
PANAMUSE N SERIES**

7. Determine whether the power-line voltage and frequency agree with the electrical specifications on plate on rear of the instrument.

8. Read carefully operating instructions accompanying the instrument.

9. Place a phonograph record on the turntable. Place "on-off" switch on changer to "on" position. Set all controls; volume, bass, treble, in wide-open position for acoustic feedback test. RCA record No. 49196 is good for this purpose. This test will indicate any excessive noise or rumble. Shifting the changer to a free-floating position while this record is playing should clear up any rumble which may be present.

10. Operate volume, bass, and treble controls to observe proper action.

11. Check for reproduction quality. To do this, use a good record, of quality and type of reproduction with which you are familiar. Check record reproduction at both high and low volume levels.

12. Examine antenna connections. Check reception and calibration of radio tuner on all bands.

13. Observe action of the "Electric Eye" tube and position so that tuning segments are horizontal.

14. Tap tubes in tuner to locate any excessively microphonic tubes.

15. Affix station call letter tabs on the dial, following procedure in operating instructions. The knobs must be removed before the escutcheon can be replaced. The escutcheon is wrapped in the cardboard screwed to the inside of the cabinet near the base. After the escutcheon is attached, replace the knobs.

16. Effect a complete check of the record changer

17. Carefully clean cabinet to remove finger marks. A piece of cheesecloth folded into a pad and moistened with water to which a few drops of vinegar have been added is recommended. The use of furniture polish on Capehart cabinets is not recommended.

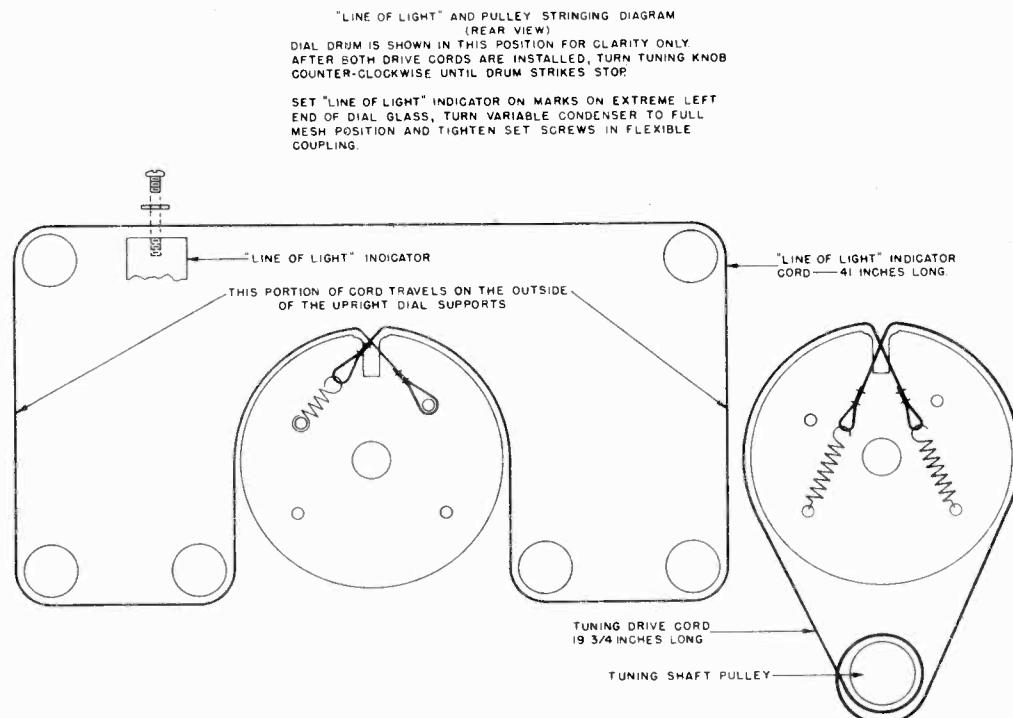

18. Instruct customer on all phases of operation of the machine. Personally place in the customer's hands the operation manual which accompanies the instrument.

DRIVE CORD ASSEMBLIES

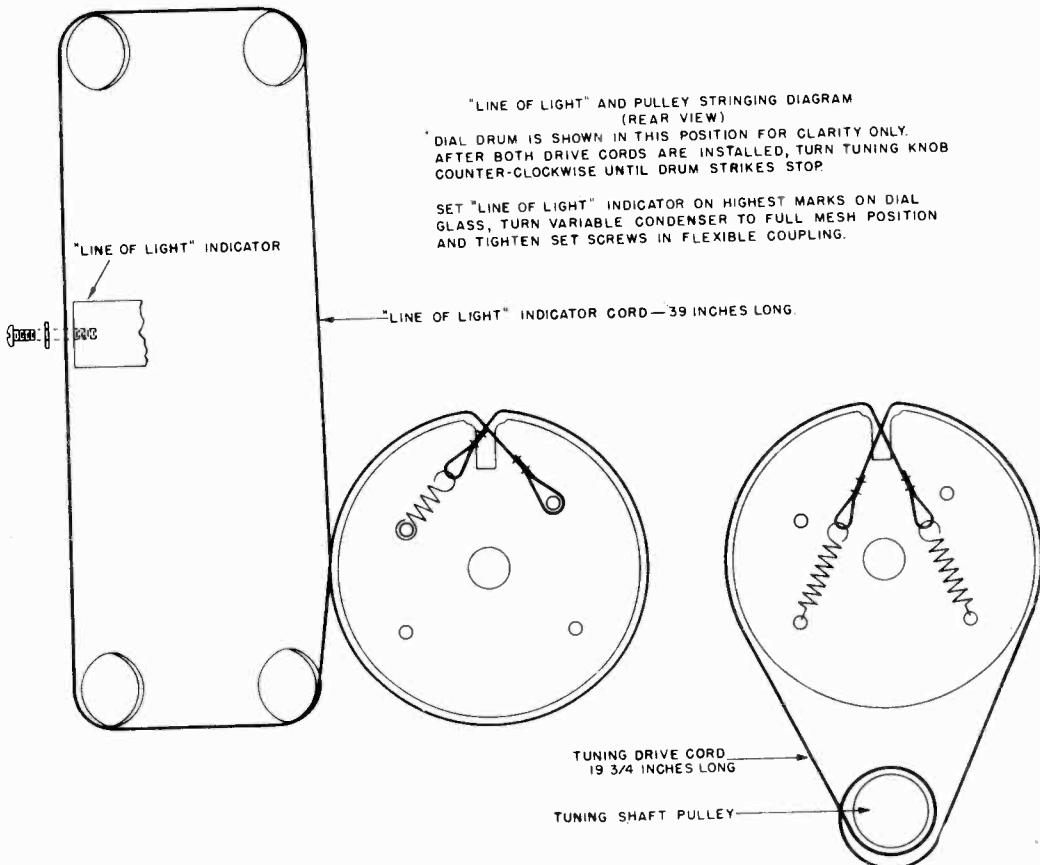

SECTION 9

The dial cord assemblies are 2 in number; the main drive cord which causes rotation of the drum, and a second cord which operates the traveling-

light dial scale indicator. As an aid in stringing these cords, the schematics of both the vertical and horizontal type dials are shown below:

RECEIVER ALIGNMENT

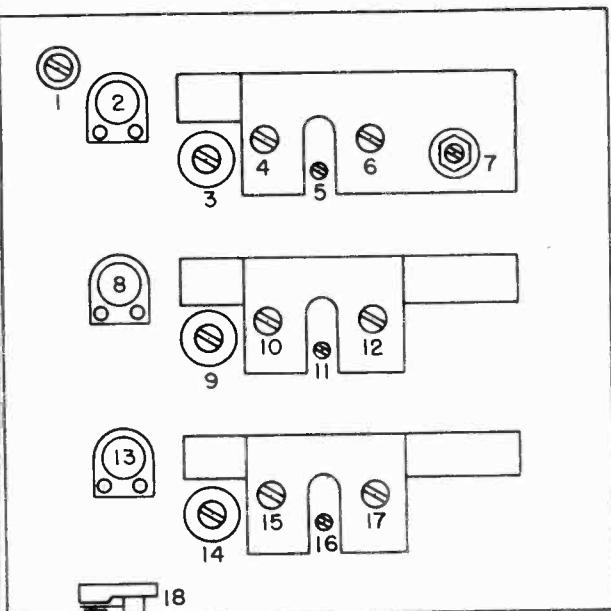

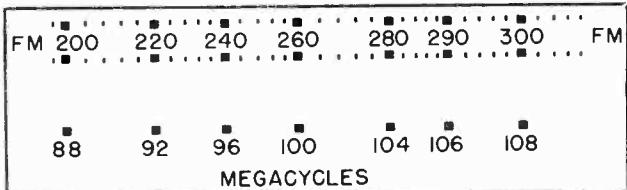

SECTION 10

Herewith are presented two methods of alignment of the Capehart receivers. Those service shops possessing a suitable sweep generator and oscillograph will effect considerable saving of time, as well as assuring more precise alignment, by using the first method, Section 1.00 through Section 7.08. This method is employed in factory alignment.

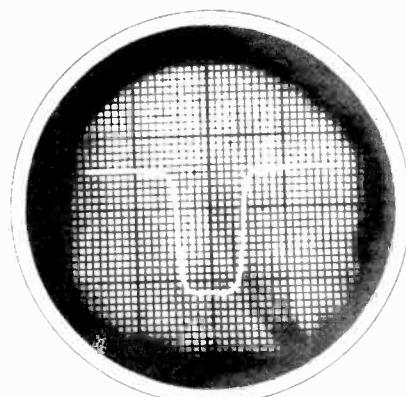

An alternative method, using the amplitude-modulated signal generator, is presented in the second portion of the papers which covers alignment of the FM-IF stages (Section 10.00 through Section 13.00) and of the AM portion of receiver (the chart showing Steps 1-22 which should be followed in sequence).

By following these detailed procedures, the original factory alignment of the receiver may be duplicated.

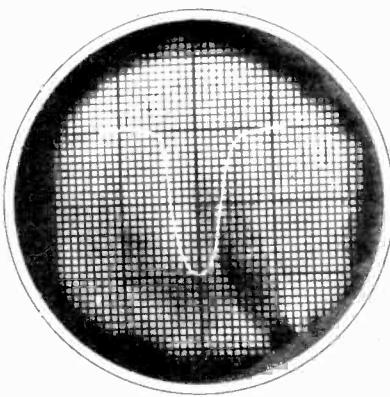

The conversion of FM dial scale readings to frequency may be made from the following analysis: The FM band extends from 88 to 108 mc., each station channel 200 kc. in width. Channel 201, that lowest in frequency, has center frequency at 88.1 mc. Each succeeding channel is successively 200 kc. higher, so channel 202 is centered at 88.3 (200 kc. higher), channel 203 is centered at 88.5 mc., 206 at 89.1 mc., etc.

PANAMUSE N SERIES

ALIGNMENT OF THE RECEIVER, SWEEP GENERATOR METHOD

1.00 GENERAL INSTRUCTIONS

1.01 Adjustments of Dial Pointer

a. Tune receiver to extreme low frequency end of dial and set pointer to index at the last calibration mark.

b. Carefully determine that the gang condenser plates are completely meshed with the pointer in this position.

WARNING: This adjustment is extremely important if subsequent alignment is to provide accurate calibration.

c. With the pointer at the extreme low end of the range, rotate band switch through all positions and note that the pointer line is accurately indexed on all three bands, and that the pointer is illuminated for the proper band in respect to the position of the band switch.

Note: The pointer remains dark when the band switch is in the phonograph position.

d. Tune the dial across the entire range and observe that the pointer line is a single sharply defined line of uniform brilliance. If this is not obtained, it indicates that mechanical adjustment of the spacing of the light box from the dial glass is necessary. Do not proceed with alignment until all mechanical adjustments have been made.

1.02 TUNING EYE BALANCE ADJUSTMENT

Remove last FM IF tube from its socket. Turn band switch to FM position, and adjust tuning eye balance control (located on top of the chassis between the 6H6 discriminator tube and discriminator transformer) for balance of the 2 sections of the eye. No further adjustment of this control is necessary or should be attempted. The IF tube is then replaced. If, after alignment has been completed the tuning eye does not assume this same degree of balance, it is an indication the FM IF alignment is incorrect and should be reworked. This observation must be made with no signal input to receiver. After electrical balance has been obtained, the tuning eye must be rotated in its mounting such that the 2 wedge shaped dark areas will be in horizontal alignment to the chassis.

1.03 SETTING OF RECEIVER CONTROLS

Unless otherwise indicated, the receiver controls shall be set as follows during all alignment operations:

a. Set treble tone control to maximum treble position (pointer up).

b. Set bass tone control to maximum bass position (pointer up).

c. Set volume control to maximum.

1.04 TEST SIGNAL CONDITIONS

All alignment shall be done with only sufficient signal amplitude to provide satisfactory, signal to noise ratio, and acceptable pattern size on oscilloscope or readable output on output meter. *The use of excessively strong signal is almost certain to produce misalignment.*

2.00 Equipment Required

2.01 455 KC IF sweep generator.

2.02 10.7 MC IF sweep generator.

2.03 5" cathode ray oscilloscope.

2.04 RF signal generator, range 400 KC to 18 MC.

2.05 RF signal generator (frequency modulation desirable). Range 88 to 108 MC.

2.06 Output meter.

2.07 Insulated screw driver.

2.08 Voltohmyst.

3.00 FM IF ALIGNMENT

3.01 Equipment required: From Section 2.00 use items numbers 2.02, 2.03, and 2.08.

3.02 Set band switch in FM position and other controls as in Section 1.03.

3.03 Make connection from vertical deflection amplifier of oscilloscope to pin #3 of 6H6 discriminator tube. Make certain that the 4 MFD electrolytic condenser is disconnected from this same circuit. It is necessary that the lead to the oscilloscope be shielded, of low total capacity, and connection to receiver isolated by means of a 1 meg. resistor.

3.04 Connect sweep generator to last FM IF grid (Pin 4) through a .1 MFD coupling capacitor.

3.05 Align discriminator to obtain a picture similar to an over coupled IF transformer.

3.06 Place 10K resistor across primary of discriminator transformer and retouch alignment to obtain symmetrical pattern. It will be noted that the pattern is now single peaked but rather broad. This does NOT constitute a final alignment of discriminator, but is a convenient expedient to assist in the alignment of the IF stages.

3.07 Shift connection of sweep signal generator to the grid of the second FM IF tube (Pin 4).

3.08 Align third FM IF transformer for a symmetrical flat top pattern.

3.09 Shift signal generator to the grid of the first IF tube (Pin 4).

3.10 Align second IF transformer in same manner as described in Section 3.07. NOTE: The width of the nose of the curve is the same as before, but the sides have become steeper.

3.11 Connect the signal generator to the grid of the converter tube grid (Pin 1) in series with 10,000 ohm resistor and a .1 MFD capacitor, or loosely couple by stray capacity of an insulated wire.

3.12 Align first FM IF transformer in the same manner as in Section 3.07. NOTE: The sides of the curve have further steepened, but that the nose of the curve has retained approximately the same width.

3.13 Remove load resistor from primary of discriminator transformer and connect 4 MFD electrolytic capacitor that was previously disconnected.

3.14 Connect oscilloscope to audio output terminal of the discriminator. There are several points where this contact can be made and can be identified as the circuit connected to the terminal of the discriminator transformer to which a shielded lead is connected.

3.15 With sweep signal input to converter grid, (Pin 1) align discriminator transformer for conventional discriminator pattern.

3.16 Connect signal generator to converter tube grid (Pin 1) in series with a 10,000 ohm resistor and a .1 MFD condenser capacitor. A signal input of 4,000 uV at 10.7 MC shall develop 3 volts AVC as measured with a voltomyst.

FARNSWORTH TELEV. & RADIO CORP. MODELS CAPEHART, PANAMUSE N SERIES

4.00 FM RF ALIGNMENT

4.01 Equipment required: From Section 2.00 use items 2.05, 2.06, 2.07, and 2.08.

4.02 Connect RF signal generator in series with 400 ohm carbon or metalized resistor to terminal "D" of RF unit nearest the side of the tuner (extreme left hand terminal viewing rear of chassis).

4.03 Set tuning control for pointer to calibrate at the equivalent of half way between channels 300 and 301.

4.04 Apply 108 MC signal.

4.05 Set converter and antenna trimmers at minimum capacity.

4.06 Adjust oscillator trimmer by tuning from maximum capacity to first signal that is heard, and peak for maximum output.

4.07 Adjust antenna and converter trimmers from maximum output.

4.08 Set tuning controls so dial pointer calibrates at the equivalent of half way between channels 200 and 201.

4.09 Apply 88 MC signal.

4.10 Adjust oscillator slug to maximum output.

4.11 Repeat operations 4.03 to 4.10 inclusive.

NOTE: The degree of adjustment required in the tuning of the oscillator slug will determine the number of times operations 4.03 to 4.10 must be repeated until no further gain in sensitivity is obtained.

4.12 Carefully tune across the entire FM band for the observance of dead or weak spots that may be a function of improper alignment or defective components. This can be determined by carefully noting the degree of receiver noise, that is, high noise generally is accompanied by good sensitivity.

4.13 Signal input of 18 uV should produce approximately 3 volts AVC as measured with a voltohmyst.

4.14 With no signal input to antenna the tuning eye should have the same balanced appearance as it had following operation 1.02. If this is not the case, it usually indicates inaccurate alignment of IF system.

5.00 AM IF ALIGNMENT

5.01 Equipment required: From Section 2.00 use items 2.01, 2.03, and 2.08.

5.02 Set band switch in broadcast position and other controls as in Section 1.03.

5.03 Connect oscilloscope to high potential side of volume control.

5.04 Connect 455 KC sweep generator to the grid of the second AM IF tube through a .1 MFD condenser.

5.05 Align diode transformer for symmetrical conventional IF pattern.

5.06 Connect signal generator to grid of first IF tube.

5.07 Align second IF transformer.

5.08 Connect signal generator to converter grid.

5.09 Align first IF transformer.

NOTE: The resulting overall pattern shall be symmetrical and slightly flat topped.

5.10 Signal input of 2700 uV should produce approximately 3 volts AVC as measured with a voltohmyst.

6.00 BROADCAST BAND RF ALIGNMENT

6.01 Equipment required: From Section 2.00 use items 2.04, 2.06, 2.07, and 2.08.

6.02 Place antenna loop switch in antenna position.

6.03 Connect RF signal generator to either terminal "D" through 200 MF mica capacitor.

6.04 Set dial pointer to 1500 KC.

6.05 With 1500 KC signal align oscillator, converter, and antenna trimmers for maximum output.

6.06 Set dial pointer at 600 KC.

6.07 Align oscillator padder, converter and antenna slugs for maximum output. Do not adjust the coil slug in broadcast oscillator coil.

6.08 Repeat operations 6.04 to 6.07 inclusive until no further increase in sensitivity is obtained.

6.09 Check dial calibration at several frequencies. If calibration is not reasonably accurate it will be necessary to make an adjustment of the inductance slug.

WARNING: After any adjustment of the oscillator inductance slug it will be necessary to repeat operations 6.04 to 6.07 inclusive.

6.10 Signal input of 35 uV at 1000 KC should produce approximately 3 volts AVC as measured with a voltohmyst.

6.11 Switch antenna loop switch to loop position.

6.12 Connect dummy loop to terminal L-1 and L-2, and signal generator to antenna connection of dummy loop.

6.13 Set dial pointer to 1500 KC.

6.14 With 1500 KC signal align the loop trimmer for maximum output.

6.15 Check sensitivity at 600 and 1500 KC.

7.00 SHORT WAVE RF ALIGNMENT

7.01 Equipment required: From Section 2.00 use items 2.04, 2.06, 2.07, and 2.08.

7.02 Set band switch in short wave position and other controls as in Section 1.03.

7.03 Connect RF signal generator to either terminal "D" through a 400 ohm resistor.

7.04 Set dial pointer to 15 MC. Adjust oscillator, converter, and antenna trimmers for maximum output.

WARNING: On the short wave band the oscillator is operating on the low frequency side of the RF signal. Therefore, to avoid error in setting oscillator frequency, first set oscillator trimmer to maximum capacity, then slowly turn trimmer until first signal is heard.

7.05 Set dial pointer to 9.5 MC.

7.06 Adjust oscillator, converter, and antenna slugs for maximum output.

7.07 Repeat Sections 7.04 to 7.06 inclusive, until no further gain in sensitivity is obtained.

7.08 With signal input of 90 microvolts at 15 MC should produce approximately 3 volts AVC as measured with voltohmyst.

Upon completion of all alignment the oscillator padder should be sealed with a touch of glyptal on the adjustment screw and Ambroid or similar cement applied to all coil slugs to prevent their changing adjustment.

MODELS CAPEHART, FARNSWORTH TELEV. & RADIO CORP.

PANAMUSE N SERIES

TABULATION FOR AM ALIGNMENT

10.00-10.04 Same as 1.00-1.04.

11.00 EQUIPMENT REQUIRED

11.01 Voltohmyst.

11.02 R-F signal generator range 450 KC to 108 mc.

11.03 Insulated screw-driver.

12.00 FM IF ALIGNMENT

12.01 Equipment required: From Section 11.00 use items numbers 11.01, 11.02, and 11.03.

12.02 Set bandswitch in FM position and other controls as in section 10.03.

12.03 Connect voltomyst from ground to pin #3 on 6H6 ratio detector.

12.04 Connect signal generator in series with a .1 MFD capacitor between grid and ground of 3rd FM IF tube (Pin 4) and set generator to 10.7.

12.05 Disconnect 4 mfd. condenser (1 lead is sufficient from detector circuit and place 10,000 ohm resistor across primary of the fourth or discriminator transformer. Resistor shall be left connected until operation calling for its removal.

12.06 Tune secondary and primary slugs for maximum voltage.

12.07 Connect generator in series with a .1 mfd. capacitor to grid of 2nd FM IF tube.

12.08 Place a 2200 ohm resistor across secondary of 3rd FM IF transformer.

12.09 Tune primary slug for maximum voltage.

12.10 Remove 2200 ohm resistor from secondary (and place across primary of same transformer).

12.11 Tune secondary slug for maximum output.

12.12 Remove 2200 ohm resistor from primary of 3rd FM IF transformer and place across secondary of 2nd FM IF transformer.

12.13 Connect generator, in series with a .1 mfd. capacitor to grid of 1st FM IF tube.

12.14 Tune primary slug for maximum voltage.

12.15 Remove resistor from 2nd IF transformer secondary and place across primary.

12.16 Tune secondary for maximum voltage.

12.17 Connect generator to grid of FM converter tube through a 10,000 ohm resistor and 1 mfd. condenser in series of loosely couple to the grid by placing the generator lead near the grid lead.

12.18 Remove resistor from 2nd IF transformer primary and place it across secondary of 1st IF transformer.

12.19 Tune primary slug for maximum voltage.

12.20 Remove resistor from secondary and place it across the primary.

12.21 Tune secondary for maximum voltage.

12.22 Move voltmeter to audio output lead on 4th FM IF transformer. This is a shielded lead.

12.23 Remove the 10,000 ohm resistor from the discriminator primary that was installed in item 12.05. Tune secondary of 4th FM IF transformer for zero voltage. Slight returning of the primary may be necessary after the secondary is tuned.

12.24 Tuning of the primary is done by slightly detuning signal generator to obtain a readable out-

put then tuning slug for maximum. This operation and that of 12.23 must be repeated several times to obtain final accurate alignment.

12.25 The FM IF system is now aligned. Detuning the signal generator equal amounts each side of 10.7 mc should produce equal deflections of opposite polarity on the voltmeter. If the deflections are not equal (+10% or less) the alignment is not correct and the discriminator requires re-alignment.

13.00 FM RF ALIGNMENT

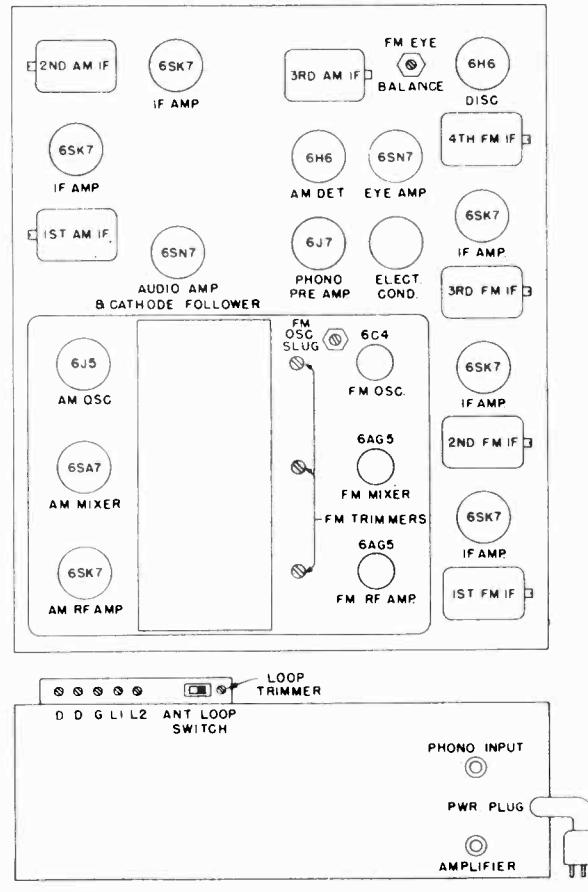

Follows exactly that given in sections 4.01 to 4.14.

14.00 ALIGNMENT OF THE A-M BANDS

Equipment required: Same as section 11.

CAUTION: Care must be taken when aligning the short wave band, for the adjustment of the shunt trimmer affects the adjustment of the oscillator coil slug.

At the high frequency end of the band it is possible to peak the oscillator trimmer, and to peak the slug at the low frequency end at the image; so in the alignment instructions we have indicated the fundamental frequency and the correct oscillator setting for the image so that by resetting the signal generator it is possible to see if the alignment is correctly made. In each case the image is found at a frequency 910 Kc. higher than the fundamental.

MAINTENANCE OF THE TUNER

SECTION 11

This section of the Maintenance Manual is purposed, in part, to acquaint the service man with the chronological status of the tuner. The automobile industry effects certain minor modifications to their product from time to time. In like manner, circuit developments, the result of a continuous program of searching for means of improving the instrument, lead to the incorporation of modifications as enumerated below.

In addition, herein are presented the solutions to maintenance problems which the service man may encounter, which solutions will assist him in the efficient servicing of the N-series tuner. The material is listed by subject headings which will quickly permit access to the information:

1. Capehart N-series tuner code markings.
2. High hum level.
3. Tone reproduction
 - a. Increasing the high frequency response.
 - b. Increasing the bass response.
 - c. Increasing the range of the treble control.
 - d. Tone reproduction—model 413N and NC
3. Tone reproduction—general.
 - a. Increasing the high frequency response.
 - b. Increasing the bass response.
 - c. Increasing the range of the treble control.
 - d. Tone reproduction—model 413N and NC
- instruments.
4. Dial drive adjustments.
5. Control knobs; eccentric, loose, how to remove.
6. Dial-glass plate.
7. Microphonics.

1. CAPEHART N SERIES TUNER CODE MARKINGS

Certain "N" series receivers are coded by "circle markings" to indicate electrical circuit modifications. These markings are located on top of the first FM IF transformer (BLACK PAINTED CAN ON REAR OF CHASSIS TO THE EXTREME RIGHT WHEN VIEWING REAR OF CHASSIS) and are in the form of red circles approximately one-half inch in diameter enclosing the initials F.T.R. and tester's number.

Following is a listing of the significance of these markings, whereby you may identify any chassis:

A. NO CODE MARKS

These tuners do not incorporate any of the modifications which are below-listed.

B. ONE CIRCLE

Indicates the change to a modified discriminator transformer in production which increases sensitivity and noise reduction.

(a) De-Emphasis Condenser

For tuners coming under classifications (A) and (B) above, we recommend the addition of a .001 mfd. de-emphasis condenser. In FM transmission, the high modulation frequencies are pre-emphasized (their

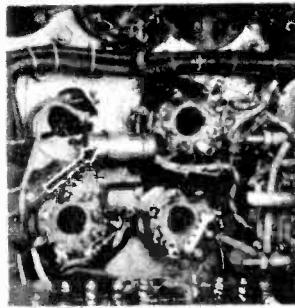

amplitude made greater). Heretofore, non-uniformity between stations caused some to evidence, in the receiver, apparent distortion—too much high-frequency response. Now, with greater uniformity in pre-emphasis, we can arrive at a more suitable overall amount of de-emphasis.

The de-emphasis condenser should be connected from the band switch side of the 47,000 ohm resistor which connects from the output of the discriminator to the auxiliary band switch, being mounted on the front wafer of the auxiliary band switch. Connection is made from the above-mentioned point to ground.

(b) Tuning Eye Time Constant

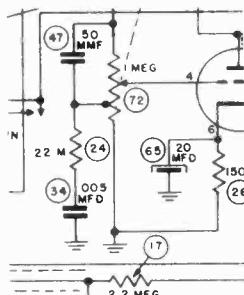

The action of the "eye" may be slowed-down by a longer time constant in its control circuit. This is accomplished by substituting a .1 mfd. condenser for the .01 mfd. unit connecting from pin #4 of the eye amplifier to ground. A 200 volt condenser is satisfactory.

(a) and (b) are not essential unless the customer desires a change but if the tuner is being serviced, it is suggested that these easily-performed modifications be made.

C. TWO OR THREE CIRCLES

(a) These chassis may have resistor-capacitor values, from volume control tap to ground, of 220,000 ohms and .003 mfd., in which case the bass-boosting effects (at low volume levels) of the tap are not great. A .005 condenser and 22,000 ohm resistor will increase the bass-boost effects.

(b) These circles also indicate a change in the connection of the 50 mfd. condenser associated with the single volume control circuit. Connection is changed from (1) between top of control and moving arm to (2) between top of control and fixed tap. This increases the bass response of the tuner at low volume levels.

D. FOUR CIRCLES—Tuners with 4 circles contain the above modifications.

E. ONE SQUARE—This signifies the tuner which incorporates a dual volume control as shown on the schematic, page 12. It also embodies all of the modifications listed in this portion of the manual.

2. HIGH HUM LEVEL

a. With external jumper, connect the 2 chassis together to check the ground connection in the audio cable.

**MODELS CAPEHART, FARNSWORTH TELEV. & RADIO CORP.
PANAMUSE N SERIES**

b. Many tubes recently produced have heaters contaminated with the Barium-Strongium oxide emissive material, causing emission from heater to cathode if the cathode is positive with respect to the heater. This is a condition over which we have no control and we may only

(a) Substitute 6J5 or/and 6L6 tubes until those which have no such contamination are found or (b) Place the heaters at a positive potential with respect to cathode by:

1. Remove 6J5 (also 6L6 in N-2) heaters from ground. Also remove power transformer heater winding from ground.

2. Re-wire that side of the heater supply, using pin #6 (which is empty) as tie-down points, leaving both sides of the heater off ground.

3. Connect a 220,000 ohm and a 22,000 ohm resistor, in series, from +B to ground, the 22,000 ohm unit being placed at the ground end of the combination.

4. Connect the junction of the resistors to whichever side of the heaters results in the least hum.

This divider network places an approximate positive 30 volt potential upon the heaters.

All tuners in current production incorporate this feature.

3. TONE REPRODUCTION

The tonal reproduction of radio-combination instruments is occasionally commented upon by customers to be not in agreement with their personal preferences.

The human ear and the appreciation of musical rendition is a variable requiring some leeway in tonal reproduction—thus tone-control adjustments, "treble" and "bass."

Should the customer desire a modification of the characteristics of his instrument, certain circuit re-arrangements may be made to effect the desired change. It is not recommended that such changes be done to sets whose tonal characteristics fulfill the individual's personal preferences.

Below are listed means of effecting a change in the receiver to accomplish increased high or low-frequency response and greater control-range of the treble control.

A. Increasing the high-frequency response.

If the instrument appears to lack high-frequency response

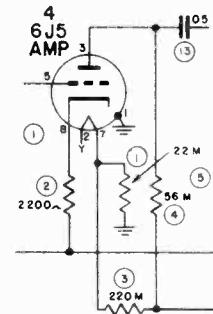

(a) Check the value of the capacitor in the pick up equalizer circuit. This component is mounted in the small shield can directly under the coupling shaft to the variable condenser. It should have a value of .0001 mfd. shunted with a 1.5 megohm resistor.

B. Increasing the Bass Response

(a) The resistor-capacitor combinations of part 1C should be checked.

C. Increasing Range of Treble Control

If comments are received regarding insufficient maximum treble control, the effect of this control may be increased as follows:

(a) Remove the shielded lead from terminal #5, also remove bus wire jumper between terminals 1 and 5 of the 6SN7GT first audio tube.

(b) Connect the shielded lead to pin #1 and install a 22,000 ohm half-watt resistor between pins 1 and 5. This makes each step of the treble control more pronounced and aids in minimizing record surface noise.

NOTE: Tuners "code marked" 3 or 4 circles incorporate this modification.

D. Tone Reproduction Model -413N and NC Instruments

The changes listed below are for purposes of rendering the reproduction more in keeping with the average ear and the personal preference of the listener. They are over-and-above the previous modifications and should be applied, if the 413N instrument is to be modified, after the pertinent previous changes have been made.

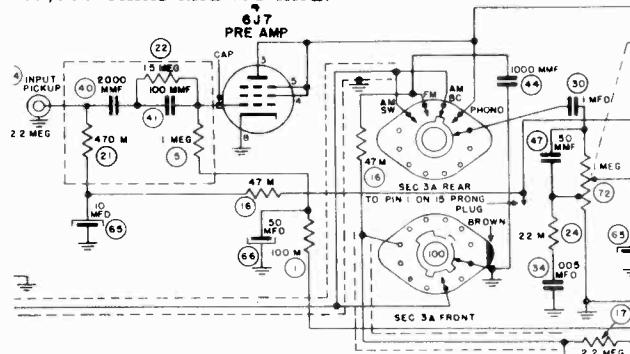

This applies to chassis with a 2, 3 or 4 code mark now in the field.

1. Change the grid resistor of the 6J7 phono preamp tube from 1 megohm to 470,000 ohms.

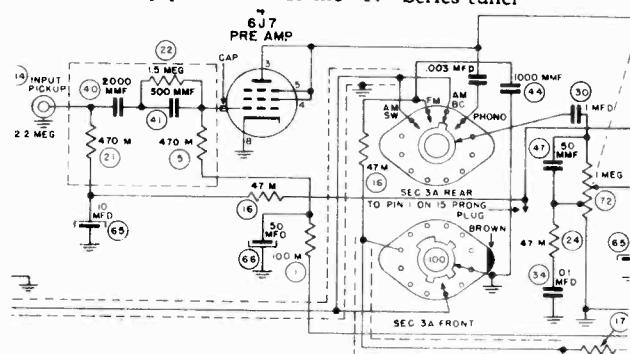

2. Change the condenser in series with the 6J7 preamp tube grid from 100 mfd. to 500 mfd. This is the condenser which has a 1.5 megohm resistor in shunt with it. This resistor should remain in the circuit.

3. Insert a .003 mfd. mica condenser in the connection between the plate of the 6J7 preamp tube and the band switch.

4. Change the series resistor-condenser connected from volume control tap to ground, to 47,000 ohms and .01 mfd.

Early production of the "N" Series tuner

Modifications of Section D, above (413N and NC instruments only)

**FARNSWORTH TELEV. & RADIO CORP. MODELS CAPEHART,
PANAMUSE N SERIES**

We pass on to you below the solution to several service problems which have been experienced in the field, anticipating that they may effect a saving of time and more efficient servicing on your part.

4. "N" TUNER—DIAL DRIVE

ADJUSTMENTS

If dial slippage is experienced:

A. Clutch slipping. Tighten the drive clutch as tight as possible.

B. "Sticking" light boxes. The traveling light box may be sticking, causing dial slippage. This may be due to (a) lubricant on rods, (b) bent rods, (c) rough rods, (d) misalignment of rods.

(a) *The rods must be free of all lubricants.*

Lubrication, momentarily helpful, causes gum to form at the light-box mounting, resulting in "sticking." Clean well with carbon tetrachloride.

(b) Bent rods must be accurately straightened or replaced.

(c) Rough portions of the rod surface should be cleaned with crocus cloth until perfectly smooth.

C. Old type of endless belt. If this belt has stretched, the newer-type may be installed by:

(a) Remove the center mounting bolt for the center resistor strip toward the FM IF section of the receiver.

(b) Remove band switch rod. Remove the program switch and lay back out of the way. (No wires need be disconnected.)

(c) Remove all parts of the idler pulley assembly and discard.

(d) Replace the drive pulley and split-gear assembly with the later type which is similar to the old type but has wider belt groove. Be sure that there is some tension on the split gear springs to avoid backlash.

(e) Remove the upper dial bracket to allow free access to the drive down.

(f) With a small rat tail file, file down the square shoulder on the drive drum at the cable cross over point. This is done to allow more space for the 2 ends of the drive cable to cross without binding. Also, dress down the ends of the drive cable channels.

(g) Install new drive cable, winding 1½ turns about the drive pulley.

(h) In reinstalling program switch, be sure that it is properly indexed with band switch.

5. DIAL GLASS PLATE

Paint scratched. This is due to the light-box assembly contacting the painted surface. Adjust the horizontal positioning of the light box for optical focus of the projected line of light, so that (1) focus is maintained throughout the entire path of travel, (2) front of light-box assembly does not at any point touch the scale. The clamps which

hold the glass rod in place may be clipped back if necessary.

Touch-up paint may be obtained at automobile service stations.

**6. CONTROL KNOBS—ECCENTRIC—
LOOSE—HOW TO REMOVE**

A. *Knobs eccentric (wobbly motion) or loose.*

This is caused by pinching together the 2 halves of the split-shaft end. One half-section becomes bent toward the axis of the shaft to a greater degree than does the other. Re-form the split portions of the shaft so that they are symmetrical with respect to the axis of the shaft.

B. To Remove Control Knobs

Loop a heavy cord behind the knob, bringing out the two ends at opposite sides of the knob. Pull both ends firmly. If the cord (both ends) is brought out on one side only, there will be a tendency to cause the difficulty of 6A, above.

7. MICROPHONICS AND FEEDBACK

A. Microphonic tubes.

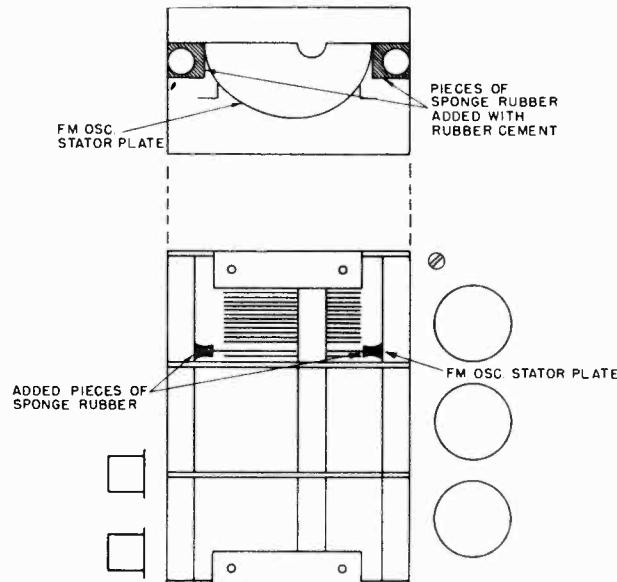

B. Check the variable condenser stator plates to ascertain whether they are loose. If so, apply a collodial cement to the clamp which holds the stator plates to the insulating material.

C. "Twin lead" to antenna binding posts may be stapled to cabinet in taunt condition, whereby feedback is introduced mechanically. Re-staple the twin lead, leaving somewhat free and loose.

D. On FM microphonics and howl may be caused by the lead from stator plate to sub-chassis assembly being taunt. Re-solder with less tension in the flat ribbon lead.

NOTE: Oscillator trimmer may have to be re-adjusted.

E. If howl on the FM position persists, the following may alleviate the condition: Sponge rubber bits added as shown in sketch. Rubbers must be trimmed so that they will not touch rotor plates when the condenser gang is fully-meshed.

REMOTE SPEAKER INSTALLATIONS

SECTION 12

No provision has been made, in the design of the instrument, for the use of one or more extension speakers.

In the event that a customer desires a remote-speaker installation, we do not recommend that another speaker be connected either in series or in parallel with the cabinet speaker unit. Such an installation may be had by the use of an added amplifier unit which may be connected, in parallel with the cabinet amplifier, across the output of the tuner.

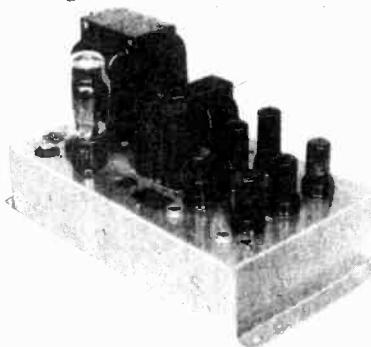

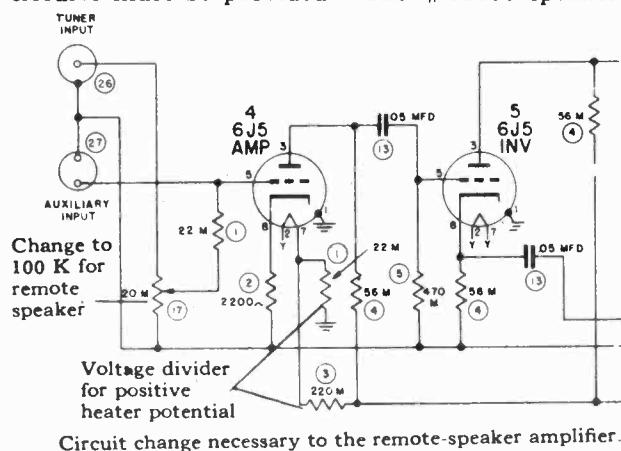

The added amplifier must have its original gain control, a 20,000 ohm unit, replaced by a control of 100,000 ohms. Connection may then be made, through a shielded lead of the low-capacity type, into the extra input jack on the cabinet amplifier chassis. Should it be so desired, the 100,000 ohm auxiliary amplifier gain control may be remotely-connected, for ready accessibility, to its amplifier circuit by individually-shielded leads of the low-capacity type. No shielding is necessary over the wires which connect amplifier to speaker.

If the remotely-located speaker installation is to display characteristics identical to those of the cabinet speaker-amplifier, the remote components must be identical to those of the cabinet; an N-1 amplifier and #81143 speaker for 400N-series instruments, an N-2 amplifier and #81152 speaker for 100N-series instruments. Proper speaker enclosures must be provided. The #81166 speaker

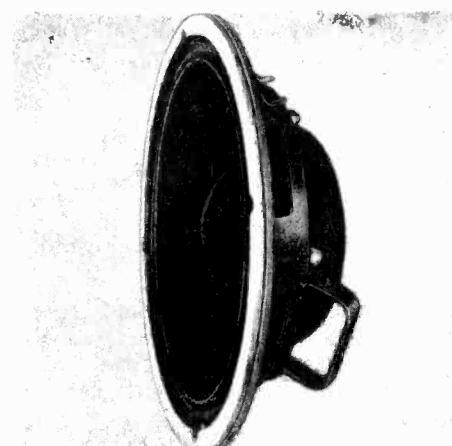

housing should be constructed of at least 1-inch plywood, wholly enclosed, lined with an acoustic absorbent such as hair-felt. Its volume is not less than $2\frac{1}{2}$, nor more than 4 cubic feet.

Should slightly lesser fidelity be permissible in the remote speaker at reduced cost, an N-3 amplifier may be employed as driver unit for the remote speaker. This amplifier provides an output power of 12 watts in an impedance of 8 ohms for driving the #81152 or #81149 speaker.

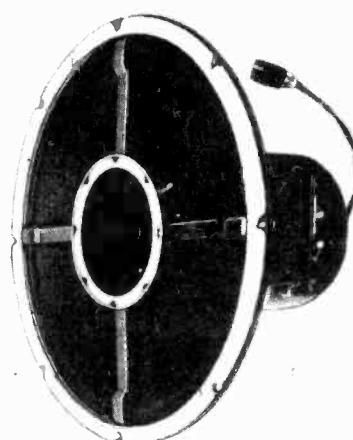

Enclosure for the 12" and 15" speakers, #81149 and 81152 respectively is after the usual fashion for cone-type speakers—it is not to be fully enclosed as is the #81143 unit.

N3 amplifier giving 12 watts power output in 8 ohms.

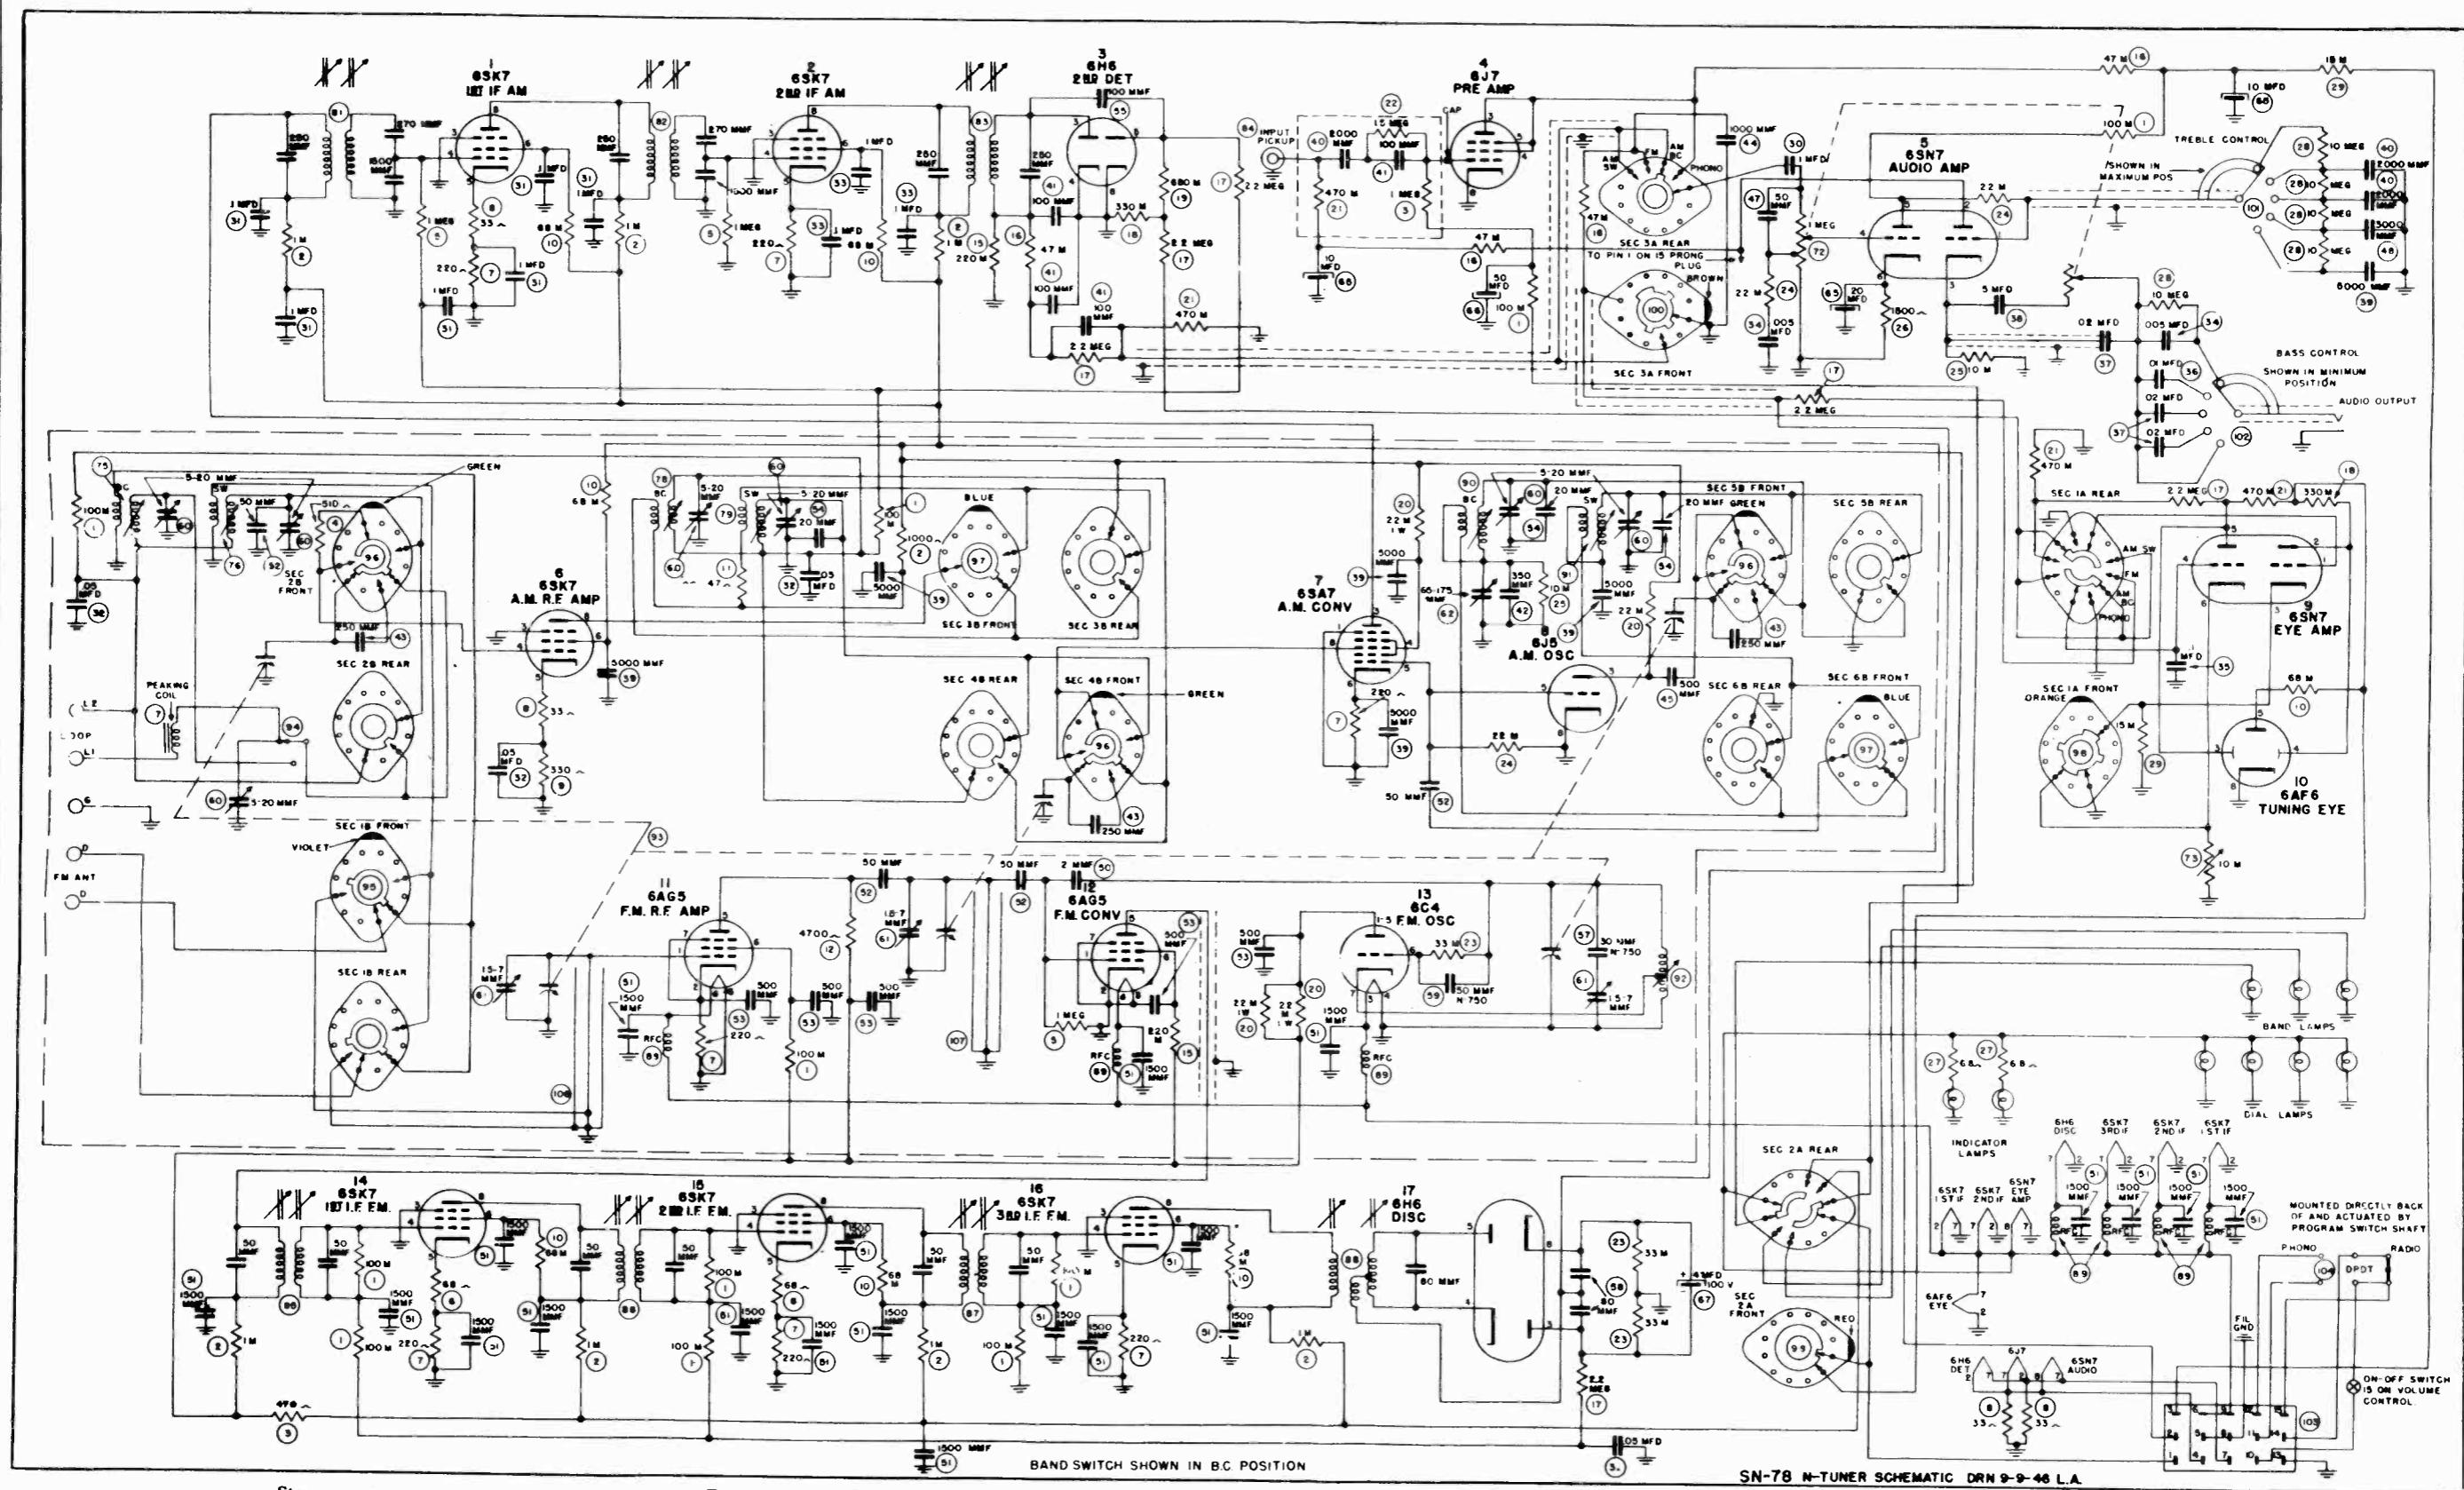

No. 81166 speaker used in 400N model instruments, to be used with the N1 amplifiers. 4 ohms impedance.

No. 81152 (15"), No. 81149 (12") speakers for use with N2 or N3 amplifiers. 8 ohms impedance.

PANAMUSE "N" SERIES CABINET PARTS LIST AND CORRECTION SHEET
26N2

Delete the following parts:

- 13219 Basic glides
56538 Hinge (Soss type)
37376 Lid lift and stay arm mechanism R.H.
37374 Lid lift and stay arm mechanism L.H.

Change part number 67485 Hinge concealed type, etc., to part number 37485 Hinge concealed type, etc.

Add the following parts:

- H-255-1 Cabinet and packing (Bisque).
H-255-2 Cabinet and packing (Cordovan).
67459 Bisque phono lid } Order in matched sets only
67460 Bisque radio lid } sets only
67501 Bisque R.H. speaker door } Order in matched sets only
67502 Bisque L.H. speaker door } sets only
67553 Cordovan phono lid } Order in matched sets only
67554 Cordovan radio lid } sets only
67499 Cord. R.H. speaker door } Order in matched sets only
67500 Cord. L.H. speaker door } sets only
37479 Cabinet glides $\frac{3}{4}$ " nickel plated (4 req.)
37438 Stay arm 13 $\frac{3}{4}$ " phono compartment
13188 Lid lift mechanism radio side.....
13189 Lid lift mechanism phono side.....

25N2

Add:

- 37479 Cabinet glides $\frac{3}{4}$ " nickel plated (4 req.)
37475 Door catch, bullet type (3 req.)

CLARIFICATION OF TUNER PARTS LIST

Part number 07456 Dial drive cord is the pointer drive cord.

Part number 07629 Drive cord assy. is the variable condenser drive cord assy.

Part number 07481 Dial drive cord should be deleted from the Panamuse tuner parts list as it is the Pointer drive cord for the vertical dial 400 series tuner.

Part number 13733 Dial light box assy. should be deleted as this is used only on the vertical dial 400 series tuner.

Delete the following parts:

- H-255-1 Cabinet and packing (Bisque)
H-255-2 Cabinet and packing (Cordovan)
37374 Stay arm and lid lift mechanism L.H.

Add the following:

- 13189 Lid lift mechanism phono compartment
37438 Stay arm 13 $\frac{3}{4}$ " phono compartment
37479 Cabinet glides $\frac{3}{4}$ " nickel plated (4 req.)

The radio door and speaker doors are grain matched to the stationary front panels of the cabinet and are therefore not supplied separately.

19N3

Delete:

- 37497 Cabinet glides $\frac{3}{4}$ " nickel plated (4 req.)

Add:

- 37479 Cabinet glides $\frac{3}{4}$ " nickel plated (4 req.)

All parts on the "N3 Panamuse cabinet parts list—miscellaneous" are common to the N2 Panamuse cabinet except part number 81149 speaker for N3 series Panamuse.

NOTE: 81149 consists of 12" bass speaker and 6" treble speaker assembly for N3 Panamuse.

Add to this list:

- 81150 12" bass speaker only for N3 Panamuse.....
81151 6" treble speaker only for N2 and N3 Panamuse.....
81152 Bass and treble speaker assembly for N2 Panamuse.....
81182 15" bass speaker only for N2 Panamuse.....

Part number 13734 preamplifier phono input assy., should be deleted as it is used only on 400 series tuners.

Part number 31331 Dial Scale should be deleted as this is the dial scale for the vertical dial 400 series only tuner.

Part number 55119 Guide rod should be deleted as it is used only on vertical Dial 400 series tuner.

Part number 55228 Adjustable guide bar should be deleted as it is used only on vertical dial 400 series tuner.

117 VOL 60 CYCLE A.C.
POWER SUPPLY USEDHEATER VOLTAGES MEASURED ACROSS
SOCKET TERMINALS. ALL OTHER VOLTAGES
MEASURED BETWEEN SOCKET TERMINALS AND B—LINE.

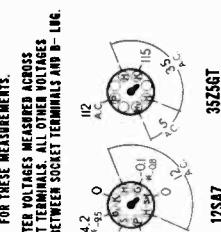

REAR OF CHASSIS

ALIGNMENT PROCEDURE

1. Remove chassis and loop antenna (on cabinet back) from cabinet—allow loop to remain attached to chassis.
2. With the gang condenser fully meshed, dial pointer should be in the position indicated by the last division below 55 on the dial. If it is incorrectly, release pointer clip on dial cord and reposition pointer.
3. Couple the signal generator to the receiver by connecting its output to several turns of wire formed in a circular shape so that it may be placed adjacent and parallel to the receiver loop antenna.
4. Connect an output meter across the speaker voice coil or from the plate of the 35L6GT tube to B—through a 0.1 Mfd. condenser.
5. Set volume control at maximum volume position and use a weak signal from the signal generator.

DUMMY ANT. IN SERIES WITH SIGNAL GENERATOR	SIGNAL GENERATOR CONNECTION	SIGNAL GENERATOR FREQUENCY	RECEIVER DIAL SETTING	TRIMMER OR SLUG NUMBER	TRIMMER DESCRIPTION	TYPE OF ADJUSTMENT
None	Connect directly to coupling turn as instructed in Step 3 above.	455 KC	Any point where it does not affect the signal.	1-2	2nd I.F.	Adjust for maximum output. Then repeat adjustment.
None	Connect directly to coupling turn as instructed in Step 3 above.	1400 KC	1400 KC	3-4	1st I.F.	
None	Connect directly to coupling turn as instructed in Step 3 above.	1400 KC	Tune to 1400 KC generator signal	5	Broadcast Oscillator	Adjust for maximum output.
				6	Broadcast Antenna	Adjust for maximum output.

DIAL AND POINTER
DRIVE CORD
ARRANGEMENT

To string dial cord, turn the main drive drum to maximum counter-clockwise position and use following parts:
 114935 Clip on end of cord
 117057 Cord (4 feet)
 119087 Ring for dial cord
 161384 Tension Spring

TRIMMER LOCATIONS

THE FIRESTONE TIRE & RUBBER CO. MODEL 4-A-10 LATE

STAGE GAIN MEASUREMENT PROCEDURE

REQUIRED INSTRUMENTS: The amount of amplification or "gain" of each of the stages of this receiver may be measured with an A.C. Vacuum Tube Voltmeter or a "channel" type instrument containing a tuned and calibrated amplifier.

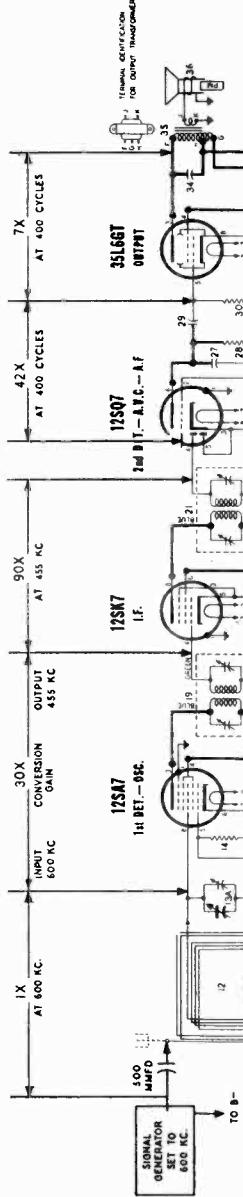

PROCEDURE: It is exceedingly important to adhere to the procedure outlined below since the accuracy of these measurements will be affected to a considerable extent by the failure to establish proper operating conditions.

1. Be sure that R.F. and I.F. stages are carefully and accurately aligned by utilizing the alignment procedure given above.

2. Connect Signal Generator as shown below.

3. The values of stage gain which are given here were measured with a fixed bias of 3 volts on the control grids of all R.F. and I.F. tubes which are connected to the A.V.C. circuit. Therefore, these values are not intended to indicate the full capability of a stage but they will serve as a convenient basis for determining proper operation. In order to duplicate the fixed bias voltage, connect the negative terminal of a 3 volt battery to A.V.C. at terminal "C" of the oscillator coil and connect the positive battery lead to B- in receiver chassis.

4. Set Signal Generator for operation at 600 Kc with 400 cycle modulation and carefully tune radio receiver to this signal by using an output meter to indicate peak output. If a local station interferes, set generator to a nearby frequency and re-tune the receiver.
5. R.F. and I.F. circuits are slightly de-tuned when contact is made with an instrument probe which is indicated by a change in the output meter reading, may seriously affect the gain measurement. Therefore, it is important to adjust the associated circuit trimmer for a maximum output meter reading and to set the input signal level to a convenient reference point on the gain measuring instrument while the probe is making contact. After removing the probe it is again necessary to adjust the trimmer so as to obtain the same output meter reading and thereby assure that the signal voltage at the specified point has not changed as a result of circuit de-tuning.
6. When using a "channel" type instrument carefully tune it for maximum output at desired frequency before making measurements.

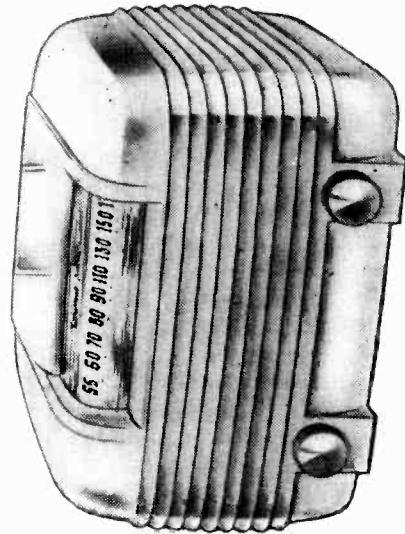

DIFFERENCES in tube characteristics, tolerance of parts, adjustment of tuned circuits and variations in line voltage will influence stage gain. These factors should be given due attention in event the gain of a stage varies extensively from the values shown above.

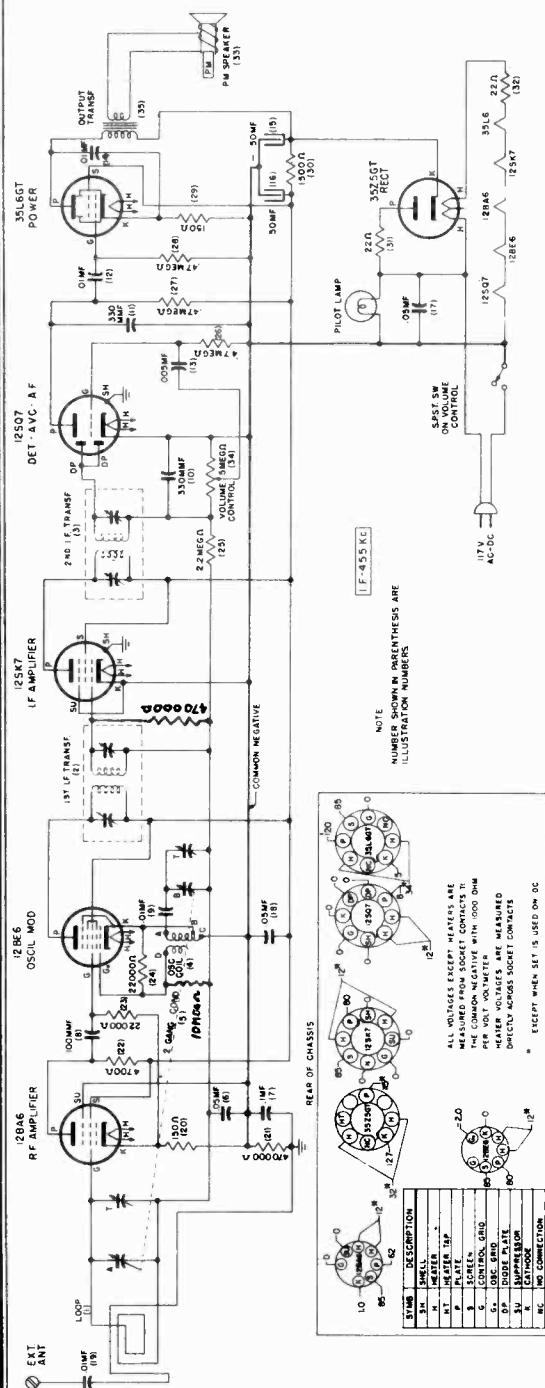

SPECIFICATIONS

CABINET DIMENSIONS	10-5/8" x 7-1/16" x 6-21/32"
WEIGHT	6 pounds 8 ounces
POWER SUPPLY	105 to 125 volts AC-DC
FREQUENCY RANGE	540 to 1600 KC.
I. F. FREQUENCY	455 KC.
SPEAKER	4 inch P-M Dynamic
VOICE COIL IMPEDANCE	3.2 ohms
POWER OUTPUT	Undistorted — 0.8 watts Maximum — 1.2 watts

TUBE COMPLEMENT

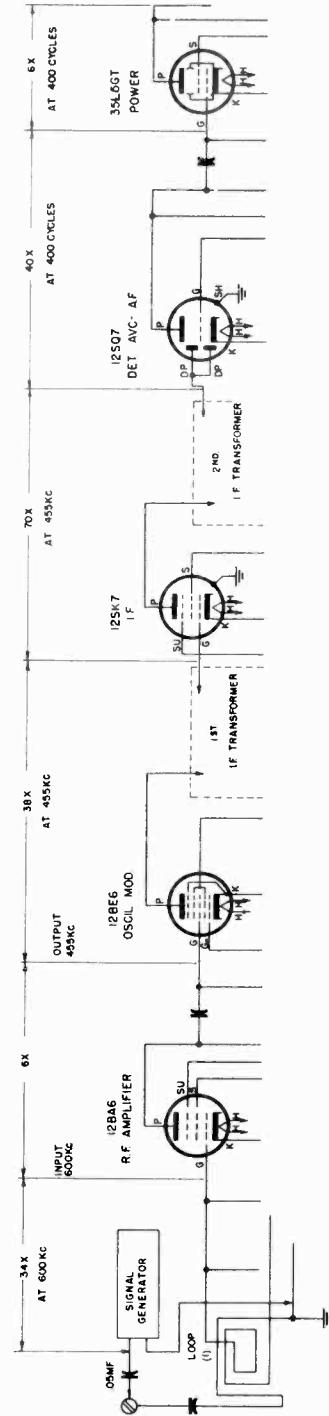

1st Det. — Osc.	12SA7
I. F. Amplifier	12SK7
2nd Det. — A.V.C. — 1st A.F.	12SQ7
Power output	35L6GT
Rectifier	35Z5GT

Be sure R-F and I-F stages are accurately aligned before measuring gain. R-F gains can be measured with a "channel" type instrument containing a tuned and calibrated R-F amplifier. A vacuum tube voltmeter may be used for audio gain measurements. Observe following precautions:

1. For all gain measurements connect signal generator as shown. Use 600 KC signal with 400 cycle modulation (use nearby frequency if local station interferes)
2. Be sure radio is carefully tuned to generator signal (use weak signal for sharp tuning).
3. When using a "channel" type instrument carefully tune it for maximum output at desired frequency before making measurements.

Differences in tube characteristics, tolerance of parts, adjustment of tuned circuits, and variations of line voltage will influence stage gain. Accuracy of measurements is dependent upon careful tuning of receiver to generator signal and experience in using your test equipment. These factors may create considerable variation in gain measurements.

ALIGNMENT PROCEDURE

For alignment procedure read tabulations from left to right, and make the adjustment marked (1) first, (2) next, (3) third.

Before starting alignment:

- (a) Check tuning dial adjustment by tuning gang condenser until plates touch maximum capacity stop (completely in mesh) at which point the dial needle must be exactly $\frac{13}{16}$ " from edge of dial plate. If dial needle does not have this position, move to correct one.
- (b) Use an accurately calibrated test oscillator with some type of output measuring device.

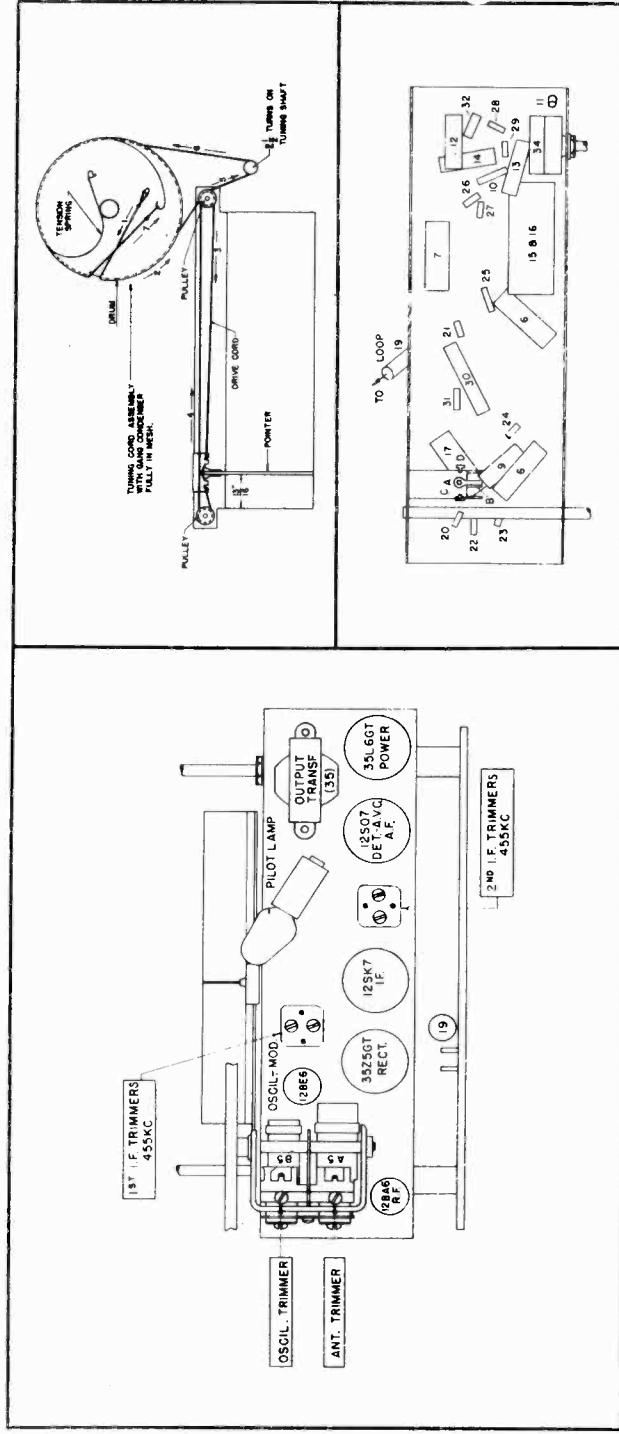

TEST OSCILLATOR			
Step#	Set receiver dial to:	Adjust test oscillator frequency to:	Use dummy antenna in series with output of test oscillator consisting of:
1	Any point where no interneing signal is received.	455 K. C.	.02 MFD condenser
2	Minimum Capacity	Exactly 1620 K. C.	.00025 MFD condenser
3	Approx. 1400 K. C.	Approx. 1400 K. C.	.00025 MFD condenser

Refer to parts layout diagram for location of trimmers mentioned below:

Adjust each of the second I. F. transformer trimmers for maximum output--then adjust each of the first I. F. trimmers for maximum output.

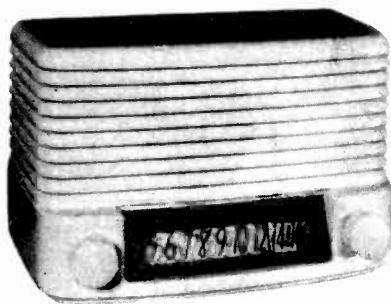

Adjust 1620 K. C. oscillator trimmer for maximum output.

While rocking gang condenser, adjust 1400 K. C. antenna trimmer for maximum output.

MODEL 4-A-11

THE FIRESTONE TIRE & RUBBER CO.

POWER SUPPLY 105 to 125 Volt AC-DC
 TUNING RANGE 540 to 1600 KC
 INTERMEDIATE FREQ. 455 KC
 LOUDSPEAKER 4 Inch P.M.
 VOICE COIL IMPEDANCE 3.2 Ohm at 400 Cycles

TUBE COMPLEMENT
 12BA6 R-F Amplifier
 12BE6 Oscillator Modulator
 12SK7 IF, 12SQ7 Det. AVC.,
 35L6GT Power Output
 35Z5GT Rectifier

POWER OUTPUT Undistorted - 0.8 Watts
 Maximum -- 1.25 Watts

ALIGNMENT PROCEDURE

The chassis and loop should remain in their normal position in the cabinet when making loop adjustment. With the gang condenser fully meshed, the dial pointer should be in the position indicated by the last division below 55 on the dial. If it is set incorrectly, slide the pointer along the dial cord to correct position.

Connect an output meter across the speaker voice coil. Connect the ground side of signal generator to B-. Set the volume control at maximum volume position and use a weak signal from the signal generator.

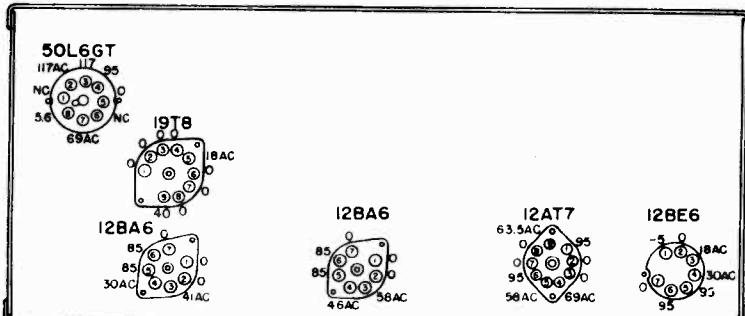

CAUTION: The chassis of this receiver is connected directly to one side of the line. Use an isolation transformer between the 117-volt AC line and AC input to the radio to avoid shock.

Step No.	Band Switch Position	SIGNAL GENERATOR		Connect High Side of Signal Generator to	Radio Dial Setting	Trimmer Letter	Trimmer Description	Type of Adjustment
		Frequency	Type of Modulation					
1	AM	455 kc	30% AM	0.1 mfd. Condenser	12BE6 Grid Pin No. 7	N - O L - M	2nd IF 1st IF	Adjust for maximum output, then repeat adjustment.
2	AM	1620 kc	30% AM	0.1 mfd. Condenser	12BE6 Grid Pin No. 7	D	Oscillator	Adjust for maximum output.
3	AM	1400 kc	30% AM	RMA Loop	Tuned to 1400 kc generator signal.	C	Loop Antenna	Adjust for maximum output.
4	FM	10.7 mc	CW	0.1 mfd. Condenser	12BA6 Driver Grid Pin No. 1	J	Ratio Detector Primary	Adjust for maximum AVC between Point X on wiring diagram and chassis, using Electronic Voltmeter. (See Note 1.)
5	FM	10.7 mc	CW	0.1 mfd. Condenser	12BA6 Driver Grid Pin No. 1	K	Ratio Detector Secondary	See Note 1. Adjust for zero position (using Electronic Voltmeter) from point "Y" on the wiring diagram to the top of the volume control.
6	FM	10.7 mc	CW	0.1 mfd.	12AT7 Grid Pin No. 7	G - H E - F	2nd IF 1st IF	Adjust for maximum AVC. (See Note 1.)
7	FM	108.5 mc	30% FM	300 ohm Carbon resistor	Antenna Terminal J with jumper disconnected.	B	FM Oscillator	Adjust for maximum output. (See Note 2.)
8	FM	87.5 mc	30% FM	300 ohm Carbon resistor	Antenna Terminal J with jumper disconnected.	L ₂	FM Oscillator	Adjust for maximum output. (See Note 2.)
9	FM	108 mc	30% FM	300 ohm Carbon resistor	Antenna Terminal J with jumper disconnected.	A	FM Antenna	Adjust for maximum output. (See Note 2.)
10	FM	87 mc	30% FM	300 ohm Carbon resistor	Antenna Terminal J with jumper disconnected.	L ₁	FM Antenna	Adjust for maximum output. (See Note 2.)
11	Repeat operations 9 and 10 if an appreciable change is made in the adjustment of L ₁ .							

NOTE 1—Adjust input voltage to give approximately 4 volts AVC before final adjustment is made. For steps 4 and 6—Voltmeter common lead to chassis. For step 5—Voltmeter common lead to point "Y" on wiring diagram. The desired zero position is at the point where the meter indicates a polarity change from plus to minus or vice versa.

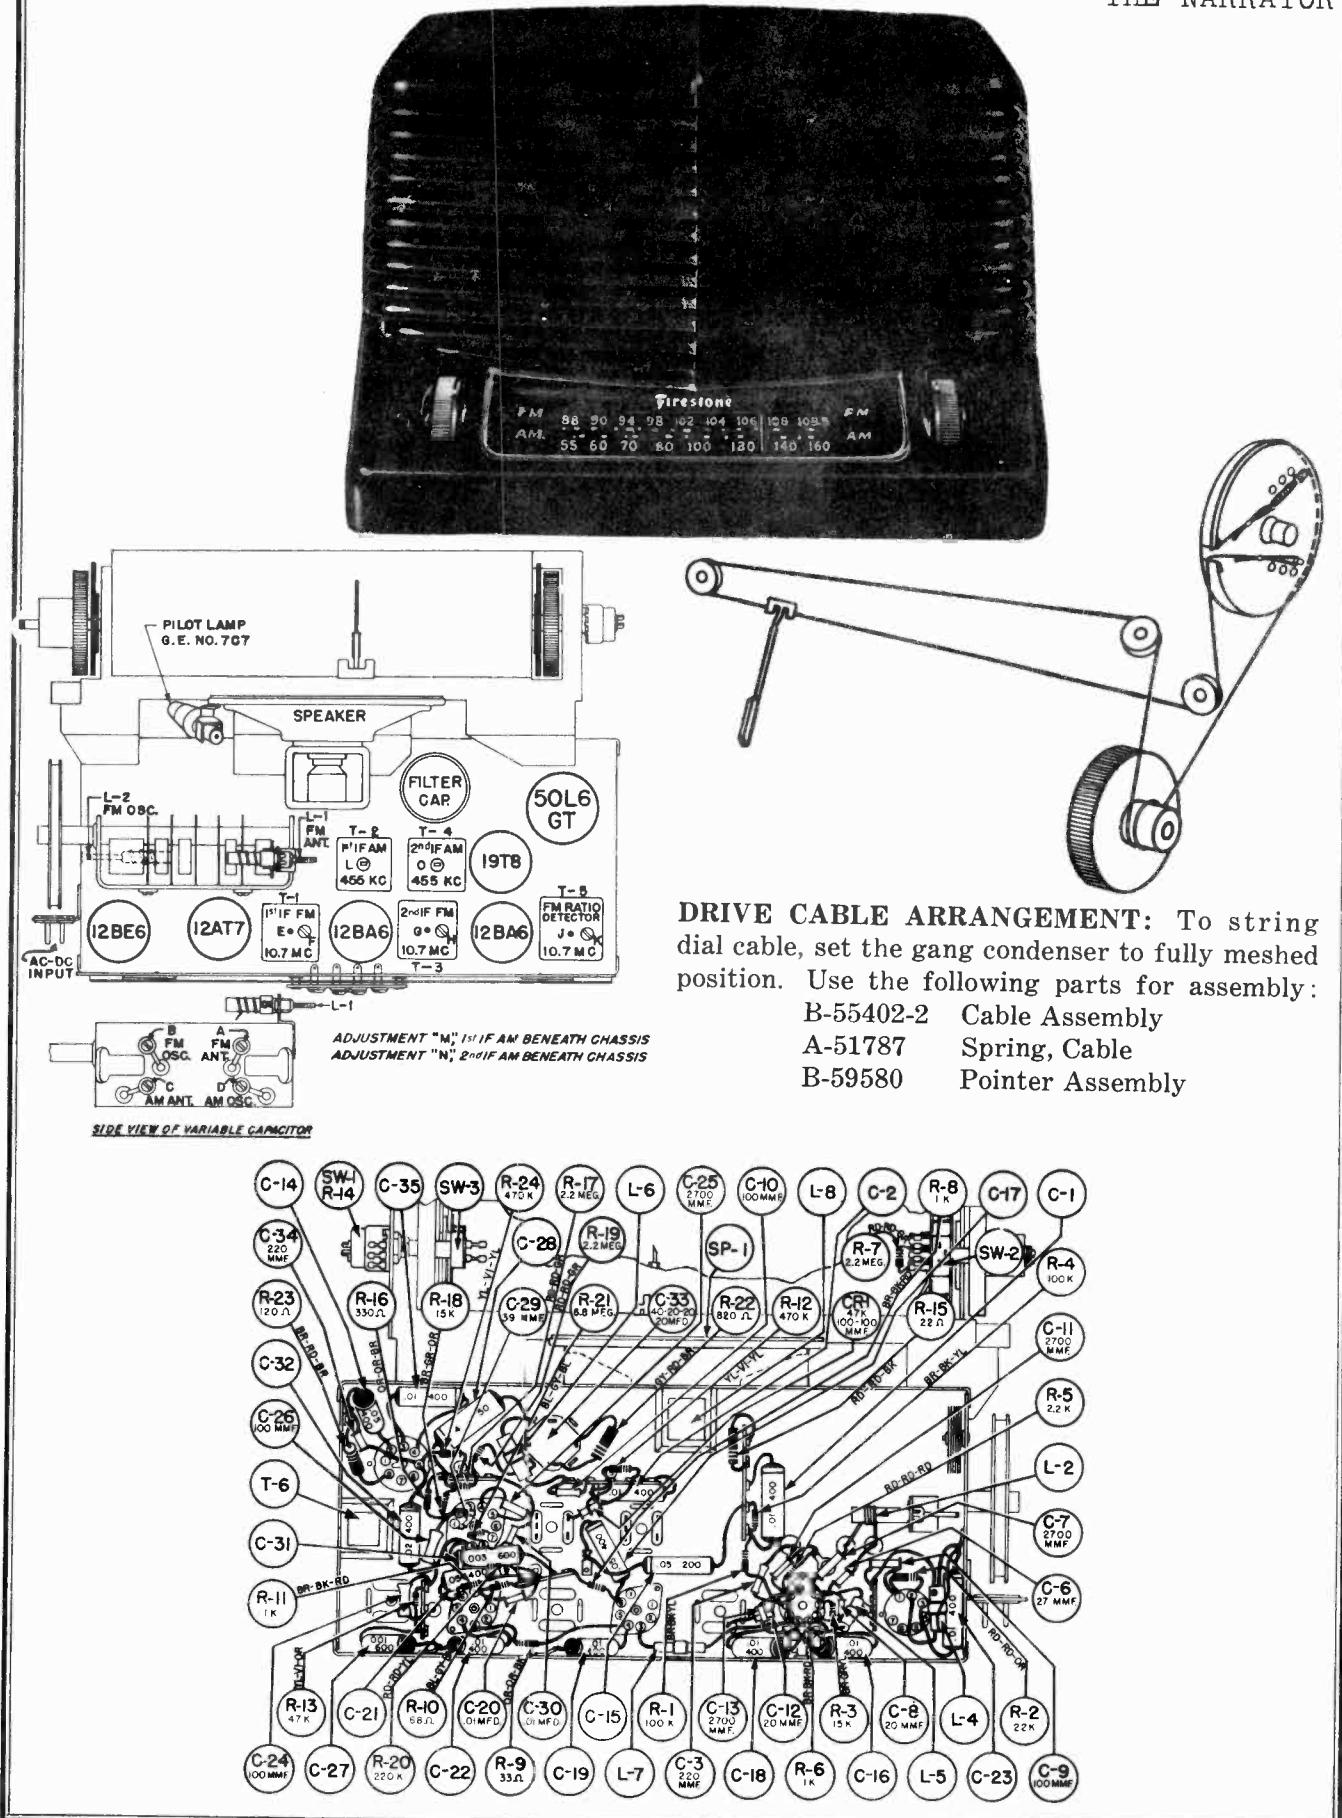

NOTE 2—For all tests requiring an FM signal, the generator output (22.5 kc deviation, 400 cycles) must be adjusted to give approximately 50 milliwatts receiver output before final adjustments are made.

Oscilloscope Alignment—FM Band

These curves were obtained under ideal conditions and show curves to be expected. They should be duplicated as nearly as practicable.

FM IF ALIGNMENT

1. Equipment required: Oscilloscope, 10.7 MC sweep generator, voltmyst, and RF signal generator.
2. Set band switch in FM position.
3. Make connection from vertical deflection amplifier of oscilloscope to pin #3 of 6H6 discriminator tube. Make certain that the 4MFD electrolytic condenser is disconnected from this same circuit. It is necessary that the lead to the oscilloscope be shielded, of low total capacity, and connection to receiver isolated by means of a 1 meg. resistor.
4. Connect sweep generator to last FM IF grid through a .1 MFD coupling capacitor.
5. Load primary of discriminator transformer with resistor of approximately 3900 ohms. Back out secondary slug (top slug) as far as it will turn. Align primary (bottom slug) to obtain curve similar to figure 1. This does not constitute a final alignment of discriminator, but is a convenient expedient to assist in IF alignment.
6. Shift connection of sweep signal generator to the grid of the second FM IF tube.
NOTE: As alignment moves from stage to stage, reduce input instead of reducing oscilloscope gain.
7. Align third FM IF transformer for a symmetrical flat top pattern. (Fig. 2).
8. Shift signal generator to the grid of the first IF tube.
9. Align second IF transformer in same manner as described in Section 7.
Note that the width of the nose of the curve is the same as before, but the sides have become steeper, as in Fig. 3.
10. Connect the signal generator to the grid of the converter tube grid in series with 10,000 ohm resistor and a .1MFD capacitor, or loosely couple by stray capacity of an insulated wire.
11. Align first FM IF transformer in the same manner as in Section 7.
Note that the sides of the curve have further steepened, but that the nose of the curve has retained approximately the same width as in Fig. 3.

12. Connect 4 MFD electrolytic capacitor that was previously disconnected, and take off load resistor on discriminator primary.
13. Connect oscilloscope to audio output terminal of discriminator. There are several points where contact can be made and can be identified as the circuit connected to the terminal on the terminal board (nearest the discriminator transformer) to which the shielded lead is connected.
14. With sweep signal input to converter grid, align discriminator transformer for conventional discriminator pattern, as in Fig. 4.
15. Connect signal generator to converter tube grid through .1MFD capacitor. An unmodulated signal input of 65 microvolts at 10.7 MC should develop .55 volt rise on the AVC line with voltohmyst connected to AVC line through 1 megohm resistor.

Alternate FM IF Alignment Procedure

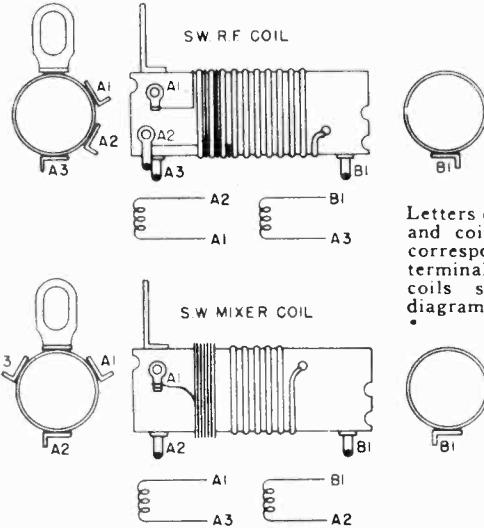

1. Connect voltohmyst or high resistance voltmeter on AVC line (Pin 3 on 6H6 socket) through 1 meg. resistor. Connect AM signal generator, set at 10.7 MC, to grid on 6SK7 which feeds diode transformer. Connect output meter on voice coil of speaker.
2. Turn bottom slug (nearest the chassis) of disc. transformer out as far as possible.
3. Tune top slug of disc. transformer for maximum output (negative voltage) on the voltmeter.
4. Connect generator to grid of second IF amplifier.
5. Detune slug of 3rd IF transformer under chassis by turning out as far as possible
6. Tune top slug for maximum voltage, next tune bottom slug for maximum voltage. In each step do not use an input greater than necessary to give three volts AVC.
7. Connect signal generator to grid of first IF amplifier.
8. Detune bottom FM slug (nearest corner of can) by turning out as far as possible.

9. Tune top slug (nearest corner of can) for maximum voltage, next tune bottom slug for maximum voltage.
10. Connect signal generator to 6AG5 converter grid and tune first IF transformer as above.
11. With generator still hooked to 6AG5 grid and modulated with 400 cycles, about 200 microvolts input, adjust slug next to chassis on disc. transformer for minimum output voltage on output meter which is on voice coil.

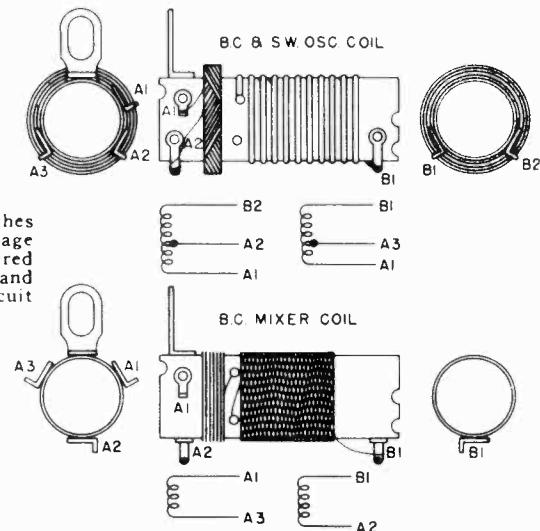

FM RF Alignment

1. Equipment Required:
 - a. RF Signal Generator. Range 88 to 108 MC.
 - b. Output Meter.
 - c. Insulated Screw Driver.
2. Connect RF signal generator in series with 330 ohm carbon resistor to "high" side of FM antenna socket. Connect output meter across voice coil of speaker.
3. Set tuning control for pointer to calibrate at 108.
4. Apply 108 MC Signal.
5. Set converter and antenna trimmers at minimum capacity.
6. Adjust oscillator trimmer by tuning from maximum capacity to first signal that is heard, and peak for maximum output.
7. Adjust antenna and converter trimmers for maximum output.
8. Set tuning controls so dial pointer calibrates at 88 MC.
9. Apply 88 MC signal.
10. Adjust oscillator, converter, and antenna slugs to maximum output.
11. Repeat operations 3 to 10 inclusive.
NOTE: The degree of adjustment required in the tuning of the oscillator slug will determine the number of times operations 3 to 10 must be repeated until no further gain in sensitivity is obtained.
12. Carefully tune across the entire FM band for the observance of the dead or weak spots that may be a resultant of improper alignment or defective components. This can be determined by carefully noting the degree of receiver noise, that is, high noise generally is accompanied by good sensitivity.

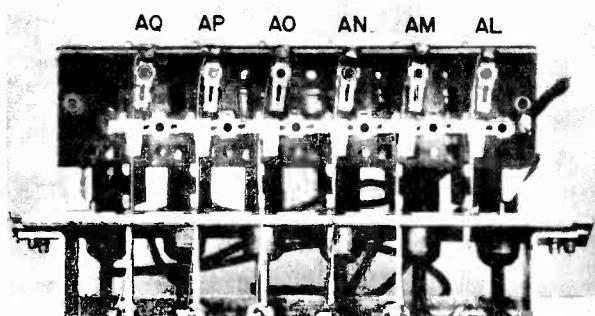

RF, OSCILLATOR AND MIXER COILS

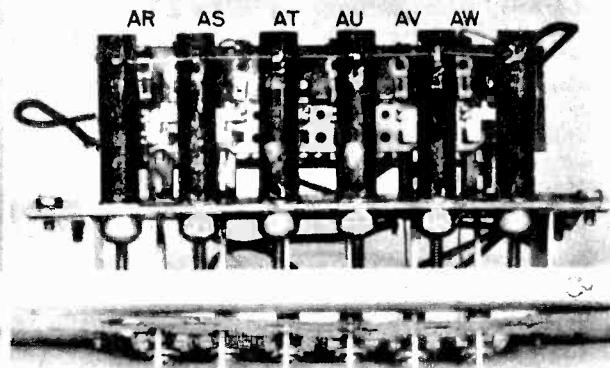

Letters on terminals of switches and coils shown on this page correspond to similarly lettered terminals on the switches and coils shown in the circuit diagram.

TOP VIEW OF PUSHBUTTON ASSEMBLY

BOTTOM VIEW OF PUSHBUTTON ASSEMBLY

Alignment of AM Bands

EQUIPMENT REQUIRED

A calibrated signal generator having fundamental frequencies from 455 Kc to 16 MC. In addition to the signal generator a crystal calibrator is a great convenience.

The indicating device for showing correct alignment may be a high resistance A.C. voltmeter, a vacuum tube voltmeter or a Cathode Ray oscilloscope.

The A.C. voltmeter can be used either across the voice coil of the loud speaker or if the meter range is high enough, from the plate to plate in the output stage (don't forget a condenser (0.1 Mfd.) to keep the D.C. out of the meter).

Special care must be employed when aligning the short wave band, for the adjustment of the shunt trimmer affects the adjustment of the series pad. At the high frequency end of the band it is possible to peak the oscillator trimmer (and the pad at the low frequency end) at the image so in the alignment instructions we have indicated the fundamental frequency and the correct oscillator setting for the image so by resetting the signal generator it is possible to see if the alignment is correctly made. In each case, the image is found at a frequency 910 Kc. higher than the fundamental. Trimmers are accessible by removing top radio panel, eliminating necessity of chassis removal from cabinet.

TABULATION FOR AM ALIGNMENT

STEPS	CONNECT GENERATOR	SET GENERATOR AT	SET GANG AT	ADJUST	TO OBTAIN
1	Set Tone and Volume Controls at Maximum				
2	Through .1 Mfd.			2nd. I.F. A.M. Slugs

MODEL 4-A-26,
THE NEWSCASTER

ALIGNMENT PROCEDURE

- With the gang condenser fully meshed, the dial pointer should be in the position indicated by the last mark below 55 on the dial. If it is set incorrectly, release the pointer clip on dial cord and reposition pointer.
- Remove chassis from cabinet by taking out two screws which hold chassis to bottom of cabinet. Solder approximately 8" of insulated wire to any B- connection (see voltage chart on Page 6 for convenient B- location).
- Connect ground lead of signal generator to B- through a 0.25 Mfd. condenser.
- Connect output meter across speaker voice coil (terminals at back of speaker) or from plate of type 50L6GT tube to B- through a 0.1 Mfd. condenser.
- Set volume control at maximum volume position and use a weak signal from the signal generator.

STAGE GAIN MEASUREMENT PROCEDURE

REQUIRED INSTRUMENTS: The amount of amplification or "gain" of each of the stages of this receiver may be measured with an A.C. Vacuum Tube Voltmeter or a "channel" type instrument containing a tuned and calibrated amplifier.

PROCEDURE: It is exceedingly important to adhere to the procedure outlined below since the accuracy of these measurements will be affected to a considerable extent by the failure to establish proper operating conditions.

1. Be sure that R.F. and I.F. stages are carefully and accurately aligned by utilizing the alignment procedure given on page 4.
2. Connect Signal Generator as shown below.
3. The values of stage gain which are given here were measured with a fixed bias of 3 volts on the control grids of all R.F. and I.F. tubes which are connected to the A.V.C. circuit. Therefore, these values are not intended to indicate the full capability of a stage but they will serve as a convenient basis for determining proper operation. In order to duplicate the fixed bias voltage, connect the negative terminal of a 3 volt battery to the A.V.C. lead at terminal "D" of antenna coil and then connect positive battery lead to B— in the receiver chassis.
4. Set Signal Generator for operation at 600 Kc with 400 cycle modulation and carefully tune radio receiver to this signal by using an output meter to indicate peak output. If a local station interferes, set generator to a nearby frequency and re-tune the receiver.
5. R.F. and I.F. circuits are slightly de-tuned when contact is made with an instrument probe and this action, which is indicated by a change in the output meter reading, may seriously affect the gain measurement. Therefore, it is important to adjust the associated circuit trimmer for a maximum output meter reading and to set the input signal level to a convenient reference point on the gain measuring instrument while the probe is making contact. After removing the probe it is again necessary to adjust the trimmer so as to obtain the same output meter reading and thereby assure that the signal voltage at the specified point has not changed as a result of circuit de-tuning.
6. When using a "channel" type instrument, carefully tune it for maximum output at desired frequency before making measurements.

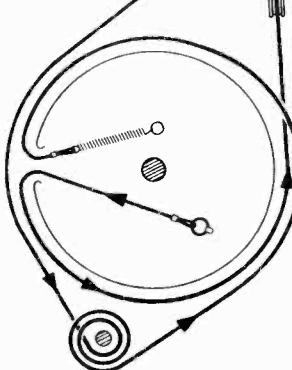

DIFFERENCES in tube characteristics, tolerance of parts, adjustment of tuned circuits and variations in line voltage will influence stage gain. These factors should be given due attention in event the gain of a stage varies extensively from the values shown above.

DIAL AND POINTER
DRIVE CORD
ARRANGEMENT

To string dial cord, set gang condenser to fully meshed position and use following parts:

114955 Clip on end of cord
117057 Cord (4½ feet)
119087 Ring for dial cord
161384 Tension Spring

ALIGNMENT PROCEDURE

1. Remove chassis and loop antenna from cabinet (do not remove loop of wire stapled to cabinet). Wind one turn of insulated wire around frame of antenna so as to provide a means of coupling it to the signal generator. Space chassis approximately same distance from loop as when installed in cabinet. Connect plug on loop antenna cable to socket at rear of chassis. Brown lead in antenna cable (which was connected to loop of wire stapled to cabinet) should now be connected to one end of new coupling turn on frame of loop.
 2. With the gang condenser fully meshed, dial pointer should be in the position indicated by the last division below 55 on the dial. If it is set incorrectly, release pointer clip on dial cord and reposition pointer.
 3. Connect output meter across speaker voice coil.
 4. Connect the ground lead of the signal generator to the receiver chassis.
 5. Set volume control at maximum volume position and use a weak signal from the signal generator.
 6. Push in the manual button and leave it in that position throughout the alignment procedure.

IMPORTANT:—Align this receiver in exactly the order shown below. Broadcast band must be aligned before short wave bands.

DUMMY ANT. IN SERIES WITH SIGNAL GENERATOR	CONNECT HIGH SIDE OF SIGNAL GENERATOR TO	SIGNAL GENERATOR FREQUENCY	BAND SWITCH POSITION	RECEIVER DIAL SETTING	TRIMMER NUMBER	TRIMMER DESCRIPTION	TYPE OF ADJUSTMENT
.1 MFD. Condenser	Trimmer on rear section of gang	455 KC	"A" Broadcast (counter- clockwise)	Any point where it does not affect the signal.	1-2	2nd I.F.	Adjust for maximum output. Then repeat adjustment.
500 MMFD. Condenser	Coupling turn on Loop Frame		"A" Broadcast (counter- clockwise)		3-4	1st I.F.	
500 MMFD. Condenser	Coupling turn on Loop Frame	1500 KC	Broadcast (counter- clockwise)	1500 KC	5	Broadcast Oscillator (Shunt)	Adjust for maximum output
500 MMFD. Condenser	Coupling turn on Loop Frame	1500 KC	"A" Broadcast (counter- clockwise)	Tune to 1500 KC Generator Signal	6	Broadcast R.F.	Adjust for maximum output
500 MMFD. Condenser	Coupling turn on Loop Frame	1500 KC	"A" Broadcast (counter- clockwise)	Tune to 1500 KC Generator Signal	7	Broadcast Antenna	Adjust for maximum output
500 MMFD. Condenser	Coupling turn on Loop Frame	600 KC	"A" Broadcast (counter- clockwise)	Tune to 600 KC Generator Signal	8	Adjustable core of Broadcast Oscillator Coil.	Adjust for maximum output. Try to increase output by rotating core in and out and retuning receiver dial until maximum out- put is obtained.
500 MMFD. Condenser	Coupling turn on Loop Frame						
		Repeat adjustments of trimmers 5, 6 and 7 at 1500 Kc. Then re-check adjustment of trimmer 8 at 600 Kc.					
400 OHM Carbon Resistor	Coupling turn on Loop Frame	15.5 MC	"B" Short wave (center)	15.5 MC	9	S.W. ("B") Oscillator	Adjust for maximum output. Check to see if proper peak was obtained by tuning in image at approx. 14.6 MC. If image does not appear, realign at 15.5 MC, with trimmer screw farther out. Re- check image.
400 OHM Carbon Resistor	Coupling turn on Loop Frame	15.5 MC	"B" Short wave (center)	Tune to 15.5 MC Generator Signal	10	S.W. ("B") Antenna	Adjust for maximum output. Try to increase output by detuning trimmer and retuning receiver dial until maximum output is obtained.
400 OHM Carbon Resistor	Coupling turn on Loop Frame	9.5 MC	"C" Short wave (clockwise)	9.5 MC	11	S.W. ("C") Oscillator	Adjust for maximum output. Check to see if proper peak was obtained by tuning in image at approx. 8.6 MC. If image does not appear, realign at 9.5 MC, with trimmer screw farther out. Recheck image.
400 OHM Carbon Resistor	Coupling turn on Loop Frame	9.5 MC	"C" Short wave (clockwise)	Tune to 9.5 MC Generator Signal	12	S.W. ("C") Antenna	Adjust for maximum output. Try to increase output by detuning trimmer and retuning receiver dial until maximum output is obtained.

SIDE OF CHASSIS

TOP VIEW OF CHASSIS

1. Set Band Switch to "A" position and allow set to operate 15 minutes before making any adjustments.
 2. Note two rows of adjusting screws on back of radio chassis which are visible and accessible through top opening in cabinet back (entire cabinet back may be removed if desired by taking out screws around the sides). Each vertical pair of adjusting screws is used to tune-in a station for one of the push-buttons. A label under the row of screws specifies the frequency or tuning range that each screw will cover.
 3. Select five powerful nearby stations and obtain their frequencies from your local newspaper. Be sure that the frequency of each station falls within the frequency range of the adjusting screw which will be used to tune-in that station.
 4. Before disturbing adjusting screws, return to front of radio and push in "MANUAL" button. Then tune-in the lowest frequency station in the group of 5 that you selected. Listen to the program so that you can identify it later.

APPROXIMATE STAGE GAIN DATA

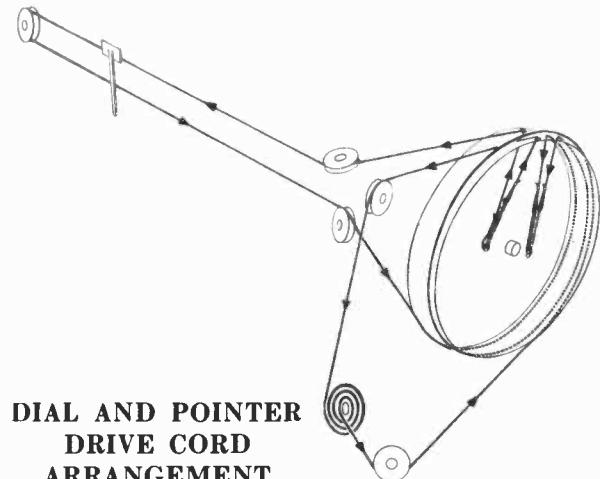

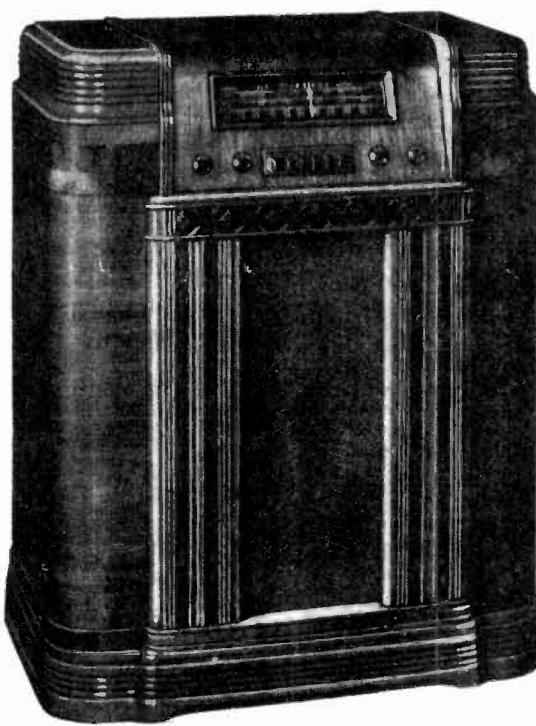

Be sure R.F. and I.F. stages are accurately aligned before measuring gain. R.F. gains can be measured with a "channel" type instrument containing a tuned and calibrated R.F. amplifier. A vacuum tube voltmeter may be used for audio gain measurements. Observe following precautions:

1. For all gain measurements connect signal generator as shown. Use 600 KC. signal with 400 cycle modulation (use nearby frequency if local station interferes.)
2. For R.F. and I.F. measurements connect negative terminal of a 3 volt battery (two 1½ volt cells in series) to A.V.C. lead at lug "P" of S.W. Antenna Coil and positive terminal to chassis. This provides a definite operating point. **IMPORTANT:** Disconnect battery when measuring audio stage gains.
3. Be sure radio is carefully tuned to generator signal (use weak signal for sharp tuning.)
4. When using a "channel" type instrument carefully tune it for maximum output at desired frequency before making measurements.

The R.F. and I.F. stage gains shown below are less than under normal operating conditions due to the use of 3 volts fixed bias in order to establish a definite operating point. Therefore, these values are not intended to indicate the full capability of a stage.

Differences in tube characteristics, tolerance of parts, adjustment of tuned circuits, and variations of line voltage will influence stage gain. Accuracy of measurements is dependent upon careful tuning of receiver to generator signal and experience in using your test equipment. These factors may create considerable variation in gain measurements.

DIAL AND POINTER
DRIVE CORD
ARRANGEMENT

To string dial cord, set gang condenser to fully meshed position and use following parts:

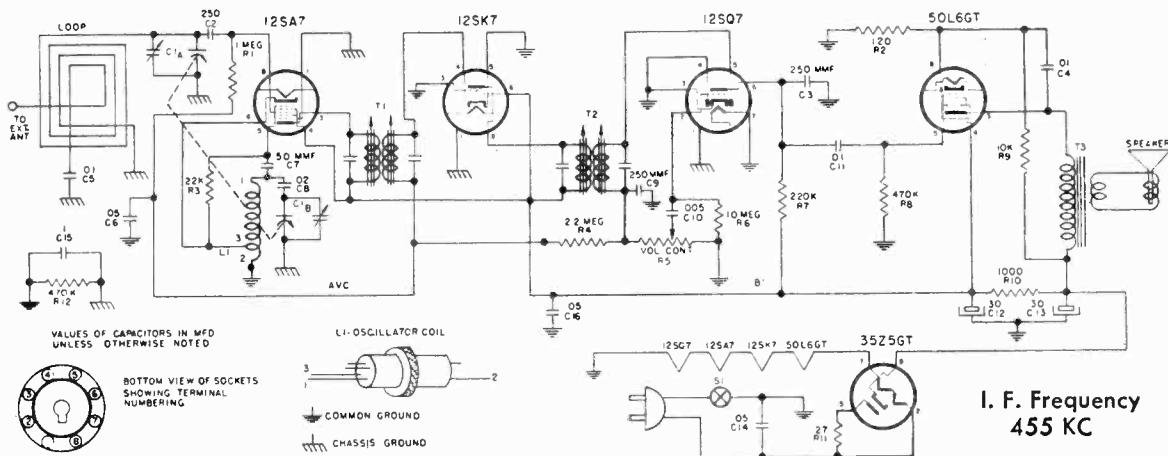

113177 Tension Spring
114955 Clip on end of cord
119087 Ring for dial cord
117057 Cord (9 feet)
Pointer drive 5 feet
Gang drive 4 feet

AUDIO OSCILLATION

The audio system of this receiver utilizes a two stage type of inverse feed-back arrangement and, should it ever be necessary to replace the speaker or output transformer, it is important to maintain a definite phase relationship in this feedback circuit. If the connections to the output transformer are reversed or if the feed-back connection is made to the wrong side of the output transformer secondary, the system will become regenerative instead of degenerative. Under such conditions audio oscillation may result. If that occurs, oscillation may be prevented by reversing the connections to the primary of the output transformer.

MODEL 4-A-61,
THE CAMEO

ALIGNMENT PROCEDURE

The alignment should be made with volume control fully on, and the output from the signal generator as low as possible, to prevent A.V.C. action from interfering with correct alignment.

For alignment procedure read tabulations from left to right, and make the adjustment marked (1) first, (2) next, (3) third. Before starting alignment:

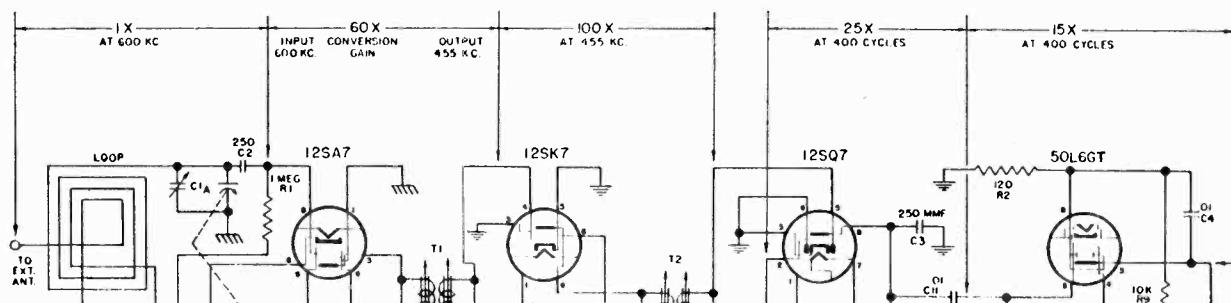

- Check tuning dial adjustment by tuning gang condenser until plates touch maximum capacity stop (completely in mesh) at which point the dial pointer must be exactly even with the last mark at the low frequency end of the dial calibration. If dial pointer is incorrectly set, release pointer clip on dial cord and reposition pointer.
- Use an accurately calibrated test oscillator with some type of output measuring device.
- PLACE LOOP ANTENNA IN THE SAME POSITION IT WILL BE IN WHEN THE SET IS IN THE CABINET.

Steps	Set receiver dial to:	TEST OSCILLATOR			Refer to parts layout diagram for location of trimmers mentioned below:
		Adjust test oscillator frequency to:	Use dummy antenna in series with output of test oscillator consisting of:	Attach output of test oscillator to:	
1	Minimum capacity (fully open)	455 K.C.	.1 MFD. condenser	High side to grid of tuning condenser. Low side to common negative. (through .25 MFD. Cond.)	Adjust each trimmer on the second I. F. transformer for maximum output—then adjust each trimmer on the first I. F. transformer for maximum output.
2	Minimum capacity (fully open)	Exactly 1630 K.C.	.00025 MFD. condenser	Receiver antenna lead. common negative	Adjust 1630 K.C. oscillator trimmer for maximum output.
3	Approx. 1400 K.C.	Approx. 1400 K.C.	.00025 MFD. condenser	Receiver antenna lead. common negative	While rocking gang condenser adjust 1400 K.C. antenna trimmer for maximum output.

Before proceeding with stage measurements be sure the receiver is properly aligned. R.F. gains can be measured by a "channel" type instrument containing a tuned and calibrated R.F. amplifier. A vacuum tube voltmeter may be used for audio gain measurements. Observe the following precautions:

- For all gain measurements connect the "high" side of a signal generator to the antenna lead through a .00025 mica condenser. The ground side of the signal generator should be connected to common negative. Use a 600 KC signal with 400 cycle modulation (use nearby frequency if local station interferes).
- Be sure radio is carefully tuned to generator signal (use weak signal for sharp tuning.)
- When using a "channel" type instrument carefully tune it for maximum output at desired frequency before making measurements.

Stage gain measurements can be influenced by the normal manufacturers tolerances allowed in parts, differences in individual tube characteristics, the adjustment of the tuned circuits and variations in line voltage. Careful tuning of the receiver as well as experience in using your test equipment will determine the accuracy of the measurements taken. Due to all of these factors, the stage gains shown in the above diagram are approximate values rather than absolute as it is possible to introduce many variations in these measurements.

THE FIRESTONE TIRE & RUBBER CO.

STAGE GAIN MEASUREMENT PROCEDURE

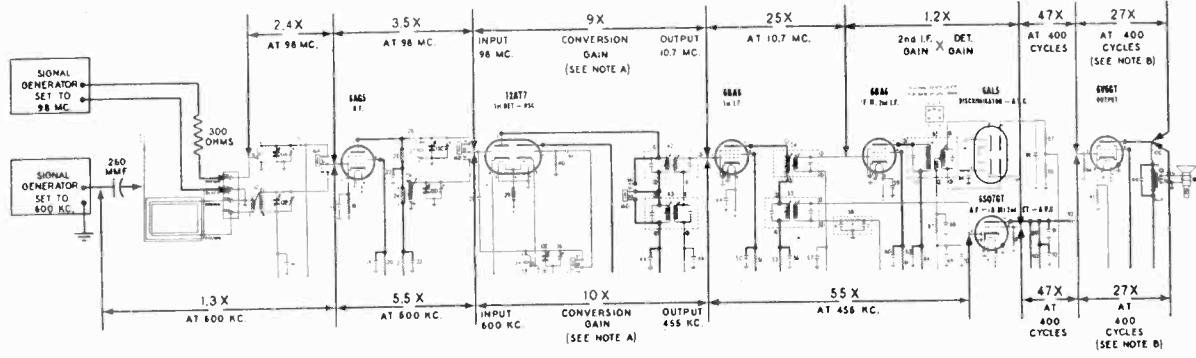

REQUIRED INSTRUMENTS: The amount of amplification or "gain" of most of the stages of this receiver can be measured with an A.C. Vacuum Tube Voltmeter of the high frequency type. An AM (600 KC.) as well as an FM (98 MC.) signal source is required. For gain measurements in the FM antenna—FM converter—FM 1st I.F. stages, a microvolt calibrated FM signal generator should preferably be used.

PROCEDURE: It is exceedingly important to adhere to the procedure outlined below since the accuracy of these measurements will be affected to a considerable extent by the failure to establish proper operating conditions.

1. Be sure that R.F., I.F. and Discriminator stages are carefully and accurately aligned by utilizing the alignment procedure given in this manual.
2. Connect Signal Generator as shown below. Note that generator connections differ for "AM" and "FM" measurements.
3. For "AM" measurements, set signal generator to 600 KC. (400 cycle modulation) and then carefully tune radio receiver to this signal by using an output meter to indicate peak output. If a local station interferes, set generator to a nearby frequency and re-tune the receiver.
4. For "FM" measurements, set signal generator to 98 MC. (400 cycle modulation with 22½ KC. deviation) and then carefully tune radio receiver to this signal by using a D.C. Vacuum Tube Volt-

meter as an output indicator—meter must be connected between pin No. 7 of 6AL5 tube and chassis. If a local station interferes, set generator to a nearby frequency and re-tune the receiver.

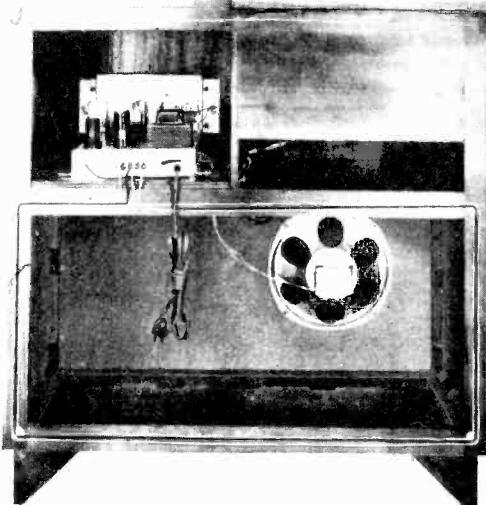

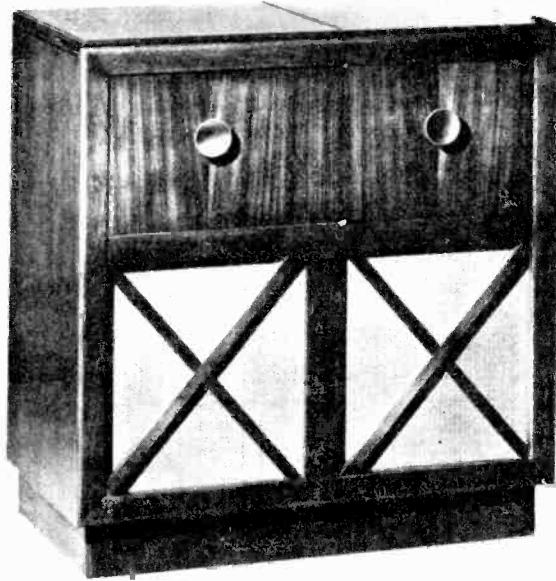

5. The values of stage gain which are given here were measured with a fixed bias of -3 volts on the control grids of all R.F. and I.F. tubes which are connected to the A.V.C. system. Therefore, these values are not intended to indicate the full capability of a stage but they will serve as a convenient basis for determining proper operation. In order to duplicate the fixed bias voltage, connect the negative terminal of a 3 volt battery to both A.V.C. supply lines by effecting a common connection to terminal 4 of 2nd FM-I.F. transformer and terminal 2 of 1st AM-I.F. transformer. Then connect the positive battery lead to the receiver chassis.
6. R.F. and I.F. circuits are slightly de-tuned when contact is made with an instrument probe and this action, which is indicated by a change in the output meter reading, may seriously affect the gain measurement. Therefore, it is important to adjust the associated circuit trimmer for a maximum output meter reading and to set the input signal level to a convenient reference point on the gain measuring instrument while the probe is making contact. After removing the probe it is again necessary to adjust the trimmer so as to obtain the same output meter reading and thereby assure that the signal voltage at the specified point has not changed as a result of circuit de-tuning.

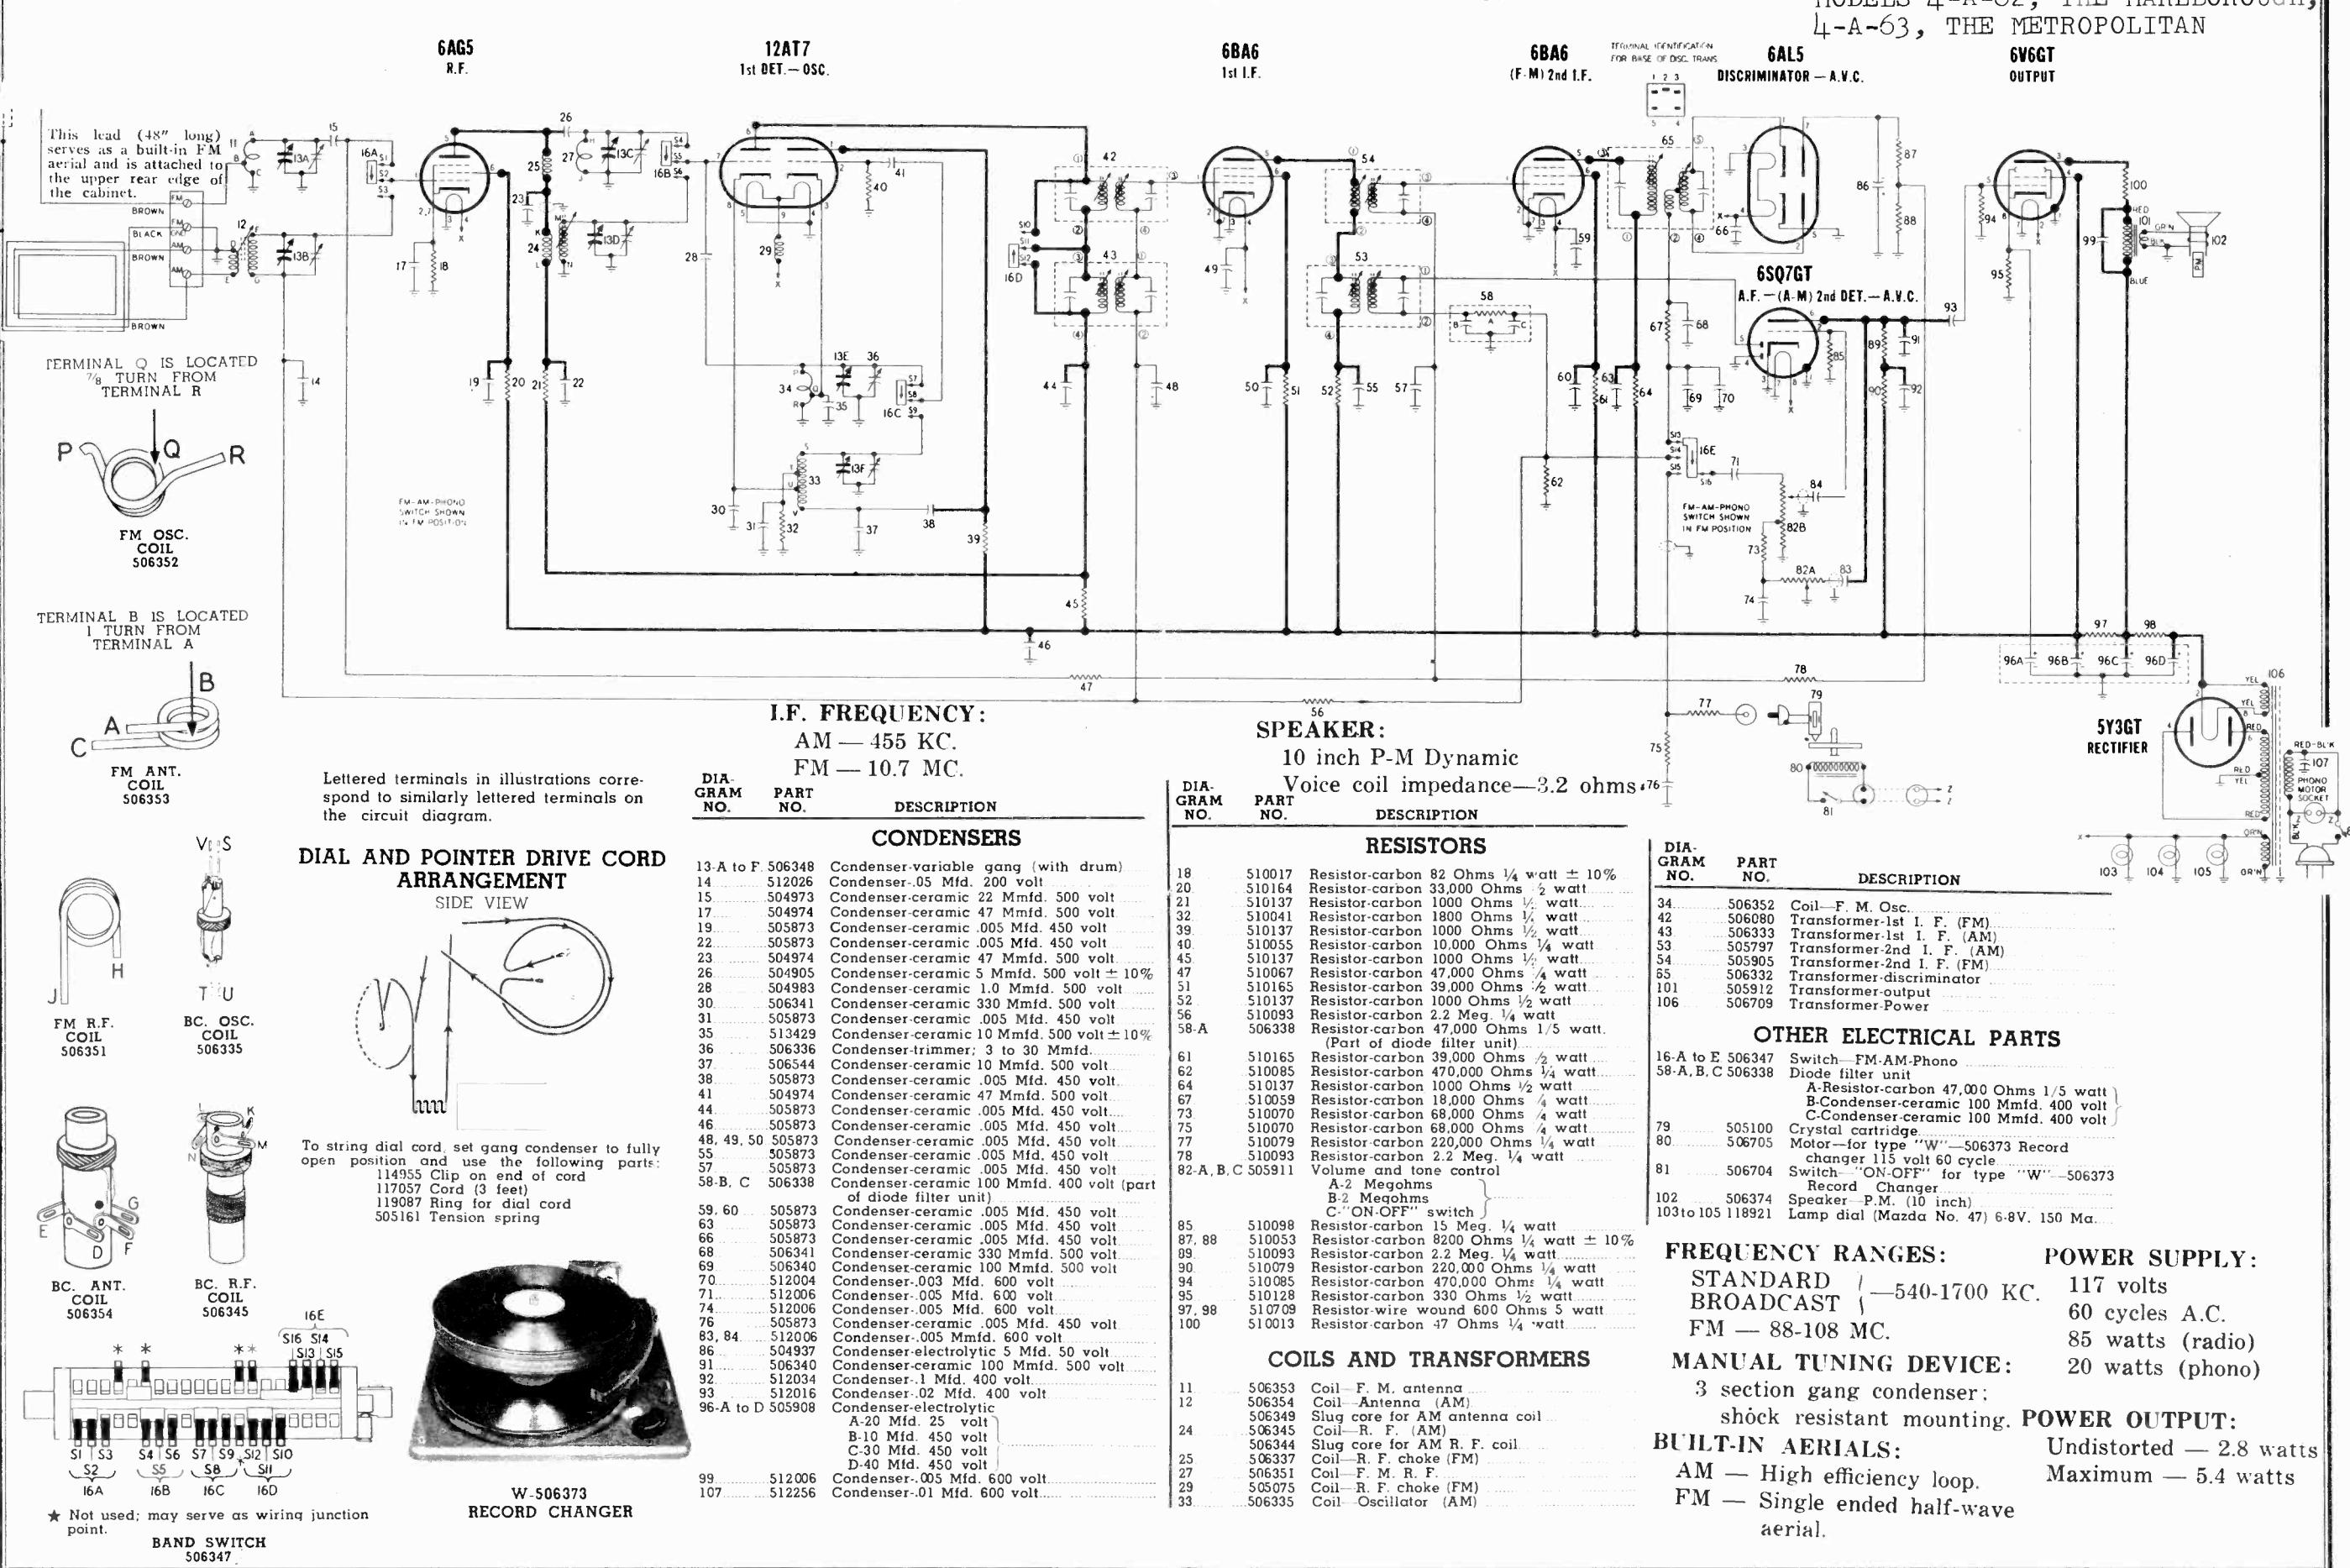

NOTE A: Short oscillator grid (pin 2 of 12AT7) to ground when measuring input voltage at signal grid (pin 7) of 12AT7 tube.

NOTE B: Measured with input voltage of 0.3.

DIFFERENCES in tube characteristics, tolerance of parts, adjustment of tuned circuits and variations in line voltage will influence stage gain. These factors should be given due attention in event the gain of a stage varies extensively from the values shown above.

BROADCAST BAND -"AM"-ALIGNMENT PROCEDURE

1. Disconnect leads from FM-AM aerial terminal strip (labeled FM-FM-AM-AM) at back of chassis; also disconnect speaker leads and phono plugs. Remove chassis and speaker. If desired, allow speaker to remain in cabinet and connect to receiver by extension leads.
 2. Stand chassis on one edge so that all trimmers are accessible.
 3. Loop aerial leads (on cabinet) do not have to be connected to terminal strip on chassis while I. F. stages are being aligned. Before starting alignment of Ant., R.F., and Osc. stages, reconnect all four aerial leads to chassis—do not attempt to use extension leads; place chassis as close as required to cabinet so that connections may be made direct to aerial terminal strip at back.
 4. With the gang condenser fully meshed, dial pointer should be in the position indicated by the last division below 55 on the dial. If it is set incorrectly, hold tuning shaft steady and reposition pointer.
 5. Connect an output meter across speaker voice coil, or from plate of 6V6GT tube to chassis through a 0.1 Mfd. condenser.
 6. Connect ground lead of signal generator to the receiver chassis.
 7. Set volume control at maximum volume position and use a weak signal from the signal generator.

DUMMY ANT. IN SERIES WITH SIGNAL GENERATOR	CONNECT HIGH SIDE OF SIGNAL GENERATOR TO	SIGNAL GENERATOR FREQUENCY	BAND SWITCH POSITION	RECEIVER DIAL SETTING	TRIMMER OR SLUG NUMBER	TRIMMER DESCRIPTION	TYPE OF ADJUSTMENT

THE FIRESTONE TIRE & RUBBER CO.

FREQUENCY MODULATION—"FM"—ALIGNMENT PROCEDURE USING A VACUUM TUBE VOLTMETER AND AM SIGNAL GENERATOR)

INSTRUMENTS: Although it is preferable to use an FM generator and an oscilloscope, reasonably accurate alignment is obtainable when using a conventional AM generator and vacuum tube voltmeter providing proper care is exercised in adjusting the discriminator circuit trimmer.

IMPORTANT: When using an AM signal generator, it should be capable of producing fundamental frequencies of 10.7 MC and 88 MC to 108 MC — avoid using an AM generator which produces signals in the 88 to 108 MC range by using harmonics higher than the second. Generators which are dependent upon third, fourth or fifth harmonics for output frequencies of 88 to 108 MC will generally produce undesirable spurious beat signals with the local oscillator in the receiver and alignment will be exceedingly difficult.

1. If alignment of both AM and FM channels is required it is necessary to align the AM channel first, then align the FM channel as instructed in chart below (AM alignment procedure is given on the preceding page).

SIGNAL GENERATOR CONNECTIONS	FREQUENCY & TYPE OF MODULATION	VACUUM TUBE VOLTMETER CONNECTIONS	RECEIVER DIAL SETTING	TRIMMER OR SLUG NUMBER	TRIMMER DESCRIPTION	TYPE OF ADJUSTMENT AND OUTPUT INDICATION
Connect high side in series with an .01 Mfd condenser to lug on trimmer No. 17 at top of gang (see illustration on page 9 for location of trimmer). Connect ground lead to receiver chassis in vicinity of 12AT7 tube.	10.7 MC AM signal may be 400 cycle modulated.	Connect common (or ground) terminal of meter to receiver chassis. D.C. probe lead of meter is then connected to pin No. 7 of the 6ALS tube.	Any position where it does not affect the signal.	11	Discriminator Primary	Adjust these trimmers for maximum meter reading the output voltage will be of negative polarity.
				12 and 13	2nd I.F.	
				14 and 15	1st I.F.	

Recheck adjustment of trimmers No. 10 and No. 11^a to be sure that both are set as accurately as possible to obtain the specified output indication.

Connect generator "high" side in series with a 300 ohm carbon resistor to end terminal marked "FM" on strip at back of chassis. Generator ground lead must connect to next terminal marked "GND".	106 MC AM signal may be 400 cycle modulated.	Connect common (or ground) terminal of meter to receiver chassis. D.C. probe lead of meter is then connected to Pin No. 7 of the 6AL5 tube.	106 MC	16	Oscillator Trimmer	Set trimmer No. 16 to receive 106 MC. signal as indicated by maximum meter reading. IMPORTANT: It will be noted that there are two different settings of trimmer No. 16 at which the 106 MC. signal will be received; always select the trimmer setting which is nearest to the low capacity end of its range.
Same as above	Same as above	Same as above	Tune to 106 MC. generator signal.	17	R.F. Trimmer	Adjust trimmer No. 17 for maximum meter reading.
				18	Antenna Trimmer	Adjust trimmer No. 18 for maximum meter reading.
				14 and 15	1st I.F.	Recheck adjustment of these trimmers for maximum meter reading.

Check calibration and tracking of receiver with input signals of 90 and 98 MC. If difference between dial pointer setting and 90 or 98 MC. calibration mark does not exceed \pm 0.3 MC. and antenna and R.F. circuits are tracking properly, then alignment may be considered satisfactory and no further adjustment is necessary.

When the calibration error is greater than \pm 0.3 MC. it is advised

- ment of the trimmers it will then be necessary to adjust the spacing of the gang condenser plates.

 2. If pointer falls below the 90 MC. calibration point, it will be necessary to push the windings together on the FM oscillator coil. Then repeat the two preceding adjustments of trimmers 16, 17 and 18 at 106 MC. Should it be found impossible to obtain the 106 MC. signal at the proper point on the dial by adjustment of the trimmers it will then be necessary to adjust the spacing of the gang condenser plates.
 3. Correction for mistracking of antenna and R.F. may be accomplished by adjusting coil turns and gang plate spacing in the same manner as outlined above for the oscillator stage.

THE FIRESTONE TIRE & RUBBER CO.

MODELS 4-A-62,
4-A-63

FREQUENCY MODULATION—"FM"—ALIGNMENT PROCEDURE
(USING AN OSCILLOSCOPE AND FM "SWEEP" GENERATOR)

INSTRUMENTS: Alignment of the FM circuits in this receiver can be most conveniently accomplished with an FM signal generator. When using this type generator, the output indicator must be an oscilloscope.

1. If alignment of both AM and FM channels is required it is necessary to align the AM channel first, then align the FM channel as instructed in chart below (AM alignment procedure is given on page 8).
2. Disconnect leads from FM-AM aerial terminal strip (labelled FM-FM-AM-AM) at back of chassis; also disconnect speaker leads and phono plugs. Remove chassis and speaker. (If desired, allow speaker to remain in cabinet and connect to receiver by extension leads.)
3. With the gang condenser fully meshed, dial pointer should be in the position indicated by the last division below 88 on the dial.

If it is set incorrectly, hold tuning shaft steady and reposition pointer.

4. A specific setting of the receiver volume control is not required, however, it will be found convenient to leave it in the maximum volume position so that alignment signals will be audible even though the output indication is obtained by an oscilloscope connected to points in the discriminator circuit.
5. Dress FM circuit leads as short and straight as possible, particularly those in the oscillator circuit. I.F. plate and grid leads should also be kept short and straight.
6. Set band switch to the FM (extreme counter-clockwise) position.
7. Set tone control to fully counter-clockwise position.

SIGNAL GENERATOR CONNECTIONS	FREQUENCY & TYPE OF MODULATION	OSCILLOSCOPE CONNECTIONS	RECEIVER DIAL SETTING	TRIMMER OR SLUG NUMBER	TRIMMER DESCRIPTION	TYPE OF ADJUSTMENT AND OUTPUT INDICATION
Connect high side in series with an .01 Mfd condenser to lug on trimmer No. 17 at top of gang (see illustration on page 8 for location of trimmer). Connect ground lead to receiver chassis in vicinity of 12AT7 tube.	10.7 MC FM signal should preferably be modulated ± 400 KC.	Connect vertical amplifier "high" lead to junction of resistor No. 67 (18000 ohms) and condenser No. 70 (.003 Mfd.) which are in discriminator output circuit. Connect scope ground lead to receiver chassis.	Any position where it does not affect the signal.	10	Discriminator Secondary	Before attempting to adjust trimmer No. 10, set trimmers No. 11, 12, 13, 14 and No. 15 for approximately maximum sound output from the speaker (output meter not required). This is done to obtain sufficient signal for an oscilloscope pattern of desirable amplitude when making the following discriminator trimmer adjustment. Adjust setting of trimmer No. 10 until a pattern similar to that shown in Fig. 2 appears on the screen. If pattern does not remain stationary operate sweep frequency control on 'scope and also "sync" control until desired result is obtained. Correct setting of trimmer No. 10 is obtained when crossover point "B" (Fig. 2) is centrally located in both the horizontal and vertical directions; in addition that portion of the curve between "A" and "C" should be as linear (straight) as possible.
Same as above	Same as above	Same as above	Same as above	11	Discriminator Primary	Adjust these trimmers for maximum amplitude and steepness of that portion of the pattern between "A" and "C" (see Fig. 2).
				12 and 13	2nd I.F.	
				14 and 15	1st I.F.	
Recheck adjustments of trimmers No. 10 and No. 11 to be sure that both are set as accurately as possible to obtain correct cross-over point or symmetry of pattern.						
Connect generator "high" side in series with a 300 ohm carbon resistor to end terminal marked "FM" on strip at back of chassis. Generator ground lead must connect to next terminal marked "GND".	106 MC FM signal should preferably be modulated ± 400 KC.	Same as above	106 MC	16	Oscillator Trimmer	Adjust trimmer No. 16 to obtain the symmetrical pattern shown in Fig. 2. Correct setting of trimmer No. 16 is obtained when cross-over point in pattern is centrally located. IMPORTANT: It will be noted that there are two different settings of trimmer No. 16 at which the desired 'scope pattern can be obtained—always select the trimmer setting which is nearest to the low capacity end of its range.
Same as above	Same as above	Same as above	Tune to 106 MC. generator signal.	17	R.F. Trimmer	Adjust trimmer No. 17 for maximum amplitude of pattern.
				18	Antenna Trimmer	Adjust trimmer No. 18 for maximum amplitude of pattern.
				14 and 15	1st I.F.	Recheck adjustment of these trimmers for maximum amplitude of pattern.
<p>Check calibration and tracking of receiver with input signals of 90 and 98 MC. If difference between dial pointer setting and 90 or 98 MC. calibration mark does not exceed ± 0.3 MC. and antenna and R.F. circuits are tracking properly, then alignment may be considered satisfactory and no further adjustment is necessary.</p> <p>Where the calibration error is greater than ± 0.3 MC. it is advisable to make the following adjustments:</p> <ol style="list-style-type: none"> 1. If pointer falls above the 90 MC. calibration point, it will be necessary to slightly spread the windings of the FM oscillator coil. Then repeat the two preceding adjustments of trimmers 16, 17 and 18 at 106 MC. Should it be found impossible to obtain the 106 MC. signal at the proper point on the dial by adjustment 						
<p>of the trimmers it will then be necessary to adjust the spacing of the gang condenser plates.</p> <ol style="list-style-type: none"> 2. If pointer falls below the 90 MC. calibration point, it will be necessary to push the windings together on the FM oscillator coil. Then repeat the two preceding adjustments of trimmers 16, 17 and 18 at 106 MC. Should it be found impossible to obtain the 106 MC. signal at the proper point on the dial by adjustment of the trimmers it will then be necessary to adjust the spacing of the gang condenser plates. 3. Correction for mistracking of antenna and R.F. may be accomplished by adjusting coil turns and gang plate spacing in the same manner.
